The visually impaired project examines the design of a single-family home in Logan Square, Chicago, for an adult experiencing cataract-related low vision and his family. The research explores how a typical urban neighborhood, rather than segregated special-needs housing, can support safe, independent living for people with visual impairment. The home is designed for Ned and Sam, a same-sex couple raising two adopted daughters, who need an environment where Ned can navigate confidently while their children grow up in a diverse and supportive community. Logan Square was selected for its strong walkability, creative culture, and inclusive social identity. Chicago's public transit network and Logan Square's direct access to buses, the Blue Line, and bike lanes provide predictable mobility for someone with low vision. Parks like Palmer Square Park, Unity Park, and The 606 offer safe, consistent spatial patterns that help with orientation and create daily outdoor routines for the family. The neighborhood's artsy, culturally vibrant character and established LGBTQ+ presence strengthen social belonging. Case Study Family Integration + LGBTQ+ Inclusivity, drawn from research on visually impaired adults living in mixed-use urban communities, shows that neighborhoods with dense amenities, predictable street grids, and active public spaces significantly improve navigation confidence and reduce social isolation. The findings support the idea that individuals with cataracts benefit most from environments where transit, parks, and services are integrated into everyday circulation rather than separated into specialized districts. These insights directly inform the home's interior design strategies, which emphasize high-contrast wayfinding, layered lighting, clear circulation paths, and family-centered interaction

zones to reduce visual strain and increase safety. Overall, the research concludes that Logan Square's walkability, inclusivity, transit access, and community character combined with evidence from contemporary case studies make it an ideal location for this visually impaired parent and his family to call home.

Abstract Name: Are Picture Filters Pulling Their Weight?

Pittsburgh had problems with lead in drinking water – so much so that the city provided ZeroWater filters to the residents. Pittsburgh is not the only city with lead problems; many people use water filters to remove lead and other toxins from their drinking water. The big three water filter companies are Brita, PUR, and Zero. These filters work by using a combination of mechanical filtration (physically trapping the particles), sorption (accumulation of materials on a surface), and molecular sieves (a material that separates and traps materials). The purpose of this experiment is to test these filters' ability to filter lead over the filter's advertised life span and beyond. Deionized water (no detectable lead) was mixed with lead nitrate to create a solution of 10 parts per billion (ppb) of lead; the USEPA action level is 15 ppb. We poured a quantity of lead solution through the filters over the advertised life span volume and beyond. Samples were taken periodically. The samples were tested for lead using an atomic absorption spectrometer, a device that measures concentration of elements by measuring the amount of light absorbed. We have evidence that so far the filters have removed most of the lead; however, some removal has been inconsistent. The research is ongoing, samples from the first 5 liters have been tested and all came back below the detection limit for lead. This was an expected result because the filters are still new. Samples will be collected every 10 liters and tested for lead with an end goal of pouring the advertised amount of water and beyond.

Abstract Name: Potentiometric Analysis of Biofluids via Fully 3D Printed Sensors

Research in the field of point-of-care (POC) sensing aims to address global healthcare concerns while aiming for affordable and highly functioning alternatives to commercially available devices. POC sensors reduce patient stress from unnecessary practices, provide constant monitoring, and prompt reliable identification of different illnesses. Ion-selective electrodes (ISEs) offer a robust ability of adaptability, reliable and fast analysis with high sensitivity and selectivity for various analytes. Conventional methods for ISEs fabrication rely on polyvinyl chloride (PVC) which poses a challenge with respect to mass production. Additive manufacturing, such as 3D Printing, offers a refined approach for ISE fabrication due to precision, rapid fabrication, customization, and cost-effectiveness. Using a Fused Deposition Modelling (FDM) 3D printer, a customized solid-contact transducer can be fabricated which can then be paired with an ion-selective membrane, printed using stereolithographic (SLA) 3D printer, resulting in a fully 3D-printed solid-contact ISE. Using this approach, potentiometric sensors for diverse electrolytes have been fabricated and

characterized by various approaches, including potentiometric calibration, selectivity analysis, long-term stability tests, water layer tests, and shelf-life.

Abstract Name: What Families Wish They Had Known: Research on Immediate End-of-Life Care Needs in Cancer Patients

Objective: We aimed to explore families' of children dying of cancer and advanced heart disease's immediate end-of-life needs. **Methods:** A secondary qualitative analysis was conducted of 110 interviews (n = 55 Oncology; n = 55 Advanced Heart Disease) with bereaved parents whose children died of cancer or cardiovascular disease in Alabama (n = 57), Massachusetts (n = 24), and California (n = 29). The cohort was racially diverse (45 White [41%], 43 Black [39%], and 15 Hispanic [14%]); the interviews were initially conducted between 2017-2024 to evaluate families' perspectives on quality of end-of-life care; they were recorded and transcribed. In this analysis, quotes related to immediate end-of-life needs were identified inductively by AM with regular review for face validity by LH. Then AM inductively developed an initial codebook that was iteratively refined by the whole research team. **Results:** Immediate End-of-Life needs fall into five domains: **Last Minute Medical Decisions:** At end-of-life parents regularly had to make final decisions regarding resuscitation, withdrawal of treatment, and hospice transition. This was challenging due to limited guidance, and inconsistent communication. **Critical Importance of the Environment:** Families valued private, quiet spaces, familiar staff, and opportunities for physical contact. **Psychosocial and Financial Resources:** Access to counseling, sibling engagement, and memory-making activities were inconsistent and gaps in these services limited adequate emotional support. **Logistical and Financial Burdens:** Families experienced logistical challenges such as travel, coordinating childcare, and navigating hospital processes, along with financial strain from missed work and out-of-pocket expenses, all of which intensified stress during their child's final days. **Clear and Compassionate Communication:** Across domains, clear and compassionate communication from healthcare providers was most influential as transparency and empathy eased decision-making, while inconsistency deepened distress. **Conclusion:** This study identified critical end-of-life needs of families whose child was dying of cancer and AHD, which can inform end-of-life education and supportive services

Abstract Name: The Role of xCT Protein Expression in Epstein-Barr Virus Infected Cells

The Epstein-Barr virus (EBV) is one of the most common viruses in the world, estimated to have infected

over 95% of the world's population. EBV is the causative agent of infectious mononucleosis, or “mono,” and is associated with several cancer types, including nasopharyngeal, gastric, and Burkitt lymphoma. As a member of the herpesvirus family, EBV persists in the body for a lifetime, evading immune system detection by entering an inactive, latent state after infection. EBV can reactivate and exit this inactive state in response to various stimuli, including stress and chemical exposure. During EBV reactivation, EBV spreads to other cells. The mechanism behind EBV reactivation is not completely understood. Understanding how EBV inhibitors and activators impact host and viral genes and proteins has important pharmaceutical and clinical implications. When EBV-infected cells were treated with EBV inhibitors, the gene that encodes the xCT protein, SLC7A11, was upregulated. xCT is a membrane transport protein of the dimeric amino acid cystine. Cystine feeds into downstream reactions that promote cell survival through antioxidation and preventing programmed cell death. To investigate the potential role of xCT in EBV inhibition, EBV-infected Burkitt lymphoma cells were treated with EBV inhibitors and harvested at various time points to establish a timeline for xCT expression relative to EBV activation. xCT protein expression and EBV activation were measured using Western blotting. xCT was upregulated by two EBV inhibitors, indicating a plausible role for xCT in restricting EBV reactivation. Future research establishing the importance of xCT to EBV inhibition, as well as the mechanism behind xCT-mediated EBV inhibition, is needed. Understanding how host and viral proteins and genes interact is critical for developing effective therapeutic interventions for EBV and related cancers.

Abstract Name: Mast cell contributions to connective tissue weakness

Hypermobile Ehlers-Danlos syndrome (hEDS) and Hypermobility Spectrum Disorder (HSD) are disorders of connective tissue laxity characterized by instability of bodily structures. Their underlying mechanisms remain poorly understood, but emerging evidence implicates protease-mediated collagen dysregulation as a likely pathological driver. Mast cells—reported to be hyperactive in approximately one-third of hEDS/HSD patients—release and activate proteases that may contribute to this weakening. To evaluate this possibility, we have optimized fabrication of fibroblast–collagen constructs that we will co-culture with activated mast cells in the presence or absence of protease inhibition. We will assess matrix organization using anisotropy values obtained from collagen visualization with Sirius Red and quantification using ImageJ. We expect that mast cell presence will reduce collagen fiber alignment only in cultures without protease inhibition. Our goal is to investigate whether mast cell-derived protease activity contributes to connective tissue weakness in hEDS and HSD.

Abstract Name: Phenotypic and Molecular Characterization of Metal Resistance in Soil Microbes

The soil microbiome is a diverse and vital community of organisms that aid in necessary processes like nutrient cycling, digesting organic molecules, and improving soil fertility. Many commercial fertilizers include metal micronutrients (Cu^{2+} , Zn^{2+} , Mn^{2+} , and Fe^{2+}) to support plant growth, but the effect of these metals on soil-dwelling bacteria is understudied. In this study, we characterized metal tolerance in bacteria isolated from agricultural soils and investigated molecular mechanisms of metal resistance. We cultivated 132 bacterial isolates from agricultural plots receiving different fertilizer treatments (macronutrients only, macro- and micronutrients, and no amendments) to characterize their metal tolerance. Using 16S rRNA sequencing and phylogenetic analyses, we identified 47 unique species from 17 different genera. We then characterized cellular responses to excess levels of Zn^{2+} in twenty isolates. We found a range of phenotypes depending on the organism, identifying metal resistance in *Chryseobacterium* sp. and *Stenotrophomonas maltophilia*, which exhibited cell proliferation with the highest zinc concentration tested. Some organisms were sensitive to all concentrations tested (e.g. *Prestia megaterium* and *Bacillus amyloliquefaciens*) while others exhibited a concentration-dependent phenotype (e.g. *Bacillus albus* and *Pseudomonas granadensis*). Because metal ions are essential for the structural stability and catalytic function of ribosomes, we investigated the impact of excess metals on ribosome assembly and function. We hypothesized that metal-resistance organisms have evolved adaptations that reduce metal binding to the ribosome. We used sucrose gradient density ultracentrifugation to assess relative levels of ribosomal complexes. Supporting our hypothesis, we found little to no effect on the abundance of actively translating ribosomes in the metal-resistant organisms. This research demonstrates how commercial fertilizers affect the soil microbiome, reveals a range of metal tolerant microbes, and explores mechanisms that enable ribosomes to adapt to metal stress. These findings are critical for developing sustainable agricultural practices and understanding microbial resilience in contaminated environments.

Abstract Name: Microplastics in Croplands: Input, Key Effects on Yields and Carbon Dynamics, and Implications for Human Health

Microplastics (MPs) are plastic particles ranging from 1 nm to 5 mm according to the US EPA, with Polyethylene (PE) and Polypropylene (PP) accounting for over 51% of global plastic production. Global plastic production has already reached 367 million tons by 2020. With the increasing plastic use, MPs have become a significant environmental and health concern. A structured literature review analyzing 40 research articles was performed over 2 semesters. This involved annotation and evaluation of peer-reviewed studies, with articles selected for their relevance to cropland soil contamination, plant interaction, and human exposure risks. By integrating both agricultural research and human health studies, this review bridges microplastic contamination in croplands with the effects of human exposure. The objective was to examine MP sources in croplands, their effects on yield and nutrition, soil integrity, and risks to human health. MPs cause mechanical damage to plant roots, alter soil properties, and disrupt microbial communities. Studies have shown PP reducing soybean growth by 12% and decreasing nitrogen fixation by 17.1-27.5%, impacting soil microbial interaction. Additionally, studies with various soil samples have indicated an increase of 54.3% CO_2 and 9.7% CH_4 emissions. Studies have also found contamination of 50-300,000 MP particles/g in fruit and 20-70,000 MP particles/g in vegetables, raising concerns about human consumption. The human health risks include oxidative stress, immune dysfunction, reproductive toxicity, and potential carcinogenicity. Recent studies have found MPs in human blood, breast milk, placenta, and various tissues. Overall, MPs continue to be a growing concern. MPs contaminate soils, infiltrate plant tissues, impact ecosystem functions, and create risks to humans through consumption of contaminated foods. Therefore, understanding MPs interaction with our crops and human health is crucial to evaluating the overall impact of their presence, and developing strategies for reducing future risk.

Abstract Name: Studying with Music: A Behavioral Analysis of Music on Individual Attentiveness During a Stressful Task

Background music is widely used by students during academic work, yet research remains mixed on whether certain genres improve or impair cognitive performance and attention. Prior literature highlights that music engages neural pathways involving the auditory cortex, frontal lobe, and amygdala, influencing emotional arousal and attentional control. With this study, we wanted to explore how classical music, popular music, and silence influence calculation fluency and attentiveness in college students. This project utilizes a within-subjects experimental design in which each participant completes three math problem sets under all auditory conditions. All participants will experience each condition in randomized order to minimize sequencing effects. Performance will be measured by the number of items completed accurately within a two-minute interval. Post-task surveys will assess demographics, attentional traits, and self-reported concentration levels. We predicted that classical music would result in the highest task accuracy due to its consistent tempo and calming properties, while popular music, with lyrics and dynamic variation, may divide attentional resources and reduce performance. However, preliminary findings suggest the opposite trend, with participants performing best under popular music conditions. These early results indicate that familiarity and cultural exposure may moderate the cognitive effects of music more strongly than previously expected. This research may inform evidence-based study recommendations and provide insight into attention-enhancing strategies for students, particularly those with attentional challenges. As music is an accessible, low-cost tool, identifying optimal auditory environments could support academic focus, improve learning outcomes, and guide future interventions within educational settings.

Abstract Name: China's Information Operations in the Indo-Pacific: Understanding PRC Influence and U.S. Strategic Gaps

Chinese information operations (IO) have become a critical instrument of statecraft in the Indo-Pacific region, allowing the People's Republic of China (PRC) to influence political environments, shape public narratives, and coerce regional actors without crossing the threshold into armed conflict. This project examines how Chinese IO targeting third-party nations unveil the coercive strategy of Beijing's model of influence and evaluates how U.S. Indo-Pacific Command (INDOPACOM) can better compete in this domain. Drawing on existing literature of the PRC's "Three Warfares" doctrine: public opinion, psychological, and legal warfare, this research analyzes how China leverages state media, social-media manipulation, and AI-enabled disinformation to advance its political goals. Using case studies of Taiwan and Thailand, the project evaluates how these tools operate in distinct political contexts. The experiences of these countries illustrate

how China employs both rapid, high-intensity disinformation targeting elections and slower, long-term influence through soft power, social influence and cultural networks. This research assesses structural limitations within the U.S. response, including fragmented communication practices, slow interagency coordination, and gaps in INDOPACOM's capacity to detect and counter emerging IO threats. To address these gaps, the study proposes three measures: integrating IO with Public Affairs structures, training Public Affairs and Intelligence officers to operate with an information-domain mindset and leveraging private sector and AI capabilities for rapid analysis and counter-messaging. Strengthening these areas enhances U.S. and allied resilience and improves their ability to compete decisively in the information domain.

Abstract Name: Assessing Nutrient Export from Bioretention Basin Soils under Different Treatments

Bioretention basins are designed to improve stormwater quality, but their effectiveness can be compromised if soils release nutrients such as nitrate and phosphorus back into standing water. Understanding how vegetation and organic amendments influence nutrient leaching is important for improving basin performance. This study tests whether soils collected from a bioretention basin release nutrients during a 72 hour saturation period and whether mulch, organic material, or vegetation alter the amount of nitrate and phosphorus leached. Soil from an established bioretention basin was homogenized and placed into 16 oz mesocosms fitted with a side port tubing for leachate collection. Seven treatments were established: bare soil, soil with mulch, soil with organic material, soil with a native plant called frog fruit (*Phyla nodiflora*), soil with a non-native plant called rescue grass (*Bromus catharticus*), and soils containing either plant species combined with organic material. Simulated stormwater was added to each mesocosm and allowed to stand for 72 hours. Afterward, the leachate, along with input water and water only controls, was filtered and analyzed for nitrate and phosphorus. We expect bioretention basin soils to increase nitrate and phosphorus concentrations during the 72-hour saturation period, with bare soil and organic material treatments likely showing the highest nutrient levels. We also expect that mesocosms containing vegetation, especially the native plant species treatment, will reduce nutrient leaching compared to non-vegetated treatments. In contrast, rescue grass may show weaker nutrient retention due to its rapid growth and shallower root structure. Once simulated storm pulses are repeated, we anticipate nutrient release to decline over time as soil nutrient pools stabilize. These patterns will help identify which soil amendments or plant types most effectively limit nutrient output from bioretention basins.

Abstract Name: Interactive Air Quality Dashboard for North Carolina: A Data-Driven Tool for Environmental

Monitoring and Community Decision-Making

Understanding local air quality is essential for public health, yet many regions lack accessible tools that help communities interpret pollutant trends in a meaningful way. This project addresses the central research question: How can volatile organic compound (VOC) data be transformed into an interactive, user-friendly platform that supports environmental awareness and evidence-based decision-making across North Carolina? Although several environmental monitoring systems exist, most are either too technical for general audiences or lack county-level interactivity. This work aims to contribute a more intuitive and community-focused solution. The dashboard compiles publicly available VOC measurements from the Environmental Protection Agency (EPA) monitoring stations across all North Carolina counties. Data is cleaned, aggregated, and processed using Python, with visualizations built in Dash. The methodological approach includes time-series analysis to detect seasonal patterns, comparative visualization across counties, and threshold detection to highlight potential health risks. A search-based location selector allows users to instantly explore conditions for any county, while interactive charts and tooltips present pollutant patterns in an accessible format. An information button provides compound descriptions to help non-experts understand the significance of each measurement. Preliminary results show clear seasonal variations in VOC levels and noticeable differences across counties, emphasizing the need for localized environmental monitoring tools. The dashboard is expected to enhance public understanding by translating complex environmental data into digestible insights. It also lays the foundation for expanding the platform to include predictive modeling, additional pollutant types, and nationwide visualization capabilities.

Abstract Name: Balancing It All: A Survey for Parents

Parents often focus on their child's wellbeing instead of considering themselves as well (Bogdan, 2025). The parents might only be focused on the tasks that need to be completed with the child and completing household tasks (Bogdan, 2025). Lack of self-care is a problem due to even if the child's needs are met, the parents still need to care for themselves (Mollborn, 2011 p.33). Parental burnout is a national problem because parents are not taking care of themselves, only the children (Beresin, 2024). Roughly 63 million parents living in the United States reported being stressed (Beresin, 2024). The research focuses on how parents practice self-care and how it's perceived affects their child(ren). The student researchers reviewed 10 peer reviewed articles relating to how different types of self care impact parents. The student researchers identified Lazarus's Stress and Coping Theories and Bowlby's Attachment Theory to help guide the foundation of their research to help strengthen the study. A parent's mental and physical health matters too. Social workers can educate parents on how to set healthy boundaries and cope with stress. In the study being conducted the student researchers collect data on parental burnout and ask them how parents practice self-care. The student researchers explain why self-care is important. The student researchers create a solution that helps parents improve their wellbeing. The student researchers employ a mix of purposive sampling which will target parents who attend choices clinic and convenience sampling which will target participants we can easily reach. This approach informs the study by identifying common practices, parents engagement in self-care, and highlights areas where additional support may be needed. The results provide valuable data to describe current behaviors and guide recommendations for promoting self-care among parents.

Abstract Name: An Analysis on the Effect of Information Volume on Driver Comprehension of Tunnel Clearance-Related Message Signs

Tunnel clearance-related message signs are a type of traffic control device used to inform drivers of the maximum height a vehicle cannot surpass to pass through a tunnel. Such information is essential for maintaining efficient traffic flow, but there have been many cases of over height vehicles striking tunnels despite warnings. This phenomenon could potentially be attributed to a lack of comprehension of tunnel clearance-related message signs. Previous studies on traffic sign comprehension have found that many drivers are unable to recognize various road signs. Additionally, increased perceptual load has been shown to have detrimental effects on drivers' behavior, such as reducing speed and increasing lane shifting. There are a number of factors influencing drivers' perception and comprehension of road signs, such as color, size, and information volume. These are factors that have all been examined with the use of changeable message signs (CMS), a traffic control device used to provide drivers with information about road conditions or public safety announcements. Studies on drivers' comprehension of CMS have largely found a significant effect of information volume, with increased volume being associated with reduced comprehension. Although many studies have been conducted on traffic sign information volume (TSIV) and CMS, few studies have focused on tunnel clearance-related message signs. The present study aims to determine the optimal information volume on tunnel-clearance related message signs using redesigns of traditional signs which will be presented as CMS. In this two-part study, participants will first be surveyed on their comprehension of traditional tunnel clearance-related message signs compared to the redesigns. Following the survey, the redesigned signs with the highest comprehension scores will be superimposed onto footage of a video-game based driving simulation, which participants will interact with and answer questions about to further assess comprehension and perceived compliance with CMS.

Abstract Name: Bridging the Gap: Improving Latina Involvement in Medical Research

Latinas are severely underrepresented in medical research, yet they remain one of the fastest-growing populations in the U.S. The lack of participation leads to a limited understanding of health disparities and makes it difficult to develop adequate medical treatments for this minority population. Increasing Latina participation is valuable to improve inclusivity in scientific findings. The purpose of this study was to examine the perceptions and attitudes of foreign- and US-born Latinas about participating in medical research and providing biological samples. Women were recruited through snowball sampling and with the help of two partner organizations. Twenty-five women who live in Virginia participated in this study – 10 participated in 2 focus groups and the rest in one-on-one interviews over Zoom. Questions included what they thought medical and genetic research entailed, their willingness to donate different biological samples, questions or concerns that they might have, and ideas they could share on how to successfully recruit Latinas into genetic studies. Interviews were audio-recorded, transcribed in their original language, and coded using Dedoose

qualitative analysis software. Data analysis is ongoing, but our preliminary findings shed light on three themes which will make the basis of this presentation. First, the participants described their lack of information regarding opportunities in medical research, the process and what it entails, and the benefits of participation. Second, aspects of mistrust in both the healthcare system and confidentiality of information were critical concerns expanded in the interviews. Third, despite the concerns expressed, our participants also expressed interest in improving Latino health outcomes through their participation, which highlights the role of altruism in their decision to potentially take part in research studies. Based on the insights gathered from these interviews, we will provide recommendations to recruit Latinas and improve their rates of participation in medical research.

Abstract Name: Gene Expression Differences in HIV Infection: A Computational Analysis

HIV is a destructive retrovirus that can lay dormant within cells, before eventually leading to AIDS in infected individuals. Though effective prevention of HIV is available commercially, effective cure of ongoing infection is absent. The gene expression pathways affected by HIV infection are not yet well understood and could provide insight into improved treatment avenues, therefore this project sought to identify the specific cellular processes affected by infection of the HIV virus. Differing gene expression levels as compared to standard controls were analyzed in multiple cell types experimentally infected with a modified HIV-1 type B strain. RNA was collected and shotgun sequenced to generate reads. These reads were pieced together computationally through mapping to the human exome. Using R software available on the VCU HPRC, the featureCounts program was run to quantify the raw amount of RNA mapped to each gene. This count data was then analyzed with DESeq2 to determine the most differentially expressed genes between HIV infected cells and uninfected controls. A text summary of the data was uploaded to g:Profiler to perform a functional enrichment analysis. Data for the most common locations, structural changes, and biological processes affected were collected and analyzed. Preliminary results showed that pathways, such as the lymphocyte proliferation pathway, were significantly enriched in the HIV infected sample, demonstrating that HIV is able to directly influence host cell behavior. Further results may provide insight into alternative gene expression pathways affected by HIV and pave the way for more effective cure of the infection.

Abstract Name: Increasing Birth Weight and Gestational Age Data for Undocumented Mexican Immigrant Births: Understanding How to Improve Healthcare Access for Undocumented Mexican Immigrants in South Texas

The population of undocumented immigrants from Mexico has been steadily growing in Texas. Accompanying this growth is a health crisis, whereby undocumented Mexican immigrants, who already have

limited access to health coverage, experience poorer health outcomes. This is especially noted in the vulnerable pregnant population, who experience neonatal low birth weights and shorter gestational periods as compared to non-immigrants. Adequate prenatal care may serve to address these neonatal insufficiencies and FQHCs may be a recourse for undocumented immigrants who are otherwise excluded from traditional Texan hospitals and clinics. Therefore, the purpose of this comprehensive literature review was to examine how prenatal care deliverance, and corresponding birth outcomes, could be improved for undocumented immigrants. Current methods of prenatal care were found to result in modest improvements in birth weight and increase in gestational ages; however, these increases were poor when applied to Mexican undocumented immigrant populations. Concurrently, it was found that anti-immigrant rhetoric and resulting fears of deportation may result in high levels of stress amongst the Mexican undocumented population. High stress from publicized nativist sociopolitical rhetoric was found to potentially lead to reductions in health seeking behaviors for Mexican undocumented immigrants, as well as reduce general physical health. A potential recourse for the negative effects of stress were explored in the formation of community bonds and conscious promotion of stress relief measures. Current tactics for health service towards Mexican undocumented immigrants was then examined and recommendations for increased social support groups and group prenatal sessions in FQHCs to increase post-birth neonatal health outcomes, were then provided.

Abstract Name: Revisit SHAP-based Explainable AI Framework for Multi-Class DDoS Attack Detection

Distributed Denial-of-Service (DDoS) is one of the major threats to computer networks. It can cause system users to temporarily lose access, or even for a prolonged period. Previous studies primarily focused on applied Machine Learning (ML) models such as Random Forest and K-Nearest Neighbors to address it. The focus of this research is to create an explainable AI system for detecting different forms of DDoS attacks, such as UDP Flood, SYN Flood, HTTP Flood, and so on, using advanced machine learning models and SHapley Additive exPlanations (SHAP) for interpretability. We aim to improve detection accuracy while providing transparency in model decisions. At first, the system was trained on the CSE-CIC-IDS2018 dataset (i.e., 500,000 network flows, 400,000 DDoS, and 100,000 benign) for binary classification, and XGBoost, LightGBM, and Neural Network models achieved accuracy and precision very close to 1. Even though these results were outstanding, binary detection does not show the complex nature of real-world attacks, which will often involve multiple DDoS variants. Later, we utilized multiclass detection using the ACI-IoT-2023 dataset (i.e., over 1,000,000 network flows). The methodology involved preprocessing network flows, feature engineering, and training SHAP-based models for multiclass classification. SHAP values were computed to provide feature-level explanations, enabling transparency, and aiding us in understanding model decisions, where consistently high importance of features are 'Fwd Pkt Len Mean', 'Init Fwd Win Byts', and 'Init Bwd Win Byts'. XGBoost achieved a model accuracy of 99.85%, with precision and F1 scores being 1 across nearly all attack classes, and LightGBM achieved an accuracy of 99.95% and precision and F1 scores being the same as the XGBoost model. Future work will focus on deploying the system in a cloud environment for real-time monitoring and scalability, reinforcing its practical relevance in securing IoT networks.

Abstract Name: Sustainability Orientation of Firms in Ghana and its Impact on Financial Performance

This study investigates the central research question: How does sustainability orientation, across environmental, social, and governance dimensions, affect the financial performance of firms listed on the Ghana Stock Exchange, and what role does regulatory compliance play in this relationship? Although sustainability has become integral to corporate strategy worldwide, scholarship on its financial implications in emerging markets remains limited, with existing findings often inconsistent due to uneven regulation, resource constraints, and varied interpretations of ESG practices. This project addresses these gaps by examining the Ghanaian context, where sustainability adoption is increasing but its strategic value is still debated. Guided by Institutional Theory, the study employs a quantitative research methodology using secondary data drawn from corporate annual reports, assessing firms' ESG orientations based on Global Reporting Initiative indicators alongside documented measures of financial performance. Partial Least Squares Structural Equation Modeling is applied to assess the relationships between sustainability orientation components, regulatory compliance, and financial performance. The analysis shows that environmental, social, and governance orientations each have a positive and significant effect on firm financial performance, with governance orientation emerging as the strongest predictor. Regulatory compliance is found to strengthen the relationship between environmental orientation and financial performance, while exerting minimal moderating influence on the social and governance dimensions. These results are discussed in relation to debates on ESG value creation in emerging markets and the role of institutional pressures in shaping corporate sustainability outcomes.

Abstract Name: THE INFLUENCE OF SOCIAL ISOLATION ON BLOOD PRESSURE IN YOUNG SEXUAL AND GENDER MINORITY ADULTS

BACKGROUND: Sexual and gender minority (SGM) adults experience more cardiovascular risk factors compared to their heterosexual cisgender counterparts. Social and cultural oppression exerts a weathering effect that contributes to cardiovascular health disparities. Evidence suggests that proximal minority stress is associated with the development of hypertension in SGM adults. However, limited information exists regarding proximal minority stress and blood pressure such as nocturnal dipping and morning surge in normotensive SGM adults. **METHODS:** SGM adults aged 19-30 (n=14, 79% female) participated in this 24-hour ambulatory blood pressure (ABP) monitoring study. Measurements were taken every 20 minutes during waking hours and 30 minutes during sleep. Nocturnal dipping was calculated as the ratio of average sleep to wake systolic and diastolic pressure. Morning surge was reported as the sleep trough, pre-awakening, and surge for systolic and diastolic pressure. Participants completed the Daily Heterosexist Experiences Questionnaire (DHEQ) to assess minority stress subscales including isolation, vigilance, and vicarious trauma. A median split used to group participants in low versus high minority stress. An independent t-test

was used to assess differences between low and high proximal minority stress. RESULTS: Isolation was the only proximal minority stress demonstrating significant differences in ABP measurements. Systolic morning sleep trough (11.86 ± 9.15 vs. 23.05 ± 9.93 mmHg, $p=0.049$) and pre-awakening systolic surge (7.14 ± 9.17 vs. 21.43 ± 10.03 mmHg, $p = 0.017$) were significantly higher in the high isolation group. This was observed in the absence of differences averaged systolic and diastolic blood pressure during waking and sleeping times. CONCLUSIONS: These data indicate that young SGM adults who report higher social isolation have a more pronounced morning surge, an indicator of cardiovascular risk often observed in hypertensive individuals. Future studies are needed to investigate strategies to improve blood pressure regulation through positive health behaviors, such as exercise.

Abstract Name: Flying Under the Radar: A Study of Adenovirus Prevalence and Genetic Variation in Oklahoma's Bat Populations

Bats carry more zoonotic viruses per species than any other mammal, making it necessary to identify the viruses' bats are carrying to track or prevent the spread of potentially harmful diseases. Mastadenovirus, a relatively stable adenovirus genus exclusive to mammals, is commonly found in many species of bats, making our goals of this study to estimate the frequency bats in Oklahoma carry adenovirus and compare their viral genetics to published viruses. Intestinal tissue was collected from 44 *Eptesicus fuscus*, 23 *Lasiurus borealis*, and 14 *Nycticeius humeralis* bats submitted for rabies testing in Oklahoma between 2023 and 2024. Of the 81 tested samples, a portion of the Adenoviridae DNA polymerase gene was successfully amplified in 14 *E. fuscus*, 5 *L. borealis*, and 3 *N. humeralis* samples respectively (27.1% positive). These samples were sequenced and compared to documented adenovirus sequences found on GenBank, followed by a phylogenetic analysis to study evolutionary relationships among our experimental samples. Analysis confirmed our samples create 3 distinct groups belonging to the Mastadenovirus genus: Group A containing 13 samples with identical amino acid sequences, most closely related to canine adenovirus found in *Eptesicus serotinus* (8% difference); Group B containing 8 samples with varying nucleotide sequences coding for identical amino sequences, most closely related to adenovirus found in *Nyctalus noctule* (11.4% difference); and Group C containing 1 unique sample, most closely related to adenovirus found in *Myotis ricketti* and an unclassified virus found in *Myotis yumanensis* (both 19.3% difference). The International Committee on Taxonomy of Viruses requires a 10-15% difference in amino acid sequence to designate a Mastadenovirus species, criteria that both groups B and C fit, warranting further investigation. This study is relevant to better understand how viruses are evolving, and its application can help identify how viruses become zoonotic and prevent further outbreaks across the nation.

Abstract Name: Application of the MiSeq FGx™ Next-Generation Sequencing System for the Deconvolution of DNA Mixtures in Simulated Sexual Assault Kits

Victims of sexual assault or rape may choose to have a sexual assault kit (SAK) collected to preserve any forensic evidence that remains on their person. Often, samples that are collected in these kits contain uneven mixtures of male and female DNA, with the female DNA being present in much higher quantities. These mixtures can complicate profile generation, especially if the male and female contributors have shared alleles in their profiles. Massively Parallel Sequencing (MPS) presents a potential alternative to DNA mixture testing, compared to the traditional Capillary Electrophoresis (CE) method. This research aims to utilize MPS to generate more robust DNA profiles that can be used for the identification of the male participant in contrived SAK samples. Continuing to explore and understand the use of MPS in relation to DNA mixtures could lead to a faster and more accurate method of mixture deconvolution and identification of the perpetrator's profile in relation to SAK testing. This could ultimately help to decrease the SAK backlog and give more victims justice. Various sample types will be collected to create two different contrived mixture types: known mixtures and casework-like mixtures. The known mixtures will be made with male and female buccal swabs that will be extracted and quantified before being combined in different ratios. The casework-like mixtures will be made by adding seminal fluid to vaginal swabs in varying dilutions. Each mixture type will undergo extraction, quantification, amplification, detection, and interpretation for both CE and MPS using appropriate kits and instruments. Data from both DNA methods will be compared. It is expected that MPS will produce data that is easier to interpret and more comprehensive than CE across all sample types.

Abstract Name: Past Skills, Future Paths: Integrating Research and Professional Development for History Majors

Undergraduate research courses provide avenues for the intentional cultivation of professionalism, mentorship, and community. The Franklin College History Department has revised its core research sequence of classes to include more robust integration of professional development that emphasizes connections between academic competencies and professional growth. We piloted a selective linking of the sophomore public history course and the senior research seminar this fall. Sessions on creating personal brands, online professional engagement, resume and cover letter writing, alumni networking, and vocational exploration all produced greater connectivity among our majors. While providing important models of professionalism for sophomores, seniors also inspired sophomores to envision themselves as scholars and researchers.

Simultaneously, sophomores challenged the seniors to reflect on and articulate their learning and experiences over the past four years, helping seniors connect their scholarship to their professional identity. Outcomes for this model included augmenting the professional development of seniors about to enter the workforce and sophomores seeking opportunities for internships and undergraduate research. Additionally, viewing the contrast between professional development in the sophomore and senior classes allows faculty to map student growth, assess teaching effectiveness, and provide individualized coaching to students. In this presentation, we will share the learning outcomes, successes and failures from this initial pilot, and plans for improvement in future iterations. This session will hopefully provide inspiration for mentors of undergraduate research who share our commitment to fostering a community of student-scholars who see their research as integral to their professional growth.

Abstract Name: PromptPilot: Ethical and Socratic Prompt Design for Human-AI Dialogue

Large-language-model (LLM) chatbots such as ChatGPT are reshaping education and everyday communication, but poorly framed prompts can unintentionally reinforce bias, escalate conflict, or generate emotionally unsafe content. The PromptPilot project explores how undergraduates can learn to design prompts that model empathy, clarity, and critical reasoning in human–AI dialogue. Drawing from frameworks in moral psychology and computer ethics—specifically Paul and Elder’s (2006) model of Socratic questioning, the APA Ethics Code (2017), and Schraw and Dennison’s (1994) theory of metacognitive awareness—this classroom-based pilot trained students to apply ethical and Socratic design principles when revising flawed AI prompts. This study builds on Costello et al. (2024), who demonstrated that GPT-4 can reduce conspiracy beliefs when it engages users in respectful, Socratic-style dialogue. Rather than relying on AI-generated responses, PromptPilot tests whether students can learn to prompt high-quality, empathetic dialogue themselves—positioning prompt design as a teachable ethical literacy skill. In this study, seven undergraduates (five from computing, two from psychology) revised a curated set of thirty flawed prompts about misinformation and emerging technology using structured Socratic tags ([C] Clarification, [A] Assumption, [E] Evidence, [R] Reflection, [Con] Consequences). Revised prompts were tested in GPT-4 conversations and scored using a binary rubric for tone (yes/no), logic (yes/no), and clarity (yes/no). Quantitative results showed that 100 percent of revised prompts produced respectful AI tone, 91 percent met Socratic logic criteria, and 86 percent encouraged reflective dialogue. Findings demonstrate that ethical prompting can be introduced and practiced as a metacognitive communication skill bridging psychology and computer science. By positioning students as “ethical designers” rather than passive AI users, the project reframes prompt engineering as a form of applied digital ethics. Future work will validate rubric reliability, expand sample size and prompt diversity, and integrate Natural-Language Processing metrics to assess semantic alignment and emotional balance.

Abstract Name: Assessing Psychological Safety in University Classrooms: Students' perceptions vs. instructors' behavior

Psychological Safety (PS)—one's perception of personal inclusion, contribution, and engagement—has been studied in various industrial settings but has yet to be studied systematically in educational settings. Initial research examined students' perceptions of PS in various college classes with a 51-question survey taken after the evaluated class had been completed. A total of 208 students completed that survey for various classes, and the findings of that initial study of PS suggested that both peer connections and classroom experiences were critical in determining students' average psychological safety (APS) scores. That survey included eight questions specific to APS that had been adapted from those previously used in industrial settings. However, it could not be determined if their APS scores were affected by a lack of recall or hindsight bias. This new study consists of two 8-question surveys distributed at the beginning and at the end of the semester to compare students' PS expectations with their PS experiences for the selected class. In addition, a behavioral check sheet will be completed in the class by undergraduate research students multiple times throughout the semester. This check sheet will record occurrences of behavioral predictors of PS and experiential learning to determine if aspects of each can be observed behaviorally. The predictors observed during class include professor and student interactions as well as the type of activities occurring during that class period. Classes of different topics, sizes, and modalities are being studied, but currently, most of the classes evaluated are taught through lectures with little interaction between the students and the instructor. It is expected that students' APS scores will be higher in classes with instructors who utilize experiential learning techniques and encourage student engagement.

Abstract Name: Exploring Parents' Journeys in Dyslexia Identification and Support

Dyslexia is a neurodevelopmental learning disability characterized by difficulties in decoding, single-word reading, and spelling. Early identification of dyslexia and timely reading interventions are essential for children with dyslexia. When support is delayed, students may struggle academically and psychologically, withdraw socially, or lose interest in school; which can affect graduation, future opportunities, and overall well-being. Parents are often the first to notice their children's reading difficulties. They observe their children individually, following their progress through assessment, tutoring, and interventions within and outside school, as well as witnessing their development, setbacks, and achievements. However, scant research has investigated parents' perspectives on their children's experiences with identification, assessment, and intervention around dyslexia, especially in the United States. Parents in prior studies have expressed frustration with barriers to school-based identification and greater satisfaction with support received from therapists or other interventionists outside of school. Past research has not examined factors that influence parents' satisfaction with school-based interventions to address reading difficulties; therefore, this aspect of the survey will be exploratory in nature. The study seeks to answer how parents of school-aged children with reading difficulties describe their experiences with identifying and meeting the academic, social-emotional,

and behavioral needs of their children. A survey was developed with mixed-method questions to gather information on the experiences, struggles, advances, and setbacks parents face when seeking support and services for their children with characteristics of dyslexia. This study hypothesizes that parents will report higher satisfaction levels when their child's reading difficulty is identified by their school sooner, and parents will report more positive emotions if they have access to any type of social-emotional support. The data will be analyzed through NVivo. Ultimately, the goal is to inform more effective, family-centered approaches to dyslexia identification, intervention, and support, within schools, family bonds, and through broader community networks.

Abstract Name: Preventing, Preparing, and Practicing for Active Shooter Events in Higher Education Institutions through Social Cognitive Theory and Mitroff's Management Model

Since the 1999 Columbine High School shooting, more than 394,000 students have experienced gun violence at school, a staggering indicator of how deeply mass shootings have affected the educational system (Cox, Rich, Trevor, Muyskens, & Ulmanu, 2025). While national attention often focuses on primary and secondary schools, recent tragedies, including the April 2025 shooting at Florida State University, underscore the vulnerability of colleges and universities. Active shooter incidents on college campuses continue to rise, yet a gap exists in the research on how campus community members perceive their own preparedness for responding to such an event. This phenomenological study explores how students, faculty, staff, and administrators at a private Southeastern university perceive prevention, preparation, and practice for the unlikely event of an active shooter situation. Guided by Bandura's (1977) Social Cognitive Theory, Mitroff's (2005) Crisis Management Model, and Witte's (1992) Extended Parallel Processing Model, the study focuses on the environmental, cognitive, and behavioral factors that shape an individual's self-efficacy and decision-making during an active shooter situation. Eight semi-structured focus groups will be conducted with 10 participants each. To reduce the influence of power differentials in the focus groups, two will be conducted with only students, two with only faculty members, two with only staff members, and two with only university provosts and deans. Participants will also complete pre- and post-surveys to assess shifts in perceived preparedness using the General Self-Efficacy Scale (1995). Preliminary findings suggest that participants value active shooter training but report varying levels of confidence in their ability to respond. Themes include uncertainty about institutional procedures, inconsistent exposure to training programs, and a desire for clearer communication and support from university leadership. This study aims to inform higher education administrators seeking to strengthen prevention, preparation, and practice initiatives for active shooter situations.

Abstract Name: New Indigenous Politics: The Role of Andean Indigenous Communities in Contemporary Peruvian Political Change

Indigenous communities across the Andean region have long been utilized by political leaders as a force for change, yet this has rarely manifested in meaningful political incorporation. Over the past two decades, however, countries like Bolivia and Ecuador have seen increasing indigenous participation within formal political institutions, exemplified by the rise of Evo Morales's Movimiento al Socialismo (MAS) party and Ecuador's Pachakutik movement. Unlike the other Andean nations, this phenomena would not be seen in Peru, who remained an outlier throughout the 2000s and 2010s, where indigenous political participation remained both disconnected and unable to generate national political power. This trend shifted dramatically with the 2021 election of Pedro Castillo, whose unexpected victory reflected unprecedented indigenous and rural mobilization. This study argues that the delayed nature of Peruvian indigenous political participation (in comparison to the other Andean nations) was a result of: [1] the corruption of the Peruvian state, [2] the dominance of the Fujimori family since the start of the 1990s, and [3] a long history of state violence against indigenous communities: from early colonial repression to modern military massacres; as well as third party violence, such as the internal conflict with the Sendero Luminoso guerilla group. This study also posits theories as to how this mobilization has come about in contemporary Peru, and the potential implications for the future of indigenous politics in Peru.

Abstract Name: "They Say I Won't Last Too Long on Broadway:" The State of African American Representation within University-Level Theatre Arts Programs

Contemporary Black representation exists within the ebbs and flows of cultural trends. Throughout different periods, the quantity of Black people featured within entertainment and the quality of roles available for Black entertainers have fluctuated wildly. In an entertainment-focused society, the role of performance becomes increasingly important as a means for societal influence. The most visible and commonly accessible mediums for artistic influence are those that rely heavily on the talents and skill sets built upon within university programs for theatre arts. The histories of the theatre, film, and television industries are marked with deep disenfranchisement, misrepresentation, and the absence of Black perspectives. This (mis)representation (or lack thereof), in turn, contributes to a continuation of societal stereotyping, mistreatment, and structurally racist ideals, which work for the mass disempowerment of African Americans. Only through gaining insight into the current state of collegiate-level educational practices for theatre arts students can the effect and depth of racially charged factors inhibiting effective Black representation in the United States be investigated, and eventually rectified. To what extent are Black university students underrepresented within theatre arts programs as compared to other students, and what consequences does this underrepresentation have for their participation and influence as Black creatives within media at large, like television, film, and theatre? Our research intends to show the lack of positive Black representation in these programs contributes to industry-wide disenfranchisement, a stagnation in healthy portrayals, and a cultural perception of African American inadequacy.

Abstract Name: The planarian Hox gene post2b limits body size and preserves allometry

The molecular and cellular basis by which the size and patterning of body forms across the tree of life is the fundamental focus of developmental biology. However, the mechanisms by which body plan allometry —the scaling between the size of a body and its parts —is still poorly understood. I utilized the planarian species *Schmidtea mediterranea* (Smed), a flatworm capable of regenerating its entire body form from a small piece. We identified the Hox gene post2b as a restrictor of planarian body size, and genetic interference of post2b enables animals to grow more than six times their natural size limit. This presents a unique opportunity to study the interrelationship between changes in the size of a body and its parts. Through brightfield imaging and morphometric analysis, we resolved the differences in whole-body and photoreceptor region, axes, and growth/degrowth in normal Smed and post2b RNAi animals. Our findings support a model in which the growth differentials of body parts are either maintained or exaggerated as size is delimited. Studying developmental allometric signaling processes in this simple model can provide a better understanding of the shared pathways that regulate differential tissue and organ growth potentials underlying human development and disease.

Abstract Name: Investigation of Transcutaneous Spinal Cord Stimulation in Evoking Upper Extremity Muscle Response in Stroke Survivors

An estimated 795,000 people in the United States annually experience stroke. Up to 80% of stroke survivors have resulting upper extremity (UE) impairment; UE impairment results from a reduced corticospinal excitability, which significantly impairs the brain's ability to activate arm/hand muscles, leading to chronic, moderate-to-severe UE impairments. Stroke patients experience significant quality of life reduction with impaired UE function, including inability to self-finance, participate in social activities, and loss of independence in daily tasks. The corticospinal tract is a critical pathway for conveying motor commands from the brain to the spinal cord, enabling voluntary movement of the UEs. Little is known about the integrity of the connections between the spinal cord and UE muscles after stroke. Electrical stimulation of the spinal cord could potentially offer a means to increase motor signals from the brain reaching the UE muscles. Therefore, the study of minimal threshold for muscular response and the latency from electrical stimulus to muscular response in stroke survivors could reveal mechanisms previously not targeted for treatment. Several novel rehabilitation interventions have been developed based on this principle to improve UE function after stroke, including non-invasive brain stimulation (NIBS). NIBS, currently the focus of stroke rehabilitation, aims to increase plasticity and improve UE function through electrical stimulation of the brain, but the propagation of the signal through the tract is not easily assessed. Non-invasive spinal cord stimulation, often termed transcutaneous spinal cord stimulation (tSCS) is a prospective treatment offering a safer, inexpensive, and non-invasive method of stimulating the UE pathway, ensuring the integrity of connections between spinal cord and UE muscles. This investigation aims to measure the reliability of muscular evoked responses while delivering tSCS to stroke survivors, as a preemptive investigation, to establish tSCS as a treatment method with task practice to improve long-term outcomes post stroke.

Abstract Name: Project Chimaera: Development of a Tessellated Tetrahedral Truss Structure for Adaptive Multi-Regime Morphing Wing Technology

Modern aircraft aerodynamic efficiency is currently limited by fixed-wing geometries designed for a single optimal flight regime. This has resulted in compromised performance due to the various maneuvers and speeds aircraft utilize during flights. This limitation is addressed by developing scalable modules of tessellated tetrahedron truss structures capable of dynamic structural reconfiguration, resulting in small surface deformations across the wing. This morphing wing is contrary to traditional wings since this design can modify the wing's planform, altering sweep, twist, span, and airfoil cross-section through the extension and retraction of internal feedback linear actuators. Additionally, this morphing-wing design will enable aircraft to go between subsonic, supersonic, and hypersonic speeds due to the alteration of the wing geometry during flight. The research methodology integrates kinematic and dynamic modeling in CATIA and MATLAB, along with physical prototyping to produce a morphing wing. A physical structure allowing for movement within the internal wing structure has been designed. This model wing is currently in the manufacturing stage of research. The wing's electrical design, along with the control logic, is being analyzed and validated to confirm that the linear actuators can communicate and alter their movement to different linear positions. The study anticipates demonstrating a fully functional prototype capable of controlled morphing. The study proposes that this internal design for morphing wing technology is a viable pathway for the next generation of aircraft, allowing for increased aerodynamic efficiency and capabilities of multi-regime flight. This morphing technology will create a more viable option to utilize aircraft at higher speeds, such as supersonic and hypersonic speeds, making high-speed travel more feasible within aviation.

Abstract Name: Math Learning Difficulties in Primary Grades and Effective Intervention Strategies

The goal of our study was to examine the math learning difficulties of primary grade children. Specifically, our two objectives were to identify the math difficulties of students and to determine supportive teaching strategies. Previous research has analyzed developmental math and specific learning disorders regarding math, but there is minimal research about what falls in between: math difficulties. This study collected survey data from elementary school teachers and interventionists (n=42), gathering quantitative and qualitative data on difficulties and interventions. The survey included 8 demographic questions, 23 Likert scale questions on math behaviors, 3 multiple response questions, and 5 open ended questions. Specifically, the questions pertained to frequency of difficulties within math behaviors, access to training, and strategies to support math

skills. Math difficulties were categorized by 1) number sense and computation, 2) geometry and measurement, 3) patterns, algebra and data analysis, and 4) general math behaviors. Findings indicated that number sense and computation difficulties were the most common, followed by difficulties with patterns, algebra and data analysis. Teachers reported that they lacked formal training in identifying and supporting math difficulties. Teachers felt they had a lack of time, resources, staff, and space to provide support to students who struggle with math while also staying on pace with curriculum. Teachers recognized that online programs may not be sufficient in remediating the difficulty and may only be beneficial for progress monitoring. Future research needs to identify effective training and strategies for supporting students with math difficulties. Further, online programs should be developed that not only help with progress monitoring but can also act as an intervention to promote math skills.

Abstract Name: Examining Predator and Round Goby (*Neogobius melanostomus*) Response to Varying Eyespot Positions in Round Goby

The round goby (*Neogobius melanostomus*) is an invasive species that was first caught in Lake Erie in 1994 and has been increasing in population size ever since. Gobies negatively impact the ecological integrity of Lake Erie by out-competing native benthic fish and consuming the fry and eggs of lake trout (*Salvelinus namaycush*) and smallmouth bass (*Micropterus dolomieu*). Part of the round goby's success in Lake Erie is due to the reduced predation pressure they experience here relative to their native range. This reduction in predation risk may be aided by their eyespots—markings that mimic the eyes of a larger vertebrate predator. According to a recent study done by Penn State Behrend, round goby caught in the main waters of Lake Erie were more likely to have eyespots on their dorsal fin, while individuals caught in the tributaries were more likely to have pectoral eyespots. The objective of this study is to determine how potential native goby predators (i.e., smallmouth bass, rock bass (*Ambloplites rupestris*), freshwater drum (*Aplodinotus grunniens*), and yellow perch (*Perca flavescens*)) and other round gobies in Lake Erie respond to round goby's eyespots on their dorsal and pectoral fins. To test this, round goby models with different eyespot positions were made and attached to an underwater camera to examine the predators' and round gobies' attack and avoidance responses. Once data analysis is complete, we will be able to better understand the mechanisms enabling round goby success in Lake Erie.

Abstract Name: The Impact of Parental Limited English Proficiency (LEP) on U.S.-Born Latin American Children

The specific challenges faced by U.S.-born children of Latin American immigrant parents with limited English proficiency (LEP) remain understudied. One such challenge is the role that these children often assume as an English interpreter for their parents. Although prior research has examined the consequences of LEP on adults, it is equally critical to understand how their English-speaking children are impacted. This

literature review synthesizes current research on how Latin American parental LEP affects the physical, mental, and academic outcomes of children who are the sole English speaker in their household, and the unique burdens they carry. This review includes studies that examine overall language proficiency in immigrant households, community involvement of immigrant families, healthcare access and utilization, school engagement among immigrant children, and acculturation stressors these children face. The main trends across the literature reveal that the responsibility of acting as a linguistic broker creates mental, physical, and academic obstacles that are not typically found in children of English-speaking households. As children of immigrant families continue to represent a quickly growing proportion of the U.S. population, these studies are increasingly relevant. The goal of this review is to illuminate the ways in which parental LEP shapes child well-being and to emphasize the need for targeted supports that can improve outcomes for these children.

Abstract Name: Persistent increase in mechanical pain sensitivity in mice following formalin injection: novel neuropathic pain animal model

Neuropathic pain is a chronic pain condition resulting from nervous system damage, characterized by hyperalgesia and allodynia. While inflammatory pain can be resolved with medications, neuropathic pain does not respond to current pharmacological treatments, creating a significant clinical concern. Rodent models are commonly used to study pain mechanisms. Formalin is used in the context of inflammatory pain research as a chemical irritant, inducing tissue injury and producing reproducible pain-related behaviors. Previous research in rats demonstrated that formalin injections can induce chronic pain states and molecular changes within the spinal cord comparable to those of spinal nerve ligation, an established surgical model of neuropathic pain. This study aimed to determine whether a subcutaneous injection of 5% formalin is sufficient to induce chronic pain in mice, providing a simple and less invasive model to study chronic pain mechanisms. Because pain cannot be directly measured in rodents, behavioral assessments are used to quantify “pain-like” behavior. Mechanical pain sensitivity is assessed using the von Frey filament test, in which a series of calibrated filaments is applied in ascending order of force to the plantar surface of the paw, and the withdrawal threshold is recorded as an indicator of mechanical sensitivity. Reduced thresholds indicate heightened pain sensitivity. Mice were tested on days 3, 7, 10, and 14 post-injection and terminated on the day of the last observation. Brains and spinal cords were collected for histology to determine molecular and cellular changes. Mice receiving formalin exhibited a significantly lower withdrawal threshold compared to the vehicle-treated group, indicating heightened mechanical sensitivity and suggesting the development of chronic formalin-induced hyperalgesia. These findings suggest that a single subcutaneous injection of 5% formalin provides a reproducible, less invasive method to study chronic pain in mice. Further studies are necessary to define long-term molecular and cellular changes in the nervous system.

Abstract Name: The Cycle Within the Game: How Hormones Shape Mobility and Lower Limb Injury Risk in Female Athletes

Female athletes sustain up to a ten fold increase in musculoskeletal injuries compared to males, with ACL tears being one of the most common injuries (Raj et al.,2023). The menstrual cycle is associated with cyclic changes in the hormones proestrogen and estrogen, which could have an impact on mobility of the knees and hips in female athletes. This study directly assesses changes in both joint mobility and hormone levels in female collegiate athletes in an attempt to determine increased risk of injury associated with different phases of the menstrual cycle. Under an approved IRB protocol, consenting participants were asked to complete a physical and menstrual health background survey and then track their menstrual cycle daily for 3 months in a provided form. Participants were also asked to provide saliva samples and undergo knee and hip measurements via goniometer on days 3, 13, 22, 23, and 24 of each cycle. Bilateral joint measurements were taken in the supine (knee and hip) and prone (only knee) positions included flexion (knee and hip) and abduction (hip only). Following data collection, saliva samples will be assessed via ELISA assays for estrogen and progesterone levels. Data will be analyzed for correlations between changes in joint mobility and fluctuations in hormone levels over the course of the menstrual cycle. Findings could lead to better predictions of when a female is at an increased risk of injury during their cycle and could lead to adjustments in training programs to better decrease the incidence of injury in female athletes over males.

Abstract Name: Evaluating the Efficacy of the Search, Treat, and Prevent Model: A Comprehensive Approach to Tuberculosis Eradication

Tuberculosis (TB) remains the world's leading infectious disease killer, disproportionately affecting marginalized communities despite the availability of effective treatment for decades. Global progress toward TB elimination has stalled, particularly in low- and middle-income countries where socioeconomic instability, stigma, and limited healthcare infrastructure hinder early detection and treatment adherence. The COVID-19 pandemic further reversed years of progress, exacerbating resource shortages and widening global health disparities. To address these challenges, this study evaluates the efficacy and sustainability of the Search, Treat, and Prevent (STP) model—an emerging, proactive approach that expands upon Directly Observed Therapy (DOT) by integrating active case finding, patient-centered treatment support, and preventive therapy for latent TB infection. Using a mixed-methods cross-sectional design, this project analyzes TB infection trends, treatment success rates, and treatment barriers across the United States, Kenya, and Peru. Primary data collection will include the administration of the WHO-validated Knowledge, Attitudes, and Practices (KAP) survey to clinicians at partnering health facilities, documenting their perceptions of current treatment models, adherence challenges, and resource limitations. Additionally, in-depth qualitative interviews will be conducted with selected healthcare professionals—including clinicians from the United States involved in TB diagnosis and treatment, *Socios en Salud* in Lima, and hospitals and clinics in western Kenya—to explore systemic factors influencing TB care, implementation challenges, and the practicality of the STP model in resource-limited settings. The project will culminate in a documentary film and academic manuscript, with the overarching goal of advancing equitable standards of TB care and reducing global TB mortality.

Authors:

Abstract Name: Visual Silence: Art Censorship in the Viceroyalty of Peru, the Onganía Regime, and Nazi Germany

This research examines art censorship in 1600s Viceroyalty of Peru (later becoming Argentina) and in Nazi Germany. The examination will begin with a discussion of art censorship in the respective societies. Then, the study will analyze how the Spanish Inquisition censored the indigenous culture of the Viceroyalty of Peru by examining the artwork of Guaman Poma, a Quechua nobleman, who denounced this mistreatment of the native Andean people with his drawings from 'The First New Chronicle and Good Government'. Following, the discussion will introduce Argentina under its dictatorship of General Carlos Onganía from the 1960s to the 1970s, and examine the work done by the Tucumán Arde in communicating opposition of the dictatorship. Next, the study will discuss how the art group Die Brücke was targeted by the Nazi's 'degenerate art' campaign. The comparative conclusion demonstrates that in either case, censorship was used to support the power structure, but in different ways. Viceroyalty of Peru used censorship to maintain religious catholic orthodoxy, Argentina targeted the art that opposed the government, while Nazi Germany used art censorship to create a new 'cultural agenda'.

Abstract Name: Exploring Campus Sexual Assault Through Photovoice

This study explores how students perceive campus safety within the broader context of campus sexual assault. While much research focuses on the prevalence of sexual assault, prevention programs, and Title IX compliance, less attention has been given to how students interpret safety in the environments they inhabit. This project addresses that gap by centering on student perspectives and examining the factors that influence whether they feel secure or vulnerable on campus. Thus, the central research question asks: What protective and risky cues shape students' sense of safety on a college campus, and how do these perceptions compare to institutional narratives about safety and support? Using Photovoice, three University of Kentucky students photographed spaces and features on campus that made them feel either safe or unsafe. Participants collected eleven photos and provided short captions describing their interpretations. These photos and reflections were analyzed thematically to identify patterns in how students understand campus safety and how their experiences align, or fail to align, with institutional messaging around sexual misconduct resources and prevention. Three themes emerged: visibility and environmental design, community and familiarity, and institutional presence and trust. Students highlighted well-lit, open, and maintained areas as places that increased their comfort, while darker or isolated spaces evoked unease. Familiar academic settings provided reassurance, showing how routine and belonging contribute to a sense of safety. Institutional features such as security cameras and emergency towers were interpreted in mixed ways, signaling protection and doubt depending on their functionality. Notably, no participant photographed formal campus resources related to sexual misconduct, suggesting a disconnect between institutional infrastructure and students' lived experiences. Overall, the project shows that student perceptions of safety are shaped by environment, routine, and institutional trust and play an important role in understanding how campus communities experience issues tied to sexual assault and campus security.

Abstract Name: Flavonoids as a novel therapeutic strategy for luminal androgen receptor triple negative breast cancer

Breast cancer remains a leading cause of mortality among women, affecting approximately one in eight over their lifetime. Triple-negative breast cancer (TNBC), a particularly aggressive subtype, lacks expression of estrogen, progesterone, and HER2 receptors thereby rendering most targeted therapies ineffective. As a result, there is an urgent need for novel treatment strategies. One distinct TNBC subtype, Luminal Androgen Receptor (LAR) breast cancer, expresses the androgen receptor (AR). Previous work from our lab and others has demonstrated that AR interacts with GLI3, a key transcription factor in the Sonic Hedgehog (SHH) signaling pathway, to promote tumorigenesis in androgen-independent prostate cancer. Notably, clinical data reveal that patients with LAR TNBC and elevated GLI3 expression exhibit poorer prognoses, a correlation not observed in other TNBC subtypes. We thus hypothesize that GLI3-mediated SHH signaling is aberrantly activated in LAR TNBC via its interaction with AR, and that targeting GLI3 will offer a subtype-specific therapeutic approach. To investigate this, we performed quantitative PCR on LAR TNBC cells, confirming upregulation of GLI3 target genes in these cells. Next, we performed MTT screening assays to identify novel therapeutic compounds capable of selectively targeting TNBC LAR cells. This study focused specifically on flavonoids, a class of compounds known for their broad anti-cancer properties. Through our screening efforts, we identified several flavonoids that selectively inhibit LAR TNBC cell growth and, importantly, that treatment with these compounds leads to a reduction in GLI3 signaling. These findings thus highlight a promising avenue for the development of targeted therapies for the LAR subtype of TNBC by targeting the GLI3 signaling pathway with flavonoid compounds.

Abstract Name: A New Approach to Mystery Snail Collection: Bait Preferences in Passive Sampling as a Control Strategy

The Chinese mystery snail (*Cipangopaludina chinensis*) is an invasive freshwater gastropod that has established itself across North America, posing a threat to native aquatic ecosystems, including Lake Erie's Presque Isle State Park. Traditional active sampling methods for mystery snail populations are labor-intensive and ineffective, particularly in deep or turbid waters. However, the efficacy of passive sampling (i.e., trapping) has not been extensively researched. My study investigated passive sampling as a potential alternative for capturing mystery snails and aimed to determine whether the type of bait affects capture success. Field

experiments were conducted from June to August 2025 at Presque Isle State Park, Pennsylvania, using modified cylinder traps with five bait types: moist cat food, cucumbers, algae pellets, boiled spinach, and an unbaited control. Traps were set up at five locations: Feather Point, Lily Pond, The Bridge, Graveyard Pond, and Thompson Bay. Across trials, the average snail captures were low, with algae having the highest mean (0.083 snails/trap), followed by moist cat food (0.042), boiled spinach (0.042), control (0.042), and cucumber (0.028). These results suggest that bait type had little effect on snail capture, potentially because the baits were not strong enough, the traps were not left in the water long enough, or because the snails preferred different food sources. Despite low capture rates, passive sampling was able to capture snails, indicating that it may be a useful method for monitoring snail populations. Testing more aromatic baits and using alternative trap designs could improve capture efficiency and inform future sampling strategies.

Abstract Name: Evaluating Fog Liquid Water Content Through Capacitive Sensing to Assess Fog Harvesting Potential

Fog water harvesting has emerged as a potential supplementary water source for communities facing increasing water scarcity, yet its reliability depends heavily on the amount of liquid water present in fog events. Current fog-collection systems mainly rely on passive mesh structures and do not directly measure fog liquid water content (LWC), making it difficult to predict water yield or assess long-term productivity. This project investigates whether capacitive sensing can be used as a practical method to quantify the LWC of fog, with the broader goal of determining whether fog harvesting can serve as a sustainable water resource in water-limited regions. The experimental design consists of a parallel plate capacitor with polypropylene filter material as the dielectric. As air is drawn through the capacitive sensor, fog droplets accumulate on the filter material, increasing its capacitance. By monitoring the change in capacitance over time, LWC can be derived. Background research on fog formation, droplet behavior, and moisture-responsive sensing technologies provides the foundation for exploring this approach. Over the course of the project, relative humidity tests revealed slight increases in measured capacitance, suggesting that ambient moisture influences the sensor more than expected. Additional tests using incremental droplet deposition, simulating fog collecting on a surface, produced consistent and measurable increases in capacitance, demonstrating that the system is highly responsive to changes in surface water content. By analyzing these trends, this study aims to determine whether capacitance data can be reliably correlated to fog LWC and, ultimately, to the volume of water that could be harvested during fog events. If successful, this approach could offer a low-cost, low-energy tool for evaluating fog density and predicting water yield, supporting efforts to develop sustainable fog-harvesting technologies for regions experiencing chronic water shortages.

Abstract Name: JayWing Academy: An AI-Powered Student Learning System Leveraging GPT in Cloud

Over the past few years, Large Language Models (LLM) such as ChatGPT, Gemini, and Claude have become widely used tools for academic assistance in college settings. However, students frequently use these tools as shortcuts for quick answers, rather than as supports for meaningful learning. While LLMs offer insights based on extensive training data, they often fail to align with the instructor's pedagogical learning path and lack the interactive guidance provided by human tutors. This project asks how AI tutors can support deeper learning with JayBot, a college-level AI Tutor that generates responses grounded in course-specific materials uploaded by instructors. Research results show that reliant LLM users show lower brain engagement and perform below other people in their ability to analyze information. However, using it as a tool to revise work showed positive results and improved the users work drastically. JayBot aims to emulate the conversational, reasoning-based guidance of human tutors that promotes student learning as a scholarly assistant. To return responses from JayBot that encourage critical thinking from students, the project employs retrieval-augmented generation (RAG) and few shot prompting. RAG is a technique that grounds responses in instructor-provided materials by retrieving external documents and few shot prompting helps prevent instructional dilution, where prompt instructions for JayBot are lost. These methods help students work through problems with a socratic questioning approach instead of immediately providing answers. Experiments in computer science courses show that JayBot enhances instructional alignment by reducing premature exposure to advanced topics, limiting solution over-disclosure, and preserving pedagogical intent.

Abstract Name: Women, Tradition, and Cosmopolitanism in Mira Nair's Monsoon Wedding

This research analyzes how Mira Nair's film *Monsoon Wedding* (2001) portrays women's agency within the setting of a wealthy Indian family preparing for a large, traditional Punjabi wedding in a globalizing India. The film follows several intertwined storylines during the days leading up to the ceremony, and this research focuses on how two central characters, Aditi and Ria, navigate the tension between long-standing cultural expectations and the influence of global, modern values. Aditi struggles with the pressure to uphold family honor while also trying to define her own desires, and her choice to proceed with an arranged marriage reveals how tradition can shift when supported by class privilege. Ria's story confronts a different barrier when she chooses to speak about past sexual abuse in order to protect a younger cousin. Although her courage challenges patriarchal silence within the household, the film ultimately contains her resistance within the authority of the family patriarch. By comparing these women's experiences with those of working-class characters whose lives exist outside the comforts of the Verma family home, this project also analyzes the links between female empowerment and class position. Overall, this project argues that *Monsoon Wedding* reflects a broader moment in India where globalization influences women's lives, yet traditional structures adjust themselves in ways that allow the upper middle class family to stay intact rather than be transformed.

Abstract Name: No Rhymes With A Reason: Defining Abstract Hip Hop

This research seeks to define and analyze abstract hip hop and its stylistic characteristics as a counter-culture

movement within hip hop. Formal research addressing abstract hip hop as a stylistical movement is lacking. Research on abstract hip hop has been explored with Pil Ho Kim and Wonseok Lee, while horror-core, an abstract hip hop adjacent style, has been analyzed by Dana Horton in *Global Hip Hop Studies*. How historically non-white styles of music are studied have brought into question social and methodological connotations of music analysis. This was a prominent point in “Music Theory and the White Racial Frame” by music theorist Phillip Ewell, influencing the methodology of this research. Other scholars like Kofi Agawu and his use of hermeneutic analysis equally informed the prime approach used for primary source analysis. The case studies “Sheesh” by Homebody Sandman and “Hacker” by Death Grips are interpreted through three main analyses: metric, syllabic, and literary, proving how abstract hip hop artists set themselves apart from mainstream rappers. Metric analysis takes place in transcribing the instrumental or “beat” and interpreting what artistic message may be conveyed. Syllabic analysis, akin to poetry, takes the stressed and unstressed syllables of the rapper’s lyrical excerpts and analyzes them through interpretation. Literary analysis takes lyrics or other direct artistic choices (outside of syllabic or metric) and uses hermeneutics as a form of analysis. Through these case study analyses, techniques like rhythmic subversion, cosmic braggadocio, unorthodox samples, generative flow, prominent use of micro time, and metric obscurity are identified. Themes of distance from this counter-culture in terms of sound, presentation, and language are known and defineable, separating this specific style from hip hop. In other words, abstracting it.

Abstract Name: The Effects of Natural Products and Food Additives on Lysosome Function

Gastric disorders, such as gastroesophageal reflux disease (GERD) affect at least 20% of the United States population. The most common pharmacological intervention is the use of Proton Pump Inhibitors (PPIs). These drugs are converted into their active forms upon entry into acidic environments, and while their intended function is to inhibit parietal proton pumps in the stomach and reduce gastric acid secretion, there may be off-target effects in other areas with low pH, such as lysosomes. These organelles mediate the recycling and degradation of cellular materials. The current research seeks to examine the effect of PPIs on lysosomal function. Previous scientific studies have shown that PPIs such as lansoprazole and omeprazole can inhibit lysosomal enzyme activity. Decreased lysosomal activity has been implicated in impaired immune function and the development of neurodegenerative disorders including Alzheimer’s disease, amyotrophic lateral sclerosis (ALS), and other diseases. Preliminary experimental results demonstrate the successful isolation of active lysosomes from multiple murine tissue types including brain, liver, lung, kidney, and spleen. Lysosomes were also extracted from cultured cell lines, specifically COS-1 cells derived from monkey kidneys. These lysosomal fractions were obtained via differential centrifugation, and their activity was confirmed using an acid phosphatase assay, the standard method for assessing lysosomal function. Finally, COS-1 cells were treated with PPIs, and the lysosome activity was measured, clearly demonstrating altered enzymatic function due to the presence of the PPI. Future experiments will extend this analysis by testing the effects of PPIs on another lysosomal enzyme, β -N-acetylglucosaminidase (β -NAG), and on other cell lines, such as Caco-2 and A549 cells. This experimental procedure also allowed for the examination of the effects of additional compounds, including natural products and food additives, on proton pumps and overall lysosomal function.

Abstract Name: Case Study of Sewing Joinery Technique

For over 20,000 years, sewing has been a vital joinery technique. In the beginning stages, people used animal sinew for thread and bones or horns as needles. What started as a technique that is done by hand, has greatly evolved and is now mainly taken over by a simple machine. In these designs, the cross stitch sewing method is predominantly used to show joinery and texture within the space or artifact. This study examines the sewing joinery technique to determine how it can be applied at multiple scales in interior design so that it can be diagrammatically and visually documented on this research poster. For this research, the joinery has been studied at increasing spatial scales from a small artifact level to enclosure, personal, and social spaces. The research shows sewing, a commonly used joinery technique that uses a needle and thread to interlock things together. This method closely relates to the interlocking spatial relationship, because it forces two spaces to come together and perform as one cohesive space. The plans of personal and social spaces show the same interlocking relationship through the arrangement of walls and the circulation pattern. In conclusion, after researching and learning about sewing as a joinery, sewing can be used in a small joinery scale as well as in a larger spatial scale. Analyzing the cross-stitch thread patterns helps easily translate this joinery into interior design spaces to help display spatial relationships in design.

Abstract Name: Project 2025 and the Politics of Fear: How Far Right Organizations Use Emotional Appeals to Consolidate Power

In recent decades, particularly under the Trump administration, there has been significant debate over the constitutionality of the actions taken by conservative groups. This paper aims to examine how conservative political actors have intentionally mobilized public support through fear-based and morally charged rhetoric with the intention of exploiting social divisions around race and gender. Drawing on journal articles informed by policy, psychology, and case studies, the paper analyzes how conservative movements cultivate racial resentment, reinforce traditional gender roles, and appeal to religious and national sentiment. These groups have created a political environment where the conservative populace are especially and increasingly susceptible to emotional manipulation. As a result, this susceptibility, alongside ideological polarization and the strategic breaking down of democratic integrity has allowed conservative movements to reshape American democracy in their interests, leading the way for the consolidation of authoritarian power layered under the guise of moral and national restoration. Understanding these dynamics is critical for recognizing how identity-based rhetoric and strategic polarization function to erode citizens' capacity for informed democratic participation and operate as mechanisms for restructuring democratic norms and institutions.

Abstract Name: Solving Sudoku with Quantum Annealing: A QUBO Formulation Approach

Sudoku encodes constraint satisfaction structures underlying real-world scheduling, logistics, and resource allocation problems, making it an ideal benchmark for evaluating quantum optimization against classical methods. We investigate whether quantum computing delivers practical advantages for this class of combinatorial problems. We developed a one-hot encoded QUBO formulation mapping Sudoku constraints into energy penalties compatible with quantum annealing hardware. Each cell-digit assignment becomes a binary variable in a Hamiltonian where valid solutions achieve zero energy. We tested this approach using classical simulated annealing and QAOA across 2×2 to 9×9 grids. Classical simulated annealing achieved 99% success on 4×4 puzzles and 10% on 9×9 instances (459 variables after incorporating givens). QAOA demonstrated proof-of-concept on 2×2 instances but hit exponential memory limits beyond 8 qubits, confirming current gate-based quantum approaches cannot scale to practical sizes. Our QUBO formulation directly targets quantum annealing architectures like D-Wave, where dense constraint handling may reveal computational advantages. Future work will benchmark this formulation on D-Wave hardware. This work establishes methodology and baseline metrics for determining when quantum optimization surpasses classical methods for structured combinatorial problems with real-world applications.

Abstract Name: Narratives of Calling: Catholic Sisters on Culture, Community, and Continuity

The number of Catholic Nuns within the United States has dropped by 72% between 1965 to 2014. Although the number of men entering religious life has recently increased, the number of women entering religious life has continued to decline to less than 150 in 2024. Amid these trends, many nuns have voiced concern about attracting women to religious life. Catholic nuns have long dedicated their lives to the service of their communities as nurses, teachers, social workers, and spiritual leaders. These vocational contributions have had a profound impact on their communities. Despite their continued presence in ministries across the country, there is limited research exploring how the sisters themselves understand and approach the modern challenges of recruitment, retention, and talent development for this unique vocation. This research aims to explore the current recruitment strategies, development opportunities, and benefits of nunship largely unknown by the general population. With concerns of declining interest in nunship in America, it is important to identify current barriers and explore possible solutions. This research follows my thesis work with semi-structured interviews with Catholic nuns as they identify the culture of the convent and give their perspectives on the future of nunship in America. These interviews will be interpreted through reflective thematic analysis to identify themes and patterns between the participants' interviews. Based on participant responses, I will offer recommendations to support Catholic sisters and shape future recruitment strategies that are responsive to the realities of religious life today.

Abstract Name: Characterizing Individualized Maximal Power-Cadence Relationships at Various Fatigue Levels for Recreational Cyclists

Human performance during exercise reflects the delicate balance between energy availability, fatigue, and recovery. Understanding this balance is key to optimizing training, enhancing race performance, and preventing overexertion. Our long-term goal is to create individualized models of fatigue and recovery that predict an athlete's power output as a function of time, cadence, and prior exertion. Such models could ultimately guide adaptive training programs and personalized pacing strategies for both recreational and competitive cyclists. This study examines one element of that model: how fatigue affects the well-known parabolic relationship between maximal cycling power and pedaling cadence. Four recreational cyclists completed six testing sessions, each separated by at least one week for full recovery. The first four sessions determined each participant's Critical Power (CP) and Anaerobic Work Capacity (AWC) by fitting a hyperbolic relationship between sustained power and endurance time. The final sessions assessed maximal power and cadence at different fatigue levels. Fatigue was induced in stages by cycling for two minutes at each subject's CP8 (the power expected to cause exhaustion in eight minutes), followed by five sprints at varying resistances to establish the power-cadence curve for that fatigue level. Paired t-tests compared results between fresh and fatigued states, with significance set at $p < 0.05$. Across all participants, the power-cadence relationship remained parabolic, with coefficients of determination (R^2) above 0.9, indicating excellent fits. Fatigue significantly reduced maximal cadence ($p = 0.039$) and cadence at maximal power ($p = 0.039$) but did not significantly affect maximal power ($p = 0.101$). These findings show that fatigue predictably alters the shape of the individual power-cadence curve. This work represents progress toward data-driven, individualized fatigue and recovery models to guide intelligent training and pacing strategies.

Abstract Name: A.I. Chatbots and the Tradition of the American Technological Sublime

This study explores how particular individuals in the contemporary United States interpret their frequent interactions with artificially-intelligent Social Chatbots as a Sublime experience. I define "Sublimity" in relation to emergent communication technologies using the combination of frameworks developed by Rudolph Otto, Keltner and Haidt, David E. Nye, James Carey and John Quirk. Drawing on a variety of case studies documented by scholars, researchers and journalists (as well as the self-reported), I examine the ways in which these contemporary encounters are described and received by the general public, and compare this to related case studies of the eighteenth through the early-twentieth centuries. Importantly, I focus on similar cultural patterns that emerge: the phenomenon of the American Technological Sublime, increased public concern about the users' mental health and possible disassociation from reality, the anthropomorphizing of media technology and a heightened sense of cultural Imagination. My sources repeatedly return to the question: How does our current relationship to A.I. reflect past human relationships to new technologies? By situating these encounters within the longer held tradition of symbolically-associated modes of technological experience, this paper aims to illuminate how our relationship to communication technologies continue to

shape our understanding of connecting with the Sacred in the context of our allegedly “secularized” Modernity. I focus heavily on the framework developed by Josephson-Storm to describe this latter term. Ultimately, there is a rich history of how we discuss and experience new technologies in America—recognizing this pattern helps to explain the emergence of spiritual A.I. chatbot interactions in this particular historical moment.

Abstract Name: Quantifying Multi-Modal Generative AI-Driven Cyber Risks in Cyber-Physical Systems Using Conditional-Value-at-Risk

Artificial Intelligence (AI) introduces cybersecurity risk in Cyber-Physical Systems (CPS) due to the capability of synthesizing sensory data. The goal of this research is to identify the risk of AI-generated attacks in CPS. This work creates a CPS testbed that consists of two occupancy sensors as well as an MQ2 Gas sensor that are installed on top of a raspberry Pi, which acts as a client while a computer plays the role of an asynchronous server to collect the real data. This work proposes a Multimodal Autoencoder (MMAE)-based generative AI model to generate poisoning attacks in CPS. The MMAE allows the system to have one autoencoder, with n encoders, one shared latent space, and n decoders (n , signifying the different types of data sets) to capture multi-modal sensory observation. The developed MMAE processes and trains on data from various sources which achieves a more accurate outcome than a model that only uses one type of data. This acts as the AI to simulate sensor values to then quantify Conditional-Value-at-Risk (CVaR) between the AI-generated and sensory captured values to measure the risk of cyberattacks in CPS. CVaR measures the average loss in the extreme tail beyond a specified confidence level, providing a clearer view of worst-case risk. The experimental results show that the occupancy sensor achieved 100% reconstruction accuracy within a 3 cm distance range. For the 95% and 99% confidence levels, the corresponding cybersecurity CVaR intervals were $(-1.80, 1.60)$ and $(-2.10, 1.90)$, respectively. The MQ-2 gas sensor similarly achieved 100% reconstruction accuracy within a 3-ppm concentration range, where 95% and 99% CVaR intervals were $(-0.040, 0.070)$ and $(-0.060, 0.080)$, respectively. As the use of AI increases, so does the potential for malicious activity within cyber-physical systems.

Abstract Name: Subcutaneous and Sublingual Immunotherapy for Allergic Rhinitis

Allergic rhinitis (AR) is a chronic immunological disease that significantly reduces quality of life and imposes substantial physical and economic burdens. Allergen immunotherapy (AIT), delivered as subcutaneous (SCIT) and sublingual (SLIT) treatment, is the only disease-modifying treatment that targets the underlying cause of AR. However, adherence to both forms of AIT remains low, with most patients failing to complete the minimum treatment duration of 3 years needed to achieve long-term benefits. This review evaluates the efficacy, safety, and convenience of SCIT and SLIT to determine which approach is most advantageous for managing AR. Studies show that both treatments effectively reduce symptom severity and

improve quality of life across adult and pediatric populations, with no major differences in overall efficacy. However, safety profiles differ: SCIT carries a higher risk of serious systemic reactions, while SLIT is primarily associated with mild, localized effects. In terms of cost, SLIT tends to be a more economical alternative, largely due to reduced clinic visits. Nevertheless, both treatments are more effective and financially advantageous over treatment with only medication. Despite clear clinical and economical benefits, persistence and compliance rates remain low for both immunotherapies, emphasizing the need for improved patient education and support. Ultimately, the choice between SCIT and SLIT should be guided by patient preference, convenience, and clinical direction within a shared decision-making model. Aligning treatment with patient values can improve long-term adherence and overall health outcomes, especially for management of chronic diseases.

Abstract Name: Cost Barriers to Adoption: A Call for Change

Over a hundred thousand children sit in the adoption and foster care systems waiting to be given a home, but the staggering cost of private adoption to families deters many. A study by the Dave Thomas Foundation found that over a third of adults in the United States have considered adoption, but only about 2-4% of adults actually adopt (Adoption Network, 2022). There are thousands of families with a desire to adopt and thousands of children wishing for a permanent home, yet the low rates of placement suggest that there are factors preventing families from adopting. While there are studies researching adoption and its effects, there is a paucity of research examining the relationship between cost and adoption rates. Thus, we decided to undertake a study inspecting the role that cost plays in the private adoption process. This project will be a qualitative phenomenological project, analyzing qualitative interviews of those who have seriously considered adoption or have adopted. Our research investigates the following: Does the high cost of private adoption deter families from adopting children? We hypothesize that there will be a significant relationship between financial barriers to adoption and adoption outcomes.

Abstract Name: The Relationship between Spiritual Well-Being and Mental Health of Commuter and On-Campus College Students

The purpose of our study is to examine the relationship between the spiritual well-being and mental health of students living on campus and that of commuter students. Mental health struggles are a prevalent issue among college students according to Emmerton et al. (2024). The college experience can be vastly different between commuters and residents; consequently, there may be a difference in these students' mental health. The empirical study of Kharameh et al. (2016) has revealed that religiosity has improved mental health in

students. However, there is very limited research exploring the relationship between the spiritual well-being and mental health of college students. Hence, we decided to undertake this study. Mental health setting is one of the major settings in which social workers are employed at and our profession requires social workers to undertake spiritual assessment of our client populations. Thus, this study will help us understand the mental health issues of our future client populations and whether spiritual well-being has any bearing on their mental health which might enable us to serve them better. Our research question is as follows: What is the relationship between the spiritual well-being and mental health of college students living on campus and commuters? We hypothesize that there is a statistically significant relationship between the spiritual well-being and mental health of college students. We also hypothesize that there is a statistically significant relationship between the mental health of commuting students and on campus students.

Abstract Name: Genomic Analysis of Cold-Adapted *Sulfitobacter pontiacus* from Antarctica

The Antarctic region is described as a frigid, oligotrophic environment. During a November 2009 expedition, phytoplankton were observed in the bottom 5 cm of the sea ice cores collected from Ross Sea, McMurdo Sound Station, Antarctica. This study focuses on understanding which type of heterotrophic bacteria are associated with these algae/phytoplankton and whether they have the genomic capacity to utilize these carbon sources. To test this, we used an enrichment culture approach using laminarin and cellobiose as the sole carbon source. The resulting microbial growth was serially diluted and plated on seawater-complete media (SWC), from which four well-isolated colonies (01DW25, 04NG25, 01KJ25, and 01JM25) were selected for pure culture. The 16S rRNA gene was amplified and sequenced. The phylogenomic analysis identified these isolates as *Sulfitobacter pontiacus*. Growth rate estimates on SWC and defined media showed that these isolates did not utilize beta-glucan, suggesting that other microbes had broken down algal polysaccharides into oligo- and monosaccharides (public goods) before isolation. Whole-genome shotgun sequencing and comparative genomic analysis with ANVIO confirmed that the Average Nucleotide Identity (ANI) between the *S. pontiacus* isolates and their closest relative, *S. pontiacus* (GCF_022788675.1), is 97.9%. CAZyme screening showed 22 glycoside hydrolase genes and 37 glycosyltransferase genes. These findings suggest that these psychrotrophic strains have the capacity to break down complex carbohydrates and adopted an energy-conserving strategy called carbon catabolite repression in the lab, which implies that these isolates represent a cheating strain of *S. pontiacus* that likely uses cross-feeding to sustain itself within Antarctic microbial communities, given the inherent costs of resource acquisition in a cold, oligotrophic environment. Future proteomic analyses will investigate specific proteins involved in carbon utilization and environmental responsiveness.

Abstract Name: Unseen and Unsupported: The Experiences of Non-Nuclear Family Students in Higher Education

Societal definitions of family are typically limited to a heteronormative, white, never-divorced, two-parent household. Despite the diversity of family structures among students, higher education continues to uphold the traditional nuclear family model. University structures and processes—from application language, mailings, and tuition payment to campus family weekend(s), academic breaks, and mental health resources—have been developed without fully considering students from non-nuclear families, creating a gap in support and inclusion. Between 25% and 35% of today's college students come from divorced families. Additionally, students come from grandparent-led families, queer families, foster families, and guardianless households. The persistence of an outdated societal ideal of the nuclear family continues to shape university policies and practices, reinforcing exclusionary assumptions. Yet, how these biases, along with the lack of intentional acceptance of diverse family structures, impact students' college experiences remains largely unexamined. To address this lack of exploration, the researchers gathered qualitative data from thirteen interviews with students from non-nuclear family structures. In addition to this, two interviews and two focus groups were conducted with university faculty and staff who engage with this population. This qualitative data was coded and analyzed, allowing for emerging themes to be presented and discussed at NCUR. Dominant themes reveal patterns of parent-student conflict, feelings of isolation from peers, financial strain, and other impacts on college student well-being. This research has already begun to inform practices at the researchers' home institution, sparking conversations and policy shifts in supporting this underserved and understudied population. Furthermore, it has the potential to impact best practices across higher education, encouraging institutions to more intentionally recognize and support the full diversity of students' family experiences.

Abstract Name: No Childhood at Arms: Why DDR Fails Former Child Soldiers in Ethiopia

Children recruited into armed groups face lifelong harm, yet Disarmament, Demobilization, and Reintegration (DDR) programs are typically designed for adults. This study investigates why Ethiopia's DDR efforts fail former child soldiers and what child-centered reforms are needed. The research combines policy analysis with qualitative data from thirty former child soldiers (twenty-three men and seven women) aged nineteen to sixty-eight, now living in Ethiopia (forty percent) and the United States as asylum seekers (sixty percent). Participants represent two cohorts: an older generation recruited at ages nine to twelve during earlier civil conflicts, and a younger generation recruited at ages fifteen to seventeen during the 2020–2022 Tigray war. Using semi-structured interviews and short surveys analyzed through thematic coding, the study evaluates reintegration across four areas: education, livelihoods, psychosocial recovery, and social acceptance. Findings reveal persistent gaps. Only forty percent of participants are enrolled in school or training, while seventy percent of the remainder wish to return but lack support. Just thirty-one percent report stable employment. About three-quarters experienced stigma in their communities, and two-thirds received no counseling. Women reported layered stigma and fewer opportunities to return to school or work. Participants attributed poor outcomes to short program timelines, limited child-specific services, and weak coordination among government and nongovernmental actors. Comparing Ethiopia with child focused DDR models in Sierra Leone and Uganda suggests practical remedies: guaranteed educational re-entry, trauma-informed counseling, mentored livelihood programs, and community reconciliation initiatives. Ethiopia's DDR model stops at demobilization and fails at reintegration for children. This project proposes a child centered DDR framework aligned with the Convention on the Rights of the Child and regional African norms, outlining policy steps for education, mental-health care, economic reintegration, and community acceptance.

Abstract Name: Effects of Intermittent Fasting and Diet on Longevity in Flies with Silenced Single-minded Neurons

With the rising prevalence of diabetes and obesity, the need to understand the genetic and physiological causes of these conditions is paramount. The single-minded gene has been shown to regulate appetite, energy balance, and lifespan in animals. We have found that silencing single-minded neurons in *Drosophila* increases the feeding rate of larvae and shortens lifespan. Two effective approaches for reducing weight and mediating the effects of diabetes are intermittent fasting and low carbohydrate diets. In this study, we subjected both flies with silenced single-minded neurons and wild type flies to intermittent fasting and low sugar diets and monitored their lifespans relative to continuously fed controls. Surprisingly, we found that females outlived males under all conditions and that a combination of a low sugar diet together with intermittent fasting was more harmful than continuous eating and intermittent fasting alone. These results suggest that the combination of intermittent fasting and low sugar diets does not increase lifespan in the flies, and suggest that single-minded activity affects lifespan and energy regulation during periods of starvation.

Abstract Name: Optimization of Marine Debris Collection Considering Environmental Factors

In Tokyo Bay, large amounts of marine debris are having a serious impact on the natural environment and ecosystems, and there is an urgent need to establish methods that can address this problem efficiently under limited resources. In this study, we propose a method for optimizing marine debris collection routes in Tokyo Bay based on a mathematical model that explicitly incorporates dynamic natural conditions. Conventional collection strategies have not sufficiently accounted for dynamic environmental factors such as tidal currents and wind direction, resulting in inefficient route planning. Although predictive technologies considering environmental factors have been partially introduced by agencies like the Ministry of the Environment, mathematical route optimization utilizing such data has not yet been implemented. To overcome this limitation, we construct a detailed mathematical model of the distribution and movement characteristics of marine debris, using multifaceted information including historical meteorological and oceanographic data as well as observed drifting patterns of debris. Based on this model, we design collection routes by applying an optimization approach based on the Traveling Salesman Problem. The objective of the optimization is to minimize the travel distance of collection vessels while maximizing the total amount of debris collected. To reflect operational realities, we impose constraints that prioritize “high-density regions,” ensuring that the selected collection points meet a predefined target volume. Furthermore, this model enables more precise route planning by incorporating the realistic factor that debris positions drift due to environmental factors such as wind and tidal currents, thereby causing dynamic changes in travel costs between locations. Numerical simulations conducted to validate the effectiveness of this model confirmed that routes reflecting drift predictions enable debris collection via the shortest path while achieving the target collection volume.

Abstract Name: The Coal Seams at the End of the World: Early Industrial Coal Mining on Svalbard

The Arctic Archipelago Svalbard occupies a unique place in global industrial history. In 1899, a Norwegian sealing captain, Søren Zachariassen, became the first person to commercially mine and sell coal on Svalbard. This inaugurated a rush of prospecting and industrial mining activity on the archipelago as industrialists from across Europe and the United States sought to locate and freely exploit coal seams across Svalbard. Those seeking to exploit this opportunity dealt with two primary concerns that, when combined, generated a unique set of operational challenges to mining on Svalbard. First, mine operators leveraged Svalbard's international status as *terra nullius* (no man's land) to conduct operations outside of industrial and labor regulations that drove up costs elsewhere in Europe and the United States. Second, mine operators had to contend with the natural challenges of working in an Arctic environment with ever-shifting sea ice and weather conditions, as well as the long, dark polar winter. This project explores how two mining companies, the American-owned Arctic Coal Company (ACC) and the British Spitsbergen Coal and Trading Company, developed mining operations in this unique environment on Svalbard in the early 20th century. The research supporting this endeavor represents a focused synthesis of robust scholarship and archeological analyses of the ACC's operations at Old Longyear City and the British Spitsbergen Coal and Trading Company operations at Advent City produced by the Large-Scale Industrial Exploitation of Polar Areas (LASHIPA) project. Using the insights from the LASHIPA project, this analysis focuses on understanding the material and social history of the mining operations of these two companies at Old Longyear City and Advent City and how Svalbard's international legal status and Arctic environment impacted the conduct, and ultimate demise, of these operations.

Abstract Name: Objective Measurement of Post-Stroke Activity Levels: A Longitudinal Evaluation Using the McRoberts Monitoring Belt

Stroke is a leading cause of long-term disability, often resulting in reduced mobility and difficulty completing daily activities. Traditional clinical assessments provide only brief snapshots of functional ability, making continuous monitoring useful for understanding a survivor's real-world activity patterns. This study used the McRoberts Stroke Monitoring Belt, a wearable device that tracks posture, step count, and energy expenditure, to evaluate daily functional engagement in a stroke survivor over a fifteen-day period. Adult stroke survivors were recruited from rehabilitation centers and instructed to wear the device continuously while maintaining their usual routines. The belt recorded posture classification, movement type, steps taken, total energy expenditure, and Physical Activity Level (PAL), allowing for an ecologically valid assessment of activity outside clinical settings. The participant, SRS01, wore the device for 99% of the monitoring period, providing comprehensive data. Results demonstrated a highly sedentary lifestyle, with 87.9% of the day spent inactive, including 38.7% lying and 49.2% sitting. Only 8.4% of the day was spent standing, and a combined 2.8% involved walking, shuffling, or stair climbing. Energy expenditure reflected similar patterns, as sitting accounted for 50.2% of total energy expenditure, followed by lying at 31.1%. Although stair walking required the most energy per minute, it occurred only 0.2% of the time. The participant averaged 1,797 steps per day and recorded a PAL of 1.28, both well below clinical recommendations for stroke recovery. These findings

highlight significant limitations in daily movement despite preserved capacity for brief, energetically demanding activity. Continuous monitoring provided detailed insight into real-world behavior, offering valuable information for clinicians to tailor rehabilitation strategies, identify barriers to mobility, and develop individualized recovery goals.

Abstract Name: TCF1 Represses the Expression of Pou2af1/OCA-B in JurKat cells

The advent of immune checkpoint inhibitors (ICIs) has revolutionized cancer therapy by reactivating T cells against tumors. However, this potent anti-tumor immunity often triggers immune-related adverse events (irAEs) due to excessive immune activation. A critical goal is to identify molecular regulators that can uncouple potent anti-tumor responses from pathological autoimmunity. The transcriptional coactivator OCA-B, encoded by Pou2af1, is essential for memory CD4+ T cell development, a population vital for durable tumor control. As these cells may also drive irAEs, OCA-B represents a therapeutic double-edged sword. Intriguingly, OCA-B expression is inverse to that of the transcription factor TCF1: TCF1 is high in naïve T cells and declines upon activation, while OCA-B is low in naïve cells and increases. This pattern suggested TCF1 might directly repress Pou2af1 to regulate OCA-B. We investigated this using a luciferase reporter assay. The Pou2af1 control region was cloned upstream of a luciferase gene. We designed three constructs: a wild-type sequence, a variant with a mutated canonical TCF1 binding site, and a variant with an additional mutation at a downstream putative site. These were transfected into JURKAT and SUPT1 T cell lines. In two out of three independent experiments, the presence of wild-type TCF1 binding sites significantly reduced luciferase activity compared to mutated sites. This supports a model where TCF1 acts as a transcriptional repressor of Pou2af1. Our findings establish a novel repressive relationship between TCF1 and OCA-B. This TCF1-OCA-B axis presents a promising therapeutic target. By understanding how to selectively modulate this pathway, we may engineer T cell responses that enhance ICI efficacy while constraining irAEs, aiming to separate anti-tumor immunity from its toxic side effects.

Abstract Name: Enhancing Agrochemicals to Combat Pesticide Resistance

The agricultural industry relies on the use of pesticides to produce high yielding crops to feed the nation. It is estimated that 10-23% of crops grown yearly are lost to fungal infections, and the slow pace of new or modified agrochemicals entering the market is contributing to rising levels of pesticide resistance. The element fluorine is broadly biologically active and remains active longer than other elements, making it an

element of interest in modern day agrochemical synthesis. The goal of this project is to determine the effectiveness of modified agrochemicals as well as any potential toxicity they may pose toward end consumers. The candidate antifungal drug Griseofulvin was used to establish a baseline concentration of toxicity to *Microsporum gypseum* followed by toxicity assays on RAW 264.7 and C2C12, macrophages and myoblast cell lines respectively. Activity of the antifungal on *M. gypseum* was determined by disk assays measuring zones of inhibition created by the fungi. Toxicity towards mammalian cells was then analyzed at the determined concentrations. Through collaboration with UW-Platteville's agriculture department, we hope to determine if modified griseofulvin is a candidate pesticide for corn and/or soybeans, common crops grown in Wisconsin. We anticipate that modifying agrochemicals will help combat issues of pesticide resistance for the agricultural industry.

Abstract Name: Does Childhood Financial Instability Influence Financial Solvency in Adulthood?

This research studies the relationship between childhood financial instability and how that correlates to their financial solvency as an adult in the United States. While there are several studies that discuss the effects of one's childhood financial instability on their academic outcomes, there are few that consider their effect on their financial solvency in adulthood. Data from the National Longitudinal Study of Youth (NLSY) will be used to study the correlation between childhood financial instability and adulthood financial solvency. Through which the research aims to understand the long-term effects of growing up in a financially instable household. The expected result of this research is to have a broader and deeper understanding of how these variables can affect the long-term chances of individuals' success in life. This topic has important policy implications that will encourage policy changes that can prioritize support for underprivileged children, along with highlighting the importance of education and financial literacy.

Abstract Name: Predicting the Overall Stability of Airplanes Using AI Machine Learning Techniques

AI and machine learning (AI/ML) techniques are now widely used to develop predictive models across medicine, engineering, and other scientific disciplines. Despite this broad adoption, their integration into aerospace engineering remains comparatively limited. One of the primary reasons is the scarcity of accessible, high-quality experimental data, as aerospace companies often withhold proprietary information due to commercial, security, and competitive constraints. Consequently, researchers face challenges in training and validating robust AI/ML models for aerospace applications, underscoring the need for open datasets. Currently our work involves a dataset on Kaggle, an open-source website. In this work we utilize IBM Watson and a 90:10 split for training and testing data, with two models created per variable. For weight

efficiency and vibration damping, IBM Watson created a Snap Decision Tree Classifier (~41% accuracy) and a Snap Random Forest Classifier (~40% accuracy); for durability, IBM Watson created a Snap Logistic Regression (~48% accuracy) and Snap Random Forest Classifier (~48% accuracy). E (GPa) and Optimization were the two most important factors in predicting each of the three target variables. The low accuracies of each model gave insight to the complexity of predicting each target variable, as each was affected by a combination of other factors. In order to investigate the impact of split ratio for the treating and testing data, current work is dedicated to using the same dataset with few more algorithms. New results are comparatively encouraging and are being compared to our previous results. Our presentation will include full details on various algorithms employed to develop these predictive models and will provide a detailed discussion on results.

Abstract Name: From Transfer to Triumph: Institutional Support and Faculty Relationships as Catalysts for Black STEM Students' Achievement at HBCUs

Black students who transfer to Historically Black Colleges and Universities (HBCUs) often seek cultural affirmation and institutional support after racially hostile or unwelcoming experiences elsewhere. Yet Black transfer students can face gaps in onboarding and faculty engagement that threaten persistence. This study examines how institutional support and student–faculty relationship quality influence academic motivation and achievement among Black transfer students at HBCUs. We hypothesize that students who perceive high institutional support and faculty warmth will report greater motivation, persistence, and improved course performance. Using data from a larger NSF-funded project, we analyze surveys from 267 Black undergraduate transfer students in introductory STEM courses across 32 HBCUs. Literature indicates that students transfer seeking psychological safety, cultural belonging, and stronger mentorship. We will use hierarchical linear modeling to test links among institutional support, student–faculty dynamics, motivation, and achievement. We expect stronger perceived institutional and faculty support to be associated with higher motivation and course achievement. Thematic analysis of open-ended responses should show that cultural affirmation and negative prior institutional experiences drive transfer decisions. This study addresses a critical gap by focusing on Black transfer students at HBCUs, an often-overlooked population in transition research. Ultimately, we aim to advance equity in higher education by clarifying the structural and relational conditions that foster success for Black students navigating transfer pathways.

Abstract Name: The Relationship Between Anxiety Symptoms and Hypertension Among Adults in the U.S.V.I

Hypertension is a major health concern in the United States Virgin Islands (U.S.V.I.), affecting a large portion

of adults. Moreover, community health assessments report rising stress levels and limited access to mental health services. Despite the increase in these conditions, little is known about how these conditions potentially overlap and interact in designated health professional shortage areas, such as the U.S.V.I. While participating in a research fellowship addressing cardiovascular health in the USVI, the prevalence of anxiety and hypertension among USVI adults was examined and the relationship between anxiety symptoms and self-reported hypertension was evaluated. From July 8th to July 12th, 2025, surveys were administered to 105 USVI adults at various community locations. The 15-item survey combined specific items from the Generalized Anxiety Disorder 7-item Scale (GAD-7) and the WHO STEPS survey instrument. Demographics were determined by five questions adapted from the Behavioral Risk Factor Surveillance System (BRFSS). Data was entered into the IBM SPSS software, where independent sample t-tests and a Pearson correlation test were performed. No relationship was found between anxiety and hypertension. Participants with diagnosed hypertension who were adherent to medication were much older than those without diagnosed hypertension. Given the small sample size and convenience sampling, coupled with the context as a research training activity, significant outcomes were not expected. Further limitations include a lack of variability due to a small sample size and the inherent biased nature of self-reporting; however, there were notable strengths as well, such as addressing the gap in research, utilizing well-established scales with good psychometric properties, and being conducted amongst an underrepresented population. As for future studies, researchers may want to conduct this study in a qualitative manner to gain better insight, pool participants from the other U.S.V.I. islands (St. Croix, St. John, and Water Island), or investigate other moderating factors.

Abstract Name: Using Aromaticity to Design Single-Molecule Electronics

Single-molecule electronics utilizes molecular components to reach miniaturization limits for electronic devices. They offer several advantages, including extremely small size, high efficiency, and low material costs. Furthermore, they provide a unique opportunity to explore how a molecule's chemical properties influence its electronic behavior. Understanding the specific effects of molecular design on electron transmission through individual molecules is central to progress in this field. Aromaticity refers to the stability found in cyclic, planar, conjugated π -electron systems. In contrast, antiaromatic molecules are destabilized due to the arrangement of π electrons within their cyclic structures. These variations significantly affect a molecule's electronic structure, energy level distributions, and electron transport behavior. We have used computational chemistry to investigate structure-property relationships in molecular design based on structural features and aromaticity in single-molecule junctions. We have extended this study to investigate the role of aromaticity in the function of single-molecule photoswitches. Our results can be used to guide the design of single-molecule electronic devices and may offer new insight into nanoscale devices and confined molecular systems.

Abstract Name: Evaluating the Effects of Environmentally Relevant PFAS Mixtures on Human Cell Viability and Mitochondrial Density

Per- and polyfluoroalkyl substances (PFAS) are synthetic, long-lasting compounds widely used since the 1940s in commercial and industrial products. Because of their strong carbon–fluorine bonds, PFAS persist in the environment and accumulate in living organisms, leading to contamination and health risks such as cancer, immune disruption, and hormonal imbalance. While most toxicological studies focus on individual PFAS, real-world exposure occurs as mixtures. This study aims to evaluate the toxicity of environmentally relevant PFAS mixtures on human cells, focusing on cell viability and mitochondrial density to better understand combined chemical effects. Human colorectal carcinoma (HCT 116) cells were exposed for 24 hours to seven treatment groups: two PFAS mixtures and five individual compounds (PFOA, PFOS, PFBA, PFBS, PFHxS) at environmentally relevant concentrations ranging from 0.1 nM to 1 μ M. Mixture 1 consisted of equal proportions of the five PFAS, while Mixture 2 reflected realistic blood-level ratios from Minnesota biomonitoring data. Cell death and mitochondrial density were quantified using fluorescence microscopy and analyzed with CellProfiler software to assess dose- and compound-specific toxicity. Preliminary analyses showed variability in cellular responses across all exposures. Mitochondrial density differed by compound and concentration; PFOS and PFBS produced the highest increases at 100 nM, while PFHxS caused reductions at higher doses. Both mixtures decreased mitochondrial density, with Mixture 2 exhibiting a stronger effect at 10 nM. While results were not significant, the variation in effects by compound mixture is indicative of the importance of studying biologically relevant exposure in addition to individual compounds and equimolar mixtures. Understanding these effects is critical for assessing potential risks to human health, particularly during sensitive periods of neurodevelopment.

Abstract Name: Mapping illness: Historical redlining injustices' impact on tuberculosis transmission

Tuberculosis (TB) remains a persistent public health challenge in the United States, with most jurisdictions suffering an outbreak in 2024. Historic discriminatory lending practices, including neighborhood letter grades assigned by the Home Owners' Loan Corporation (HOLC) in the 1930s, may contribute to TB transmission due to resulting poor housing conditions. This pilot study examined the association between the extent of “D” grades, what we call redlining today, and TB incidence rates in California, Florida, Massachusetts, and Washington. We downloaded historical HOLC data from diversitydatakids.com. We then converted the census-tract level data (2010 tracts) into the county-level average of the geographic area graded “D” for the four states. Using bivariate linear regression analysis in R, we explored the association between this average percent and CDC-reported TB incidence rates from 2010 and 2023. We found each additional percent of area graded “D” was associated with a 17% increase in 2010 TB incidence rate for the county, as well as an 11% increase in the 2023 TB incidence rate. Furthermore, the two models produced an adjusted R^2 of 0.134 and 0.161, respectively, suggesting that 13-16% of the variation in TB rates is explained by the single variable of average area graded “D.” Counties without any redlining data and no TB incidence were not considered in the models. We found a statistically significant relationship between the extent of redlining in a county and its 2010 and 2023 TB incidence rates in four states, despite the passage of over 70 years. This relationship remaining significant in the model using 2023 data may underscore how the COVID-19 pandemic emphasized many persisting health disparities. Our next steps are to account for additional control variables and incorporate redlining and TB incidence data for more states. The results suggest the need for structural changes to help achieve TB elimination goals.

Abstract Name: Associated Psychological Factors in Political Behaviors of First- & Second-Generation Immigrants

A common problem in psychology research is that it has largely favored the WEIRD population and uses broad cultural groups when analyzing data. This culturally insensitive view can affect how research is used in the application or understanding of behavior. A lack of a multicultural perspective was clear in the analysis of 2024 election research. This election was historic in many ways. It had the 2nd-highest voter turnout rate since 1908 and was one of the most polarizing in recent history. The increased voter turnout is understandable given that education levels and political participation rose at both the state and national levels throughout the 2020s. One of the biggest deciding issues in this election was immigration. Researchers often used broad (often racial) categories to analyze political decision-making and attitudes, particularly those of American immigrants. Inaccurate predictions and misinterpretations of behavior and attitudes are the result of using such overgeneralized categories, which ignore the subtleties of smaller group differences in behavior. This study aims to use a multicultural perspective to examine differences in political behavior across multiple immigrant groups living in Southern California. Using Berry's level of acculturation model, we investigate cultural differences in political behavior between first- and second-generation immigrants from various ethnic groups. Two dimensions from Hofstede's dimensions of culture, power distance and uncertainty avoidance, are used to gauge attitudes toward an immigrant's culture of origin.

Abstract Name: Establishment of a Conditionally Replicating Guinea Pig Cytomegalovirus Model for Molecular Characterization of Latency

Human cytomegalovirus (HCMV) is a member of the Herpesviridae that establishes life-long latent infections that pose risks of life-threatening disease upon reactivation in immunocompromised individuals. Understanding the molecular mechanisms that govern the latent state is critical for developing effective treatments. However, molecular characterization has been impeded by the scarcity of latently infected cells in vivo and the inability of current in vitro models to support the expansion of clonal latent cell lines. To address these limitations, we developed a novel cell culture model utilizing a conditionally replicating guinea pig cytomegalovirus, a relative of HCMV that mimics HCMV pathology and provides a valuable animal model. We engineered a recombinant guinea pig cytomegalovirus, GP56/52-DD, in which two essential viral replication proteins are fused to a destabilization domain. This genetic modification creates a molecular switch controlled by the synthetic ligand Shield-1. The presence of Shield-1 stabilizes these proteins, permitting normal viral growth, whereas in sister cultures lacking Shield-1, the fusion proteins degrade, preventing lytic replication. Thus, in the absence of Shield-1, GP56/52-DD-infected fibroblasts are forced into a latent state. Preliminary studies demonstrate that infections lacking Shield-1 result in long-term viral persistence without lytic replication. Addition of Shield-1 up to 84 days post-infection triggers reactivation to lytic replication, confirming the establishment of bona fide latency and suggesting that creation of clonal latent cell lines may be feasible. Three specific aims will be undertaken: (i) determine if latently infected cells can be propagated, (ii) establish if latently infected cells can be cloned to produce homogeneous cell lines, and (iii) identify viral proteins that are expressed during latency. Development of a similar latency system based on HCMV is in progress. Such conditionally replicating latency models may provide novel platforms for molecular characterization of latency, potentially revealing new targets for preventing HCMV disease.

Abstract Name: A3.M.P.: The future of cost-effective rehabilitative devices.

The goal of A3.M.P. (Affordable, Accessible, and Automotive Mechanical Prosthetic) was to improve the overall design and objectively improve the functionality of the previous prosthetic arm made, while taking into consideration what most amputees deem necessary in an upper rehabilitative device and remaining cost-effective. The construction of the elbow-disarticulation-focused upper rehabilitative device was dependent on optimal sensory detection (EMG Signal Recognition), proper movement of the prosthetic arm in its different poses during testing, and cost-effectiveness. This was done by collecting the most accurate readings from the three EMG muscle sensors. The graphs titled "EMG Signal Recognition" show, by pose (fist, rest, stretch, and

peacesign) the individual samples taken by the three sensors used. This time around, a significantly smaller set of values compared to previous research was used to facilitate device programming. The data would be compiled to form distinguishable ranges that could be identified as the poses. Furthermore, the table detailing the cost comparison of a generic prosthesis and the one in this investigation aims to check for the cost-effectiveness variable in this research. The prosthesis made in this investigation cost around \$287.44 to make, while a generic upper limb device can range in costs from 3,000 to 30,000 dollars. This shows that the production cost of the investigation is significantly lower than that of a generic prosthetic, complying with the cost-effective objective. Overall, the test hypothesis was corroborated, and the research was a success: all data points to optimal sensory detection and autonomous functionality in A3.M.P.

Abstract Name: The Visible and the Invisible Empires: Analyzing the Klan Through the Lens of Officiality

The Ku Klux Klan of the 1920s, regarded as the 2nd incarnation of this organization, was a dominant, nationalist group that held between 3-6 million members at its peak. The Klan was a political machine, retaining hundreds of politicians in its ranks, and sponsoring even more. It was also responsible for horrendous acts of violence against Black people, Jewish people, Catholics, and any other minority they deemed un-American. The Klan was made up of seemingly regular members of society turned hateful and led by demagogues who profited from the hate they propagated. There has been much literature on the Klan, mostly on different local branches and their actions, and sometimes on the national scope of the Klan, but this paper looks at both. Using stories recovered from archives that have never before been seen in the field, this paper details the rise of the Klan and the pushback against it in the 1920s, including brief adventures into Mexico and the reluctant acceptance of women into the Klan. This paper then seeks to analyze the organization through the lens of "officiality." That is, it seeks to separate the official actions of the Klan (those which were sanctioned by official leadership) and unofficial actions of the Klan (those which Klan officials pretended to denounce). This paper differentiates these facets so that individuals may recognize, both in historic and contemporary times, the patterns of nationalist movements, both on the ground level and the organizational level. Ultimately, this paper finds through anecdotes and analysis that the official Klan was essentially a gift, created and expanded to capitalize on hatred as a means of profit and power. And the unofficial Klan was the truly violent side of the organization that came as a result of the artificially-created hatred spread by the official Klan's words.

Abstract Name: Tension-Dependent Analysis of Marine Sponge Extract's Impact on Myofibroblasts affected by Dupuytren's Contracture Using OCT

Dupuytren's contracture is a condition where the tissue beneath the skin of the palm and fingers thickens and forms nodules, causing the fingers to bend inward. Over time, this can limit hand mobility and make it difficult to fully extend the affected fingers. It is propagated through over contraction of myofibroblasts. Prior experiments have been performed to provide preliminary data that supports the efficacy of inhibition of

myofibroblasts exposed to marine sponge extract (02PD1L). Preliminary data suggests that 02PD1L inhibits cell migration, furthermore through curvature measurements of 2D cross sections of collagen lattices have shown a significant decrease in tension generation by myofibroblasts treated with 02PD1L in comparison to non-treated cells. This project assesses the characteristics of 02PD1L. First, through 2D and 3D measurements of tension generation of myofibroblasts treated with extracts in high and low-tension environments utilizing optical coherence tomography. Secondly, through comparisons with current known microtubule inhibitors. Finally, coverslip analysis of microtubule characteristics through confocal laser microscopy. This data will define the effects of 02PD1L and will provide future valuable information to help explore the mechanisms and pathways of this experimental drug.

Abstract Name: β 1.2 Modulates Cellular Responses to Physiological Lactate Exposure in Kv1.5-Expressing HEK293T Cells

Lactate was traditionally viewed as only a metabolic waste product, but emerging cardiovascular research shows that cells can use it as both an energy source and a signaling molecule during cellular stress. During conditions such as ischemia, hypoxia, or accelerated glycolysis, lactate levels in tissues can rise to physiologic concentrations between 5-10 mM. These elevations can influence ion channel behavior, oxidative stress responses, and cell survival. Kv1.5, a voltage-gated potassium channel expressed in atrial cardiomyocytes and vascular smooth muscle cells, interacts with auxiliary beta-subunits such as β 1.2. However, it remains unclear whether β 1.2 changes how cells respond to metabolic stress signals like lactate. To address this, we conducted a study investigating whether β 1.2 alters cell survival rates under physiologic lactate exposure. HEK293T control cells expressing neither Kv1.5 channel nor β 1.2 subunit, HEK293T cells expressing Kv1.5 channel only, and HEK293T cells expressing both Kv1.5 and β 1.2 subunit were grown under the same growth conditions (37°C and 5% CO₂). All three groups underwent exposure to physiological concentration of lactate (8mM) for 30 minutes. For each trial (n=4), four “before” and four “after” images were collected for both the no-treatment control and lactate conditions. ImageJ software will be used to analyze these images and quantify changes in cell density. Preliminary imaging results showed a consistent pattern across all trials. In both control HEK293T cells and Kv1.5-only cells, 8mM lactate caused a decrease in cell density after 30 minutes. In contrast, Kv1.5+ β 1.2 cells did not show a decrease in cell density following lactate treatment. No changes occurred in the no-treatment conditions for all three groups. These preliminary findings suggest that β 1.2 may confer protection against lactate-induced metabolic stress. Future studies will advance our understanding of β 1.2’s role in pathological conditions where lactate accumulates.

Abstract Name: Exclusive and Polysubstance Use Associations with Mental Health and Social Support Among Undergraduate Students

Introduction: Though substance use is highly correlated with mental health and social support, there is more limited data regarding these relationships with polysubstance use. This secondary analysis aimed to explore associations between exclusive and polysubstance use, mental health symptoms, and social support. Methods: In Spring 2025, undergraduates at a large Central Virginia university (n=336) completed an online survey. Participants reported demographics, past 30-day alcohol, cannabis, and tobacco use, mental health symptoms (DASS-21), and perceived social support. Individuals were grouped by substance use behaviors (no substances, alcohol-only, alcohol+cannabis, alcohol+tobacco, all three substances). Due to limited sample size, cannabis-only, tobacco-only, and cannabis+tobacco groups (n=20) were excluded. ANOVA and t-tests compared mental health and social support between groups. Correlations between mental health symptoms and social support were assessed. Results: Participants were on average 20.2 years old, 81.8% female, 30.1% White, 24.7% Black/African American, and 14% Asian (remainder identified as other groups). Alcohol-only use was most prevalent (21.5%) followed by use of all three substances (14.0%), alcohol+tobacco (12.2%), and alcohol+cannabis (9.0%). The highest depression and stress symptoms were observed for those who used alcohol+cannabis and/or tobacco which were significantly higher than those using no substances or alcohol-only ($p < .05$). For anxiety symptoms, use of alcohol+tobacco or all three substances was associated with the highest levels which were significantly higher than those using no substances or alcohol-only ($p < .05$). Social support did not differ significantly between groups, but mental health symptoms were negatively correlated with social support ($r = -0.26$ to -0.29 ; $p < .001$). Conclusions: Findings highlight the prevalence of polysubstance use among undergraduates and associated mental health symptoms. Substance use prevention and intervention efforts should leverage protective social factors and provide mental health support.

Abstract Name: I Love You but I Don't Like You: Intergenerational Ambivalence and Grandparent-Grandchild Emotional Closeness

Older generations influence their grandchildren through child care and emotional connection. For grandparents, relationships with grandchildren provide a second chance at parenting and a sense of pride in continuing the family line. High intergenerational solidarity (family cohesion and sense of connection) strengthens relationship quality between children, parents, and grandparents. However, this only characterizes positive aspects of relationships, such as trust and affection, and excludes how family members may feel simultaneously positively and negatively towards the other (intergenerational ambivalence). High intergenerational ambivalence has negative effects on psychological well-being and is associated with increased stress levels. It is also possible that ambivalence in the relationship between parent and grandparent would affect the interaction quality between the adults and child. Therefore, in this study, I also examine sensitivity which encompasses the observed warmth, connection, and responsiveness between the adult and child. Specifically, I address the gap in the research on effects of intergenerational ambivalence, sensitivity, and emotional closeness. A total of 186 families engaged in 11 triadic (parent-child-grandparent) video chat sessions; for this study I will only be examining the baseline and final sessions. The parent and grandparent also completed self-report measures, including measures of intergenerational solidarity and emotional

closeness. Intergenerational ambivalence will be derived from these measures by computing the Griffin formula. Emotional closeness will also be measured in a self-report measure, and parent and grandparent sensitivity will be measured from observational coding of behaviors seen in video chat interactions. This study will examine whether higher levels of intergenerational ambivalence between parents and grandparents is negatively correlated with emotional closeness and observed sensitivity between grandparents and grandchildren. It is critical to analyze how parent-grandparent relationships subsequently affect grandparent-grandchild relationships and interactions for young children and this study is a first step in this important work.

Abstract Name: Bridging Healthcare Gaps: Evaluating Access, Service Utilization, and Barriers to Care at a Southern California Community Clinic

Access to quality healthcare remains a critical barrier for underserved communities, particularly racial and ethnic minorities and individuals without health insurance. These populations often face compounded challenges, such as language barriers, cultural stigma, limited transportation, and economic instability, which contribute to delayed care and poorer health outcomes. A Southern California free clinic aims to bridge this healthcare gap through a volunteer-driven model offering a variety of free services to low-income populations across Ventura County. To ensure high levels of care, the clinic performs an annual program evaluation. This study examined service utilization, patient outreach, and barriers to accessing healthcare. A total of 100 patient responses were collected across two locations. Responses were collected through a Google Forms survey with in-person interviews in order to accommodate for low literacy levels and limited internet access. Findings revealed that 64.3% of participants do not have access to healthcare outside of these clinics. 81% identified money as the biggest barrier to healthcare access, followed by fear (32.1%). 81% of participants reportedly learned about the clinic through friends or family. 93% of participants sought primary medical care and 70% used the food and clothing distribution. Meanwhile, 63% expressed a strong interest in accessing dental care. Additionally, 66% of participants expressed interest in TeleHealth options if unable to attend in person. These findings highlight the clinic's critical role in the community, supporting the need for continued free services. However, findings also point to key areas for future development, underlining outreach and expansion of services.

Abstract Name: Organelle Target Discovery in *Naegleria fowleri*: Drug Pockets, Serum Free Medium, and AI Triage in a Warming World

Naegleria fowleri is a thermophilic freshwater amoeba that causes primary amoebic meningoencephalitis, a

rapidly progressive brain infection with a case fatality rate exceeding 97%. As surface waters warm and recreational exposure increases, risk is expanding into regions that previously reported few cases. Current therapies rely on empiric multidrug regimens not designed for this organism and often initiated late in the disease course. This project integrates four components into a single pipeline that seeks mechanistic weak points in *N. fowleri* and links them to earlier clinical decision making. First, protein structure models and open structural biology tools such as PyMOL mapped candidate drug binding pockets on endoplasmic reticulum and mitochondrial proteins that diverge from human homologs. These analyses highlight secretory trafficking and mitochondrial metabolism as promising targets at the organelle level. Second, a simple serum free axenic culture medium (Montenegro's Medium) was developed and optimized to support robust *N. fowleri* growth at low cost while remaining stable during refrigerated storage, which facilitates routine culture in laboratories with limited resources. Third, this medium enabled a 96 well organelle targeted screen that combined endoplasmic reticulum stressors with metabolic modulators in amoeba only plates and in co culture with human cells. Across 24–72 hours, readouts included amoebic cell counts, a necrosis marker, and mitochondrial membrane potential. The NCUR presentation will illustrate drug combinations that drive *N. fowleri* into organelle stress while limiting early injury in the human cell layer, which suggests a tractable window for selective therapy. Finally, a prototype web application (Amoebanator) encodes published case series into a transparent 16 point primary amoebic meningoencephalitis risk score and produces printable summaries plus comma separated value logs suitable for future machine learning analyses. Together, these components outline an early pipeline that connects bench work and bedside decision support for a neglected but highly lethal infection.

Abstract Name: Evaluation of the Selectivity and Sensitivity of a Novel Molecularly Imprinted Polymer for Detection of Perfluorooctanoic Acid (PFOA)

Molecularly imprinted polymers (MIP) are synthetic molecules that are useful for detection of target analytes in a solution. They are synthesized by polymerizing functional monomers in the presence of a template molecule to form a specific binding site; the template molecule is then removed. We report herein the characterization and preliminary analytical performance of MIPs designed to absorb perfluorooctanoic acid (PFOA) in aqueous environments. Perfluoroalkyl substances are ubiquitous environmental contaminants resultant from both industrial and consumer products and have been implicated in a variety of human diseases. Initial evaluation of the success of molecular imprinting was performed by quartz crystal microbalance (QCM), in which a piezoelectric crystal is coated in the polymer and solutions are passed over the oscillating crystal. Mass deposition was quantified according to the Sauerbrey equation using the change in frequency of the resonating crystal. Using QCM, the binding capabilities of the MIP were assessed for the target perfluorooctanoic acid (PFOA) as well as acetic acid and octanoic acid to account for non-specific or functional group-driven binding. Finally, the performance of the MIPs as binding sites with other sensor architecture will be reported. When successful, the MIP may be incorporated as a critical component for PFAS detection in aqueous environments.

Abstract Name: Diet- Related Stress and Coping Behaviors Among Latin* Adults Living with Chronic Conditions in Rural Southwest Virginia During the COVID-19 PAndemic

Latin*adults living with chronic conditions are at heightened risk for poor COVID-19 outcomes and worsening disease management. Rural communities often face additional barriers, including limited healthcare access and economic constraints. Diet-related stress and coping behaviors are particularly important, as disruptions in food access and changes in eating patterns during the pandemic may directly affect chronic disease management. From May 2020 to February 2023, Latin* adults in rural southwest Virginia were invited to participate in an online survey administered via REDCap in English or Spanish. The survey included 80 questions, but this substudy focused on sociodemographic characteristics, chronic disease status, and diet-related sources of stress and coping behaviors during the COVID-19 pandemic. Data analysis was limited to descriptive statistics for sociodemographic characteristics overall and according to diet-related stressors and coping behaviors. One hundred and two Latin* adults were recruited, with the majority aged 30 or older (66.7%), female (67.6%), and earning less than 24,999 (54.9%). Less than a quarter(22.5%) reported living with a chronic condition (diabetes and/or hypertension). Among this subgroup, 30% identified access to food and 21% identified access to water as sources of stress during the pandemic. Slightly over a quarter (26.0%) coped by consuming comfort foods such as chips and candy, whereas 17.4% coped by eating healthier. These findings provide an snapshot of diet-related stress and coping behaviors among Latin* adults with chronic conditions in rural southwest Virginia during the COVID -19 pandemic. Reliance on comfort foods as a coping strategy may affect chronic disease management, highlighting the need for interventions that support access to healthy foods and culturally appropriate dietary coping strategies. Future research should examine how these behaviors influence long-term health outcomes and identify approaches to mitigate diet-related stress in rural Latin*communities.

Abstract Name: Division of Labor and Children's Outcomes During the Pandemic

The COVID-19 pandemic significantly disrupted the daily lives of families. Caregiver demands increased, and household dynamics were reshaped, creating a unique stressor that potentially influenced children's psychopathological development. This study examines the correlation between the division of household labor and children's psychological well-being, with a particular focus on internalizing and externalizing outcomes. In this study, parents (N = 363) of 4- to 10-year-olds living in the United States completed online questionnaires regarding demographics, children's strengths and difficulties, and caregiving hours. It was hypothesized that a greater imbalance in childcare responsibilities would be associated with higher levels of internalizing and externalizing behavioral outcomes in children. However, the labor difference was not significantly correlated with either externalizing ($r = -.044$, $p = .403$) or internalizing ($r = -.051$, $p = .330$) outcomes. In contrast, external and internal outcomes were strongly and positively correlated ($r = .685$, $p < .001$). The findings from this study suggest that the unequal distribution of childcare alone may not be a key predictor of children's psychological outcomes during times of crisis. Implications will be discussed.

Abstract Name: Emotional Engagement and Student Learning in Social VR

This research investigates how social virtual reality (VR) can enhance students' emotional engagement in college classrooms and its relationship to learning. As higher education integrates immersive digital technologies, questions about their usability and effects on engagement have grown (Marks & Thomas, 2022). Social VR—interactive environments where participants communicate through avatars—offers new opportunities to support engagement through a heightened sense of co-presence (Ahn et al., 2024). This study focuses specifically on emotional engagement, an often-overlooked aspect compared to cognitive and behavioral engagement. When students feel emotionally connected to their peers and learning environment, they are more likely to take creative risks, share original ideas, and collaborate meaningfully. The COVID-19 pandemic increased social anxiety and reduced students' sense of belonging (Ifenthaler et al., 2023), emphasizing the need for emotionally supportive learning spaces. Prior research suggests Social VR can provide alternative social channels that foster emotional engagement by offering immersive, expressive experiences not available in traditional classrooms (Scavarelli et al., 2021). The central research question examines how Social VR experiences influence emotional engagement and learning. A 2 (avatar personalization: low vs. high) $\times$ 2 (types of social interaction: guided collaborative vs. open informal) repeated-measures experiment will be conducted in FrameVR, a browser-based social VR platform. It is expected that personalized avatars and collaborative tasks will increase enjoyment, confidence in expression, and perceived connection. After each session, students will complete surveys assessing emotional engagement and learning, complemented by the researcher's observations and brief written reflections. Pending IRB approval, the study will be implemented in a Spring 2026 Mass Communication course. Results aim to deepen understanding of Social VR's role in fostering emotional connections within classrooms.

Abstract Name: Understanding Vaccine Hesitancy in Veterinary Medicine: A Review of Client Attitudes

Uncertainty toward vaccination, long recognized as a public health concern in human medicine, is increasingly emerging within veterinary contexts, posing risks to both animal and community health. This literature review and survey-based study examine the development, causes, and implications of reduced vaccine confidence in veterinary medicine, with emphasis on small animal and some large animal practices. The review combines historical and current research to explore how vaccination perceptions have evolved among veterinarians and clients, and how factors such as the COVID-19 pandemic have shaped current attitudes. The literature highlights recurring themes surrounding vaccine reluctance in veterinary settings. Client perceptions of safety, efficacy, and necessity are often influenced by misinformation, social media, and mistrust of professional recommendations. The overlap between human and veterinary vaccine discourse has contributed to skepticism toward both core and non-core vaccines in companion animals. Veterinarians increasingly report that these discussions require enhanced communication skills and empathy to address diverse client concerns. Differences in vaccination rates across regions and species further suggest that socioeconomic and cultural factors significantly influence vaccination behavior. The ongoing survey component assesses vaccine awareness, confidence, and communication practices among veterinarians and animal owners in Cache Valley, Utah. It examines factors such as perceived risk, information sources, and trust in veterinary expertise, as well as the influence of human vaccine attitudes on animal health decisions.

Although data collection is ongoing, anticipated findings aim to inform outreach strategies that strengthen education and rebuild client trust. Overall, this research emphasizes the importance of evidence-based messaging, transparency, and proactive communication in promoting vaccination as a foundation of preventive care, animal welfare, and One Health initiatives. Keywords: vaccine hesitancy, veterinary medicine, communication, public trust, vaccination uptake, One Health

Abstract Name: Characterization of the Early Spread of Alpha-synuclein in a Mouse Model of Parkinson's Disease

The neural dysfunction observed in neurodegenerative diseases has been linked to the misfolding of naturally occurring proteins. One of these proteins, Alpha-synuclein, is a hallmark of Parkinson's disease and Dementia with Lewy Bodies. Due to the ever-increasing rate of Parkinson's diagnoses, the pathology of Alpha-synuclein has been well studied to better understand the various stages of the disease. However, there is one critical gap in our understanding of the pathology: spreading in very early stages, which is crucial for timely diagnoses and treatment. To bridge this knowledge gap, I use a newly developed specialized mouse model that expresses Alpha-synuclein, linked to a green fluorescent protein. I inject this mouse line with a synthetic version of the naturally occurring Alpha-synuclein fibril aggregate, commonly used to explore the pathology of misfolding alpha synuclein, PFFs. The fluorescent marker in these mice, combined with the PFFs, allows me to track how aggregates spread between neurons and what percentage of the neuron they occupy. I will also use two-photon microscopy and a red-shifted calcium indicator to monitor calcium signaling activity. With this approach, I will monitor neuronal aggregation on either side of the cortex while simultaneously monitoring the calcium signaling activity of the same neurons daily for several weeks. Our results will show the day-to-day progression of Alpha-synuclein aggregation and the effects of aggregation on neuronal functioning, in comparison to that of neurons without fibrils. Developing a better understanding of the order and consequences of the early spreading of this protein could allow for a greater understanding of how to develop better early-stage treatment plans for diseases such as Parkinson's.

Abstract Name: Peer Support Specialists in Virginia's Therapeutic and Behavioral Health Courts

This qualitative analysis will explore the role and benefits that peer support specialists serve for both court personnel and participants within behavioral health and therapeutic court dockets. Peer support specialists are certified professionals with a lived experience of criminal justice involvement, serious mental illness, and/or substance use disorders. These individuals serve a unique role within the criminal justice system as liaisons between legal actors and defendants. Peer support specialists facilitate communication by helping court personnel understand defendants' experiences and by translating complex legal requirements and treatment stipulations for those they assist. Many individuals struggling with serious mental illness and/or substance use

disorder report feeling a stronger sense of kinship with peer support specialists and generally feel more comfortable revealing to them if they have relapses in their treatment. In the context of Virginia's therapeutic and behavioral health courts, my research examines the various roles that peer support specialists play in advocating for defendants, interpreting and communicating defendants' conditions to legal actors, facilitating assistance to those with structural challenges, and maintaining confidential, trust-based relationships within diversionary dockets. Additionally, I will explore recent tensions between organizations producing best practice guidance and peer support specialists, including debates surrounding their efficacy and calls in some jurisdictions to restrict them within alternative courts. The data for this research will be drawn from participant observations conducted across therapeutic and behavioral health courts, as well as semi-structured interviews with various team members, including docket coordinators, attorneys, probation officers, and peer support specialists themselves. Peer support specialists are a relatively contemporary addition to diversionary courts therefore inquiry into their position and any potential resistance is imperative in navigating the future of therapeutic and behavioral health courts and criminal justice diversion overall.

Abstract Name: Dead end? Alternative Life Strategies for Nematodes Who Lose Their Symbiont

Symbiotic relationships can range from flexible to extremely specific, with some organisms becoming so dependent on their partners that they can't survive or reproduce without them. In the obligate mutualism between insect-pathogenic nematodes (*Steinernema* spp.) and their bacterial partners (*Xenorhabdus* spp.), the nematodes typically associate with one bacterial strain. However, the bacteria can and will often associate with multiple nematode hosts. This asymmetry raises an important question: what happens when a nematode loses its bacterial partner? There are no barriers for coinfection and once inside the insect, the symbiont bacteria and the associated nematodes separate creating an opportunity, where the nematode may lose access to its native symbiont. In previous work, *Steinernema* affine nematodes grew and developed on non-native bacterial symbionts equally well as when on their own but were more likely to leave the host environment without a bacterial symbiont over carrying out a non-native symbiont. In this study, we are seeing if there are alternative strategies for nematodes that lose their bacterial partner and how these strategies affect reproductive success and virulence. We tested three hypotheses: first, the nematodes who have no bacteria will be faced with a "dead end" and won't be able to reinfect an insect essentially ending their line, secondly the nematodes that carry no bacteria can be "rescued" if exposed to their bacterial symbiont and reproduce successfully. Lastly, bacteria-free nematodes will be able to co-op a non-natively infected insect host, but at lower levels of success compared to those carrying a native symbiont. The nematodes with no bacteria and that had no opportunity to find a new bacterial partner didn't infect a new host therefore unable to reproduce. The nematodes without bacteria who were placed with their native and non-native bacterium were able to reinfect a host which potentially means they were "rescued".

Abstract Name: The Impact of Ornithine Decarboxylase 1 in Animal Models of Tauopathy

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by memory impairment, synaptic dysfunction, and neuronal loss, with abnormal aggregation of the tau protein serving as a major pathological hallmark. Polyamines are small aliphatic cations essential for cellular processes including growth, differentiation, and stress responses. Prior in vitro studies suggest that higher-order polyamines, such as spermidine and spermine, may reduce tau aggregation, indicating a potential therapeutic mechanism. However, we do not know how polyamines effects different forms of tau like P301L in vivo. In this study, we investigated how increased polyamine synthesis affects tau biology by targeting ornithine decarboxylase 1 (ODC1), the rate-limiting enzyme in polyamine production. Polyamine levels were enhanced through adeno-associated viral (AAV)-mediated overexpression of ODC1, with AAV-green fluorescent protein (GFP) serving as a control. rTg4510 transgenic mice expressing P301L mutant tau were used as a model of tauopathy. Tau expression and phosphorylation were evaluated using western blotting and immunohistochemistry with antibodies recognizing total and phosphorylated tau, including HT7, AT8, PHF1, and pSer199/202. Quantitative analyses were performed across multiple brain regions, including the hippocampus, entorhinal cortex, striatum, dentate gyrus, and CA fields. Western blotting revealed that ODC1 overexpression significantly increased levels of high-molecular weight phospho-tau and total tau compared to GFP controls. Consistent with these findings, immunohistochemical analyses demonstrated elevated tau accumulation across all regions examined. These results indicate that induction of polyamine synthesis through ODC1 overexpression exacerbate tau pathology in vivo, promoting the accumulation of oligomeric tau species. Collectively, these findings suggest that polyamines may differentially influence tau depending on tau conformation and disease context. Ongoing studies aim to define the balance between beneficial and detrimental polyamine signaling, with the goal of identifying novel therapeutic strategies to modulate tau pathology in AD.

Abstract Name: RNA Sequencing of Leishmania donovani: Differential Gene Expression to Identify Protein Targets

Leishmania donovani is a species of intracellular human blood parasite that causes visceral leishmaniasis, which is the most severe form of leishmaniasis. Current treatments for visceral leishmaniasis have significant side effects and emerging resistance. As a result, *L. donovani* is a target for several experimental treatments that aim to elicit programmed cell death, more specifically apoptosis, in the protozoan without damaging the host cell. Studies have shown that hydrogen peroxide (H₂O₂) causes apoptosis in *Leishmania* promastigotes. However, proteins, potential targets for treatment, involved in the pathway are currently unknown. In this project, we aim to use RNA sequencing to identify genetic differences in untreated and H₂O₂-treated *L. donovani* promastigotes. Cells were treated for 24 hours with various concentrations of H₂O₂ to determine the IC₅₀ concentration, the concentration required to inhibit cell growth by 50%. Next, cells were treated with the IC₅₀ concentration of H₂O₂. The mRNA was isolated from the treated and untreated populations at time 0 and 24 hours post treatment, mRNA was converted to cDNA, and cDNA will be sequenced. RNA sequencing will be used to analyze the transcriptome and identify differentially expressed genes. It is expected that the gene expression of *L. donovani* promastigotes treated with H₂O₂ should differ from those not treated.

Determining differential gene expression could help identify the proteins involved in the apoptosis pathway in *L. donovani* promastigotes treated with H₂O₂.

Abstract Name: Policy Diffusion and NIL Reform: Why a Federal Framework Could Level the Playing Field

Name, Image, and Likeness (NIL) rights have changed college athletics by allowing student-athletes to earn money from their personal brands. While this has created new opportunities, it has also led to confusion because there is no federal policy guiding schools. Instead, states have passed their own NIL laws, creating uneven standards and competitive differences. This policy brief acknowledges how NIL policies spread across states and what this means for fairness and compliance in college sports. The focus is on Texas House Bill 126, which lets universities pay athletes directly and requires contract transparency, and compares it to laws in California and New Mexico. The paper uses Policy Diffusion Theory to explain states acting quickly after the NCAA allowed NIL compensation. Three policy options are considered: continuing state-based approaches, creating a federal NIL framework, and increasing regulation of NIL agents and collectives. After weighing benefits and drawbacks, the brief argues that a federal NIL framework would provide the most consistent and fair system for athletes and universities. This approach would set clear rules nationwide, reduce compliance problems, and include protections for student-athletes. The research paper also mentions basic criteria for evaluating this solution, such as fairness and simplicity. By exploring these options, the research explains why federal action may be needed to address the challenges of NIL and maintain competitive balance in college

Abstract Name: Adaptation of an Invasive Tree Frog (*Osteopilus septentrionalis*) in Response to Hurricane Milton

In evolutionary biology, natural disasters, like hurricanes, have traditionally been thought of as genetic drift-inducing events that will remove individuals from a population at random. However, recent data have called this assumption into question, indicating that natural disasters can act as selective pressure events that can induce morphological changes in a population. However, research to date in this area has been limited to select taxonomic groups. For our project, we studied the invasive Cuban tree frog (*Osteopilus septentrionalis*), and its response to Hurricane Milton (October 2024). Specifically, we aim to determine if there are significant variations in key morphological characteristics in the same population pre- and post-Hurricane Milton. We collected frogs by hand from the New College of Florida campus in Sarasota, Florida (27.384586, -82.556209), approximately 6.9 miles from where Hurricane Milton made landfall. We collected 28 frogs before Hurricane Milton (08/09/2024) and 60 frogs after Hurricane Milton (10/25/2024). We used calipers to measure limb length and snout-vent-length (SVL) and used ImageJ to measure the toepad area and digit length. Once measurements have been completed, we will run analyses of covariance (ANCOVAs) for each morphological measurement to determine if there are any morphological differences between the pre-

and post-hurricane specimens. This data analysis will help to better understand the impact of hurricanes on the invasive species *Osteopilus septentrionalis*, and potentially provide insight into the role natural disasters play in facilitating natural selection, an important topic in the context of global climate change.

Abstract Name: Novel Combination Therapy with Sildenafil and Rapamycin Potentiates Doxorubicin-induced in Breast Cancer Cell Death.

Background: Doxorubicin (DOX) is a cornerstone of chemotherapy regimens for breast cancer, but it leads to development of drug resistance and multi-organ dysfunction including cardiotoxicity. Our previous studies revealed that Sildenafil (Sild, Phosphodiesterase 5 inhibitor) potentiated antitumor efficacy of DOX, while ameliorating DOX-induced cardiotoxicity and Rapamycin (Rapa, mammalian target of rapamycin, mTOR, inhibitor) also protected heart against myocardial injuries. In the present study, we examined whether a novel combination therapy with Sild and Rapa can potentiate DOX-induced breast cancer cell death. Methods & Results: Murine breast cancer cells, 4T1, were treated with DOX (1mM), and/or Sild (10mM) and Rapa (100nM) for 24-hr or 48-hr. Cell viability was measured using CellTiter 96 Aqueous One Assay and a microplate reader by setting absorbance to 490 nm. After 24hrs of treatment, cells were trypsinized and stained with Trypan Blue (TB). Both alive and dead (TB positive) cells were counted under a microscope to calculate the percentage of dead cells. After 24hrs of treatment, proteins were isolated from frozen 4T1 cells using Lysis buffer. Then, Western blot analysis was performed to examine the mTOR signaling (using p-mTOR, total mTOR, p-AKT, total AKT, p-S6, total S6 primary antibodies) and apoptosis (cleaved PARP antibody). Combination of Sild and Rapa significantly suppressed cell viability with enhanced cell death as compared to DOX treatment alone in 4T1 cells. Western blot analysis showed Sild+Rapa in presence of DOX suppressed phosphorylation as well as total expression of mTOR, S6 (marker of mTOR complex 1) and AKT (marker of mTOR complex 2), but induced cleaved-PARP level in 4T1 cells. Conclusion: Cotreatment with Sild and Rapa may represent a novel strategy to enhance chemosensitivity of DOX in breast cancer cells, which would have a significant impact on breast cancer patients subjected to chemotherapy. Abstract Name: Goal-Directed Predictors of Self-Esteem and Psychological Well-being

Self-esteem is widely recognized as an important part of psychological well-being, yet researchers continue to debate whether it actively shapes well-being or primarily reflects it. Prior work suggests that emotion regulation and self-control, which are both assessed in this study through self-report measures, may help explain how self-esteem relates to happiness and life satisfaction. The present project uses data from the Daily Sleep and Exercise Study, which follows 216 undergraduate students from George Mason University over the course of 29 days to examine their psychological experiences in everyday life and their daily health behaviors. Participants wore a smartwatch or fitness ring for eight consecutive days to track sleep and physical activity and completed brief morning and evening surveys during that period. They also completed three longer online surveys on Days 1, 15, and 29 that included measures of self-esteem, life satisfaction, happiness, perceived difficulties in emotion regulation, and trait self-control. This project examines whether self-esteem is linked to life satisfaction and happiness both directly and through its relationship with these self-reported regulatory traits, and whether these patterns remain consistent across the study period. Although the study does not assess objective life outcomes, previous research shows that self-esteem, emotion regulation, and self-control can influence academic, social, and health-related functioning, making it important to understand how they operate within subjective well-being. Both the Brief Self-Control Scale and the Difficulties in Emotion Regulation Scale have demonstrated strong reliability in clinical and research settings, which supports their use in examining psychological processes that are relevant to intervention and mental health treatment. The findings from this study aim to clarify how self-esteem and self-regulatory traits work together to support resilience, emotional balance, and positive self-perceptions among emerging adults.

Abstract Name: Neighborhood Cohesion and Psychosocial Well-Being: Differences by Race/Ethnicity

Perceived neighborhood cohesion, or the perception that one belongs with and can trust and rely on their neighbors, has been associated with greater psychosocial well-being, yet some research suggests the existence of racial/ethnic disparities in access to neighborhood cohesion. Furthermore, much of the existing research has investigated perceived neighborhood cohesion in relation to single aspects of psychosocial well-being, thus limiting the ability to assess it as a multidimensional construct. As such, the present study utilized an outcome-wide approach to investigate potential racial/ethnic differences in the associations between perceived neighborhood cohesion and four aspects of psychosocial well-being (i.e., life satisfaction, anxiety, perceived stress, and loneliness). Using data from the Health and Retirement Study, a U.S. nationally representative dataset of men and women aged 51 years or older, we tested the hypotheses that (1) higher perceived neighborhood cohesion would relate to higher life satisfaction and lower anxiety, perceived stress, and loneliness, and (2) that these associations would be stronger among non-Hispanic White participants ($n = 5,095$) compared to non-Hispanic Black ($n = 1,431$) and Hispanic participants ($n = 1,070$). Results from the present study supported both hypotheses: higher perceived neighborhood cohesion was significantly associated with higher well-being on all four psychosocial aspects adjusting for race/ethnicity, age, gender, and education level as well as the proportion of residents in the same neighborhood with a college degree or higher. Furthermore, perceived neighborhood cohesion was more associated with psychosocial well-being among non-Hispanic White participants compared to the racial/ethnic minority groups. These findings suggest both the potential benefits of perceived neighborhood cohesion in regard to psychosocial well-being, and that interventions to increase access to neighborhood resources should prioritize inclusivity to bridge cohesion across diverse U.S. populations.

Abstract Name: Leveraging Character Strengths in Multiple Sclerosis Employment Journeys

Employment is a vital contributor to psychological well-being, independence, and quality of life among individuals with multiple sclerosis (MS). MS is a neurological disorder and its symptoms can make it difficult to sustain employment and perform work tasks effectively. While most existing studies have focused on clinical or environmental barriers to employment, few have explored how positive psychological resources, specifically character strengths, may help individuals with MS maintain or regain employment. This study aimed to (1) examine differences in character strength profiles between employed and unemployed individuals with MS, and (2) determine whether higher character strength levels were associated with greater likelihood of employment. A total of 257 adults with MS (average age = 45.39 years; 82.1% female) were recruited through the National Multiple Sclerosis Society. Welch's t-test and hierarchical logistic regression were conducted. Results showed that employed participants scored significantly higher in judgment, perspective, perseverance, zest, social intelligence, teamwork, leadership, self-regulation, and hope compared to the unemployed ones. Total character strength scores were also higher among employed individuals, and greater overall strengths predicted higher odds of employment, explaining 7% of variance. These findings show that character strengths could help protect and support people with MS in their employment journeys. Integrating strengths-based assessments and interventions into rehabilitation and vocational counseling may enhance self-efficacy, motivation, and long-term work success.

Abstract Name: Examining the Effectiveness of Transcranial Direct Current Stimulation (tDCS) in Reducing Drug Craving Among Individuals with Methamphetamine Use Disorder (MUD)

Methamphetamine use disorder is a chronic condition that is associated with substantial cognitive and behavioral impairments and high relapse rates. Given the limited effectiveness of current treatments, there is growing interest in approaches that target neural circuits involved in craving and self-regulation. Transcranial direct current stimulation (tDCS) is a noninvasive neuromodulation technique that delivers low-intensity electrical currents to modulate activity in brain regions implicated in decision-making. TDCS is thought to enhance prefrontal control over reward circuits, potentially reducing craving. Across studies, stimulation intensity commonly ranged from 1–2 mA and targeted the dorsolateral prefrontal cortex for 20–30 minutes per session. This literature review evaluates evidence on the effectiveness of tDCS for reducing drug craving among individuals with methamphetamine use disorder. A search was conducted using one electronic database (PubMed) for studies published between 2020 and 2025. Five studies met inclusion criteria. Several studies reported reductions in craving following both single-session and multi-session tDCS protocols.

However, other studies observed comparable decreases in both active and sham conditions, limiting conclusions about the causal effect of stimulation. Differences in study design, stimulation parameters, and sample characteristics contributed to these mixed findings. Inconsistencies may reflect variability in craving measures, abstinence periods, and follow-up durations. Current evidence suggests that tDCS may have potential for craving reduction, but the research remains limited and inconsistent. Additional studies with larger samples, repeated-session designs, and standardized protocols are needed to clarify its clinical utility and inform future treatment development.

Abstract Name: The Prelimbic (PrL) to Dorsomedial Striatum (DMS) Circuit Differentially Encodes Punishment versus Effort in a High-Cost Cocaine Self-Administration Choice Test:

Substance use disorder (SUD) is marked by continued drug use despite escalating costs, such as increased effort or the risk of punishment. The prefrontal cortex (PrL) and dorsomedial striatum (DMS) are key regions involved in goal-directed decision-making, but it remains unclear whether this circuit differentially evaluates types of cost—such as physical effort and aversive outcomes like punishment. To test this, animals were trained to self-administer cocaine, followed by bouts of punished and effortful self-administration. We used this task to test the hypothesis that the PrL-DMS circuit may differentially encode punishment and effort, reflecting separate neural processes for evaluating aversive versus physically demanding options. We found that PL-DMS activity was significantly elevated in the 5 s period following cue delivery in the high conflict period only, confirming our hypothesis that this pathway is involved in high conflict self-administration. These findings will help clarify how this circuit contributes to cost-based decision-making and may offer insight into mechanisms underlying the persistence of drug use in the face of negative consequences. To address this, we developed a choice procedure in which rats selected between two cost-based options to obtain a reward: (1) a static, punished nose poke cue that delivered a mild fixed histamine catheter infusion upon reward delivery, and (2) an effortful nose poke cue that required a variable number of responses, allowing us to determine the effort level at which the animal values each type of cost (punished or effortful). This design enabled us to examine how animals weigh qualitatively different costs and adapt their behavior accordingly.

Abstract Name: Shoulder Mobility Imbalances between Division III Gymnasts and Track Throwers

In order to reach their full potential, college athletes train to be precise with each particular movement requiring high overall mobility, including their shoulders. In many sports, shoulders face immense strain but not all schools share the same resources to prevent mobility loss due to funding such as Division III. In this study, we set out to investigate the mobility differences between a typical overhead sport that is unilateral,

track and field throwers, and a bilateral sport, gymnastics. Both of these sports have athletes who focus on a dominant arm, however gymnasts also have movements that require equal usage of their shoulders compared to a typical thrower who focuses on their dominant arm. Due to the bilateral shoulder use, gymnasts do not fit the typical dominant side focused overhead sports, creating a gap in current knowledge that supplies ground for future testing. Using a goniometer, we assessed a sample of Division III gymnasts and track throwers between the ages of 18 to 22 for their internal rotation, external rotation, and total rotation of both shoulders. Initial findings show that gymnasts have a significant difference between their dominant internal and non-dominant internal rotation as well as between their shoulders on total rotation. There were also findings that gymnasts and track throwers have a significant difference between their dominant shoulder internal rotation and their dominant total rotation. These results align with research showing the dominant arm usage does impact internal rotation. However, typically the unilateral usage of the dominant shoulder use would show an imbalance, but these initial results show that there is a concern within bilateral sports such as gymnasts. This research helped to show that bilateral sports also require further research into shoulder mobility due to their unique set of movements and within the Division III college athletes population.

Abstract Name: Investigating the Role of Different Microbial Environments on Growth and Development of *Brachypodium distachyon*

Soil microbes play an important role in plant growth, nutrient uptake, and stress tolerance. Interestingly, studies have shown that a more diverse community of microbes can more effectively support plant growth. In this project, we tested how microbial communities from three different soil types in Contra Costa County (arid, suburban, and San Joaquin Delta) affected the growth of *Brachypodium distachyon*, a small grass plant used to study biofuels, compared to a nutrient growth medium control. Seedlings were grown hydroponically for four weeks in fabricated ecosystems called EcoFABs filled with soil filtrates made from each type of soil. We measured root and shoot growth weekly and analyzed the data using an image analysis software program called ImageJ. We predicted that bacteria from arid soil would promote the most growth because they are adapted to harsher environmental conditions. However, our results did not support this hypothesis. Instead, the delta soil filtrate produced the strongest root growth, with roots growing three times longer than those in the other treatments. Shoot growth was similar among all groups, with only small differences. Preliminary data suggests that the microbial communities are different across each soil sample and future studies will be aimed at quantifying this difference. Our results suggest that microbes from nutrient rich, water adapted delta soils may better support root development than those from arid or suburban soils. Overall, this study shows that soil origin plays a major role in how microbial communities influence plant growth and highlights the potential of soil microbes to support sustainable agriculture and reduce reliance on chemical fertilizers

Abstract Name: The Effect of Neuropeptide Y on Staphylococcus aureus Biofilm Production

Biofilm is a substance produced by many bacteria that protects those cells and provides them with nutrients. Bacteria that secrete biofilms can contribute to a form of bacterial antibiotic resistance, which is a growing public health concern and challenge to the field of medicine. As antibiotic resistance increases, it is critical to find alternative treatment options for bacterial infections. Staphylococcus aureus is an opportunistic pathogen and a main cause of community-acquired, nosocomial biofilm infections. S. aureus that enters the body via wounds or medical devices can cause severe infections. After entering the body, S. aureus cells progress through a series of stages that lead to the production of biofilm, making them less sensitive to the host immune system and more resistant to antibiotics. Antimicrobial peptides (AMPs) are an emerging factor of interest because of their size, accessibility, and capacity to prevent microbial growth. This research studies the effect of a specific AMP called neuropeptide Y on S. aureus biofilm production and bacterial survival. Following growth of S. aureus and treatment with neuropeptide Y, crystal violet staining and viability assays were used to measure biofilm production and bacterial survival. Our results so far indicate that neuropeptide Y has an effect at reducing biofilm at low production levels; however, it has no effect at decreasing survival rates of S. aureus.

Abstract Name: Effects of Steeping Temperature and Time on the Antioxidant Capacity of Cold Brew Coffee

Coffee is a major dietary source of antioxidants in North America and accounts for a substantial portion of daily antioxidant intake. While previous studies have shown that roasting conditions affect antioxidant availability, most investigations have focused on hot brewing methods. In contrast, limited research has examined how cold brew preparation influences antioxidant capacity, despite the beverage's increasing popularity. Because antioxidants are linked to reduced oxidative stress and lower chronic disease risk, understanding how preparation and storage conditions impact their availability is essential. In this study, cold brew coffees were prepared from roasted Arabica beans at 4 °C and 23 °C, with steeping periods up to 9 days. Total antioxidant capacity was measured using the Trolox Equivalent Antioxidant Capacity (TEAC) assay. Experimental results showed that significant amounts of antioxidant capacity were extracted from all coffee samples, and the TEAC values were independent of steeping temperature and duration. Future work should examine antioxidant solubility under varying water-to-coffee ratios to determine normalized solubility.

Abstract Name: Pragmatic Non-Alliance vs International Solidarity: A Study of Swedish Neutrality

In the opening of his memoirs, lifelong diplomat Gunnar Hägglöf wrote about how Swedish neutrality had originated not from a Swedish-born statesman or king, but from the Frenchman Jean Bernadotte—a former

Marshal under Napoleon—who had ascended to the Swedish throne as Karl XIV Johan; Hägglöf further noted that at first the policy was merely non-alliance, and only later developed into the longstanding policy of neutrality which Sweden would champion yet pursue in very pragmatic terms. Hägglöf’s insightful musing planted a question in my mind: when did Sweden’s foreign policy shift from non-alliance into a neutrality—one which would intertwine with domestic cultural identity, and define Sweden’s place on the world stage? To answer this question, I analyzed scholarly works covering the beats of modern Swedish diplomatic history (the Crimean War, World War 1, the Interwar Period, World War 2, and the Cold War) to compare and contrast the ways in which Sweden’s government acted—based on internal factors, such as public attitudes and cultural feelings, and external factors, such as the geopolitical environment and the degree of freedom of action or constricting pressure which Sweden faced therein—using primary sources for corroboration.

Abstract Name: Environmental Injustice: Connecting Cancer Alley Louisiana to the Democratic Republic of Congo

Louisiana’s Cancer Alley and the Democratic Republic of Congo (DRC) provide interconnected examples of ongoing environmental injustices. Cancer Alley is an 85-mile stretch, from Baton Rouge through the River Parishes to New Orleans, heavily polluted by petrochemical plants. This industrial pollution generates high rates of cancer and other health issues for the residents, who are predominantly African American. Additionally, recent U.S. federal action has increased the numbers of detainees being sent to U.S. Immigration and Customs Enforcement (ICE) facilities in or near Cancer Alley. The DRC is rich in cobalt, a core component of electronics, batteries, and petrochemical refining processes. Multiple social, political, and economic interests contribute to the exploitation of the Congolese laborers who are forced to mine cobalt in unsanitary, abusive conditions. This paper uses the theoretical lens of critical environmental justice to argue that these phenomena (Cancer Alley, ICE, and cobalt extraction) are interconnected. Through qualitative methods, including content analysis of activists’ publications and in-depth interviews with activists in Cancer Alley and the DRC, I examine the intersecting racial and colonial histories, human rights violations, and carceral systems within Cancer Alley and the DRC. I aim to establish international solidarity and accountability by promoting current activists and organizations actively fighting for justice.

Abstract Name: E.A.G.L.E. Autonomous Vehicle Vision: Edge-Aware Guidance for Lightweight Evaluation

Unmanned Aerial Vehicles (UAVs) require efficient real-time perception systems for autonomous navigation and target tracking, but continuously running high-resolution detection algorithms incurs significant computational costs that reduce flight time and system responsiveness. This work addresses this challenge by developing a biomimetic dual-mode perception system inspired by the double-fovea vision of birds of prey,

which use separate foveae for low-effort environmental scanning and high-precision target fixation. The proposed system implements two cooperative processing modes: a lightweight peripheral mode using for continuous wide-area surveillance with minimal computational load, and a high-precision foveal mode augmented with optical flow and Kalman filtering for active target tracking. These modes are coordinated through a three-state finite state machine that enables intelligent switching between low-power and high-fidelity perception based on real-time sensory input. The system includes a reacquisition state that prevents oscillatory behavior when targets drift near detection boundaries, mirroring the micro-corrective behaviors observed in biological vision systems. Implementation in Unity using Barracuda for ONNX model inference demonstrates real-time performance suitable for embedded UAV platforms. Results show that state-machine modulation dramatically reduces overall inference load during periods without salient targets while enabling rapid escalation to high-precision tracking when needed. This architecture offers a flexible framework for resource-constrained autonomous systems, demonstrating that biologically-derived strategies can be effectively integrated with modern deep learning pipelines. The approach is applicable beyond UAVs to any robotic system operating under fluctuating computational budgets, including legged robots, autonomous ground vehicles, and augmented reality systems requiring context-dependent allocation of visual processing resources.

Abstract Name: Reflection

Reflection explores humanity's overlooked relationship with the moon through an experimental bookbinding process that merges traditional craft with contemporary 3D printing technology. The central question driving this work asks: how can we create an object that embodies the moon's dependence on reflected light while encouraging viewers to reconsider celestial phenomena we encounter daily but rarely acknowledge? The project responds to a cultural paradox where we celebrate dramatic astronomical events like solar eclipses with collective awe, yet ignore the moon's nightly presence above us. This piece draws inspiration from the Japanese concept of tsukimi (moon-viewing) and the Romantic era's fascination with lunar symbolism, as well as contemporary concerns about our diminishing connection to natural cycles in an artificially-lit world. The work functions as both artist book and sculptural object, requiring viewer interaction to fully realize its meaning. Methodologically, this piece combines historical and emerging techniques. Each "page" was designed as a relief lithophane, a translucent image achieved through varied material thickness, and 3D printed in PLA filament on an Ender 3 printer. These plates were then handbound using Coptic-style multiple signature binding, allowing the book to stand independently and catch light from multiple angles. The construction deliberately requires the viewer to hold each page to a light source, mirroring how the moon requires sunlight to become visible. The most successful element is the experiential revelation, where viewers initially see subtle ghostly images, then the full image when holding pages to light. This mirrors my own renewed appreciation for looking up. Future work will explore color-filtered lithophanes to represent different lunar phenomena and experiment with alternative binding structures that allow more dynamic light interaction. This piece establishes a foundation for a broader series examining overlooked astronomical wonders through material processes.

Abstract Name: Variation in Annonacin Concentrations in Pawpaw (*Asimina triloba*) Leaves Across North Carolina: Therapeutic and Neurotoxic Implications

Pawpaw (*Asimina triloba*) is a native North American fruit tree that has recently grown in popularity as an alternative medicine due to its anticancer potential. Like other members of the Annonaceae family, pawpaw produces annonaceous acetogenins, secondary metabolites known for their cytotoxic capabilities. These bioactive molecules inhibit complex I of the mitochondrial respiratory chain, disrupting ATP production, inducing apoptosis in various cell types. However, studies have linked the chronic consumption of other fruits in the Annonaceae family to neurodegenerative issues like atypical parkinsonism. Because secondary metabolite concentrations vary geographically, pawpaw's large native range across the eastern United States could contribute to differences in bioactive contents, causing unpredictable health effects. This study aims to quantify annonacin, a cytotoxic acetogenin, from pawpaw leaves and investigate potential regional differences in concentrations across North Carolina. To determine geographical variation in acetogenin concentrations, leaf samples were collected from populations of pawpaw in the mountains and piedmont of North Carolina. Samples were air dried, extracted with 80% methanol and filtered. Using a rotary evaporator and lyophilizer, a crude extract was collected and injected into a HPLC-PDA system for analysis. The extraction yields from this procedure were between 7.45% and 10.15%, consistent with published values, indicating a viable extraction method. The quantification of annonacin concentrations via HPLC-PDA is ongoing, and results will be compared with concentrations to known bioactivity ranges, evaluating the geographic variation in the neurotoxicity of our samples. With a rise in popularity of natural medicines, this research will provide insight into the potential health risks of the unregulated use of plants, such as pawpaw, for medicinal purposes.

Abstract Name: Affordable Hand Prosthesis Utilizing Common and Accessible Components

Assistive and prosthetic devices can be prohibitively expensive, limiting those below the poverty line. However, for many cases costly prosthetics are unnecessary to assist in one's quality of life. Our research presents an affordable alternative hand prosthesis for individuals missing any range of phalanges, while retaining the metacarpal region. To do so, the e-NABLE Statics Team engineered a general prosthetic finger that can be altered in length and ring size to be fitted to the client's hand as well as an adaptable hand. Components of the finger and hand include: Polylactic Acid (PLA), Thermoplastic polyurethane (TPU), fishing line, bungee cord, and gloves. The PLA filament is used to print the main finger structure, while TPU is used for the base attachment to the glove. The fingers are controlled through a mechanical tendon system, utilizing tensioned fishing line for contraction and bungee cord for retraction, all while being articulated with wrist movement. To adapt this idea to a whole hand, we engineered a base made of PLA and TPU, which is connected to a glove for optimal comfort. This hand prosthesis can be an optimal alternative for those with minor disabilities in need of an assistive device.

Abstract Name: Detecting Exoplanets in a Light Polluted Environment

Light pollution has become increasingly dominant as the developed world continues to expand, presenting greater challenges for ground-based astronomy (GBA) even in the most isolated observatories. The capabilities and limitations of conducting astronomical research in a light-polluted environment are ever-changing, and this project examines the feasibility of GBA in such an environment with an observatory-class telescope. This research was dedicated to the detection of extrasolar planets transiting across their host stars via a light-curve, in which the star's luminosity periodically dips as the planet crosses in front of it, blocking a portion of its light. The research focused on stars with known exoplanets where the parameters (area ratios, magnitude, etc.) were known, as well as the time of planetary transit. The method used to discern a star's periodic depression was differential photometry, in which the star's relative flux was compared to numerous others around it whose fluxes were assumed constant. Six systems with varying parameters were studied in which the acquisition of a light-curve, along with the quality of that light-curve, were compared to those of other systems to quantify the limits of the telescope under the conditions of skyglow. Data acquired was compared to exoplanet databases to evaluate the effect of light pollution on the accuracy of the data. Over the course of the research, two light-curves resulted where the transit was clearly distinguishable. The comparison of our data showed that, for successful transit detections, the transit depths were close to prediction, but transit durations were less precise. The successful acquisition of these light-curves presents the capabilities of scientific research and astronomy education via GBA, even at an amateur level, whereas inaccuracies or failure to detect some light-curves demonstrates the challenging effects of light pollution in an urban environment.

Abstract Name: Statistical and Synoptic Patterns of Drought Busts Associated with Atmospheric Rivers in the Northeast U.S.

Climatological drought in the Northeast U.S. is an important thing to understand and predict because of the high population density, tourism dependent economies (like skiing), and the drinking water supply (Agel et al. 2025). This study aims to observe the patterns associated with drought in the Northeast for the period spanning 1988 to 2017, focusing on the relationship between drought and atmospheric rivers (ARs). A similar study was conducted along the West Coast by Dettinger (2013) where it was found that between 33% and 74% of droughts were busted by ARs. To study this in the Northeast, the Palmer Drought Severity Index (PDSI) was used to indicate and categorize drought for the region. AR data was obtained from a 30-year climatology done by Kaminski et al. (2023). Overall, there are very clear relationships between PDSI and ARs that indicate a causal relationship between ARs and the cessation of drought in the Northeast. There is a positive relationship between the positive change in monthly PDSI and the percentage of monthly AR hours and AR-related precipitation (ARP). For the bust months specifically, the coastal region received more ARP. Despite having average to low percentages of AR hours, the bust months generally have high percentages of ARP. As for the synoptic conditions, the bust months feature zonal flow and a persistent trough

over the Great Lakes region that is favorable for a high frequency of surface low pressure systems, which provides a high amount of IVT in the Northeast for bust months.

Abstract Name: Addressing Postpartum Depression Through Nursing Interventions: A Synthesis of Evidence-Based Approaches

AbstractBackground: Postpartum depression (PPD) affects up to one in five mothers and can impair maternal functioning, infant bonding, and overall family well-being. Many postpartum women decline pharmacologic therapy due to breastfeeding concerns, stigma, or personal preference, increasing the need for accessible, non-pharmacological nursing interventions. Evidence supports Cognitive-Behavioral Therapy (CBT) strategies and technology-based peer-support programs as effective, nurse-facilitated approaches to improve maternal mental health outcomes. **Aim:** This project aims to evaluate the impact of two nurse-facilitated interventions – CBT-informed nursing strategies and technology-based peer-support programs in reducing postpartum depression symptoms compared to standard postpartum care. **Method:** A two-part intervention model focused on CBT techniques and technology-based peer-support. CBT-informed nursing care would include helping mothers identify negative thought patterns, teaching cognitive reframing, reinforcing positive coping strategies, and integrating brief CBT-style check-ins during postpartum visits. For technology-based peer-support, mothers will be connected with trained peer supporters through secure digital platforms, monitor engagement, and provide ongoing follow-up for safety and emotional support. Both components would be paired with routine EPDS screening, education, therapeutic communication, and timely referrals when needed. This model reflects feasible, evidence-based interventions aligned with nursing scope and current literature. **Conclusion:** CBT-informed nursing strategies and technology-based peer-support programs represent accessible, non-pharmacologic interventions that nurses can realistically integrate into postpartum care. These approaches strengthen coping, reduce depressive symptoms, and increase social support, ultimately promoting maternal mental health and positive family outcomes. Findings highlight the importance of expanding nurse-facilitated mental-health interventions within postpartum settings. **Keywords:** Postpartum depression, nursing interventions, cognitive-behavioral therapy, peer support, maternal mental health.

Abstract Name: The Effects of Polyamines on CD4+ T Cell Differentiation

Systemic Lupus Erythematosus (SLE) is characterized by an overactive immune system attacking the host body. Th17 cells, a subset of CD4+ helper T cells, are one such hyperactive immune cell associated with many autoimmune diseases including SLE. The primary role of the Th17 cell is to coordinate immune responses to bacterial and fungal infections through the production of IL-17, a pro-inflammatory cytokine; however, aberrantly overactive Th17 cells produce excessive IL-17 and are associated with SLE symptoms.

Our research focuses on the effects polyamines have on CD4+ T cell differentiation to better understand this hyperactivity. Polyamines are long-branched alkylamines that are known to affect the differentiation of many cell types, including CD4+ T cells, through mechanisms including post-translational modification, metabolic modulation, and epigenetic regulation. Our research further explores the link between polyamines and T cell differentiation through direct control of polyamine concentrations within naive CD4+ cells during Th17 polarization in vitro. Splenocytes were collected from murine spleens, and CD4+ T cells were magnetically isolated. In addition to Th17 polarization cytokines, CD4+ T cells were cultured under polyamine addition or depletion for five days. Polyamine addition included the three essential polyamines: putrescine, spermidine, and spermine, as well as their precursor ornithine. Polyamine depleting conditions were established via treatment with ivosipemin or difluoromethylornithine (DFMO), two drugs known to deplete polyamines. Th17 polarization was confirmed by measuring IL-17A production by RT-qPCR, flow cytometry, and ELISA. Our findings suggest that the presence of polyamines promotes differentiation into the Th17 cell type. This result, while limited by the in vitro nature of the study, may implicate a broad role for polyamines in autoimmunity and could be helpful in future research into the treatment of SLE.

Abstract Name: The Research Deficit and Expert Disagreement Regarding Music Selection for Psychedelic Assisted Therapy

Prior research has determined that music plays a central role in psychedelic assisted therapy (PAT). There is a general consensus of the importance of music during PAT, so how are guides and researchers choosing this music? In my recently published paper, The Research Deficit and Expert Disagreement Regarding Music Selection for Psychedelic Assisted Therapy, I hold that it seems unreasonable for anyone at this point to claim guidelines for musical selection for PAT are firmly based on scientific evidence. With only three empirical studies published to date that directly investigate which type of music might best support PAT, each with important limitations, and disagreement amongst the experts in this field, I highlight the paucity of research and make suggestions of priorities for future studies. To summarize, there is a lack of research in this area and unclear guidelines due to expert disagreement. Because music has potential to greatly improve and drive the PAT process entirely, without empirically-based music selection, we risk neglecting one of its most important therapeutic elements. Additionally, I am currently conducting a follow up survey study that is investigating practitioner and patient experience and opinions regarding music selection. I am hopeful to have my data back and analyzed by January to potentially speak on as well. Thank you for your consideration

Abstract Name: The effect of accessible Montessori Education on political awareness and engagement in youth: a case study of la Scuola Primaria Montessori, Italy

Neoliberal economic policies have led to rising income inequality, limited access to critical resources, environmental degradation and growing political unrest. Young people have the most to lose if the current

trends continue, yet the very same social order youth seek to change robs them of the tools most necessary to do so. Compulsory education guided by the so-called 'banking model' trains youth to submit to authority and accept the truths offered to them by those in power. Critical pedagogies, such as the method developed by Maria Montessori in Italy in the early 20th century, have the potential to disrupt this pacification of youth if made universally accessible. The majority of institutions practicing the Montessori method cater only to the elite, but in Perugia, Italy, a public primary school seeks to make Montessori education available to middle and working class children in the city. Thus, I have elected to conduct this qualitative case study informed by critical pedagogy at la Scuola Primaria Montessori di Perugia. My research goal is to identify the theories and practices applied at the aforementioned primary school that suppress or foster the development of politically aware, engaged and empowered youth. I carried out semi-structured interviews with educators employed at the Scuola Primaria Montessori di Perugia, and spent three months collecting data via participant observation of daily activities in six classrooms of first to fifth graders in 2025. Findings indicate that a lack of adequate physical space, funding and standardized teacher training, the prevalence of normative bias and the imposition of national curriculum criteria foster an educational environment inhospitable to the Montessori methods' foundational principle of student autonomy and unsupportive of the cultivation of youth capacity to intervene in and transform their reality. These insights could inform policymakers and administrators aiming to institute critical methodologies in public education.

Abstract Name: Desensitization to Sexual Violence and Paraphilic Disorders: TikTok True Crime Content and Passive Hybristophilia-like Social Phenomena in Women Ages 18-35

Social media has been a way to share a user's thoughts and opinions about topics of the user's choosing. After the merger of TikTok and Musically from 2017 to 2018, TikTok became one of the top five most commonly used social media platforms in the world. TikTok's algorithm generates videos mainly based on the user's previous video and comment section interactions, potentially causing an echo chamber effect and leading to the intensification of societally stigmatized viewpoints and interests, like passive hybristophilia. A subspace on TikTok where passive hybristophilia can be witnessed is the True Crime TikTok community due to some of the community's glamorization and heavy editing of the criminal and the criminal's act. Previous research has explored the common themes presented in TikToks displaying hybristophilia-like qualities; however, the research did not explore how desensitization can lead to the creation of the examined themes. This study investigated the association between the desensitization to sexual violence driven by the True Crime TikTok community on women, aged 18-35, and the development of passive hybristophilia-like social phenomena among online audiences. The study examined TikToks from the True Crime TikTok community that displayed hybristophilia-like characteristics to determine if the consumption of hybristophilic-content can lead to a group-think mindset that is desensitized and less empathetic due to the characterization of the highlighted criminal.

Abstract Name: Chemotherapy-Induced Peripheral Neuropathy Leads to Long-Term Sensory Deficits in Pediatric Oncology Survivors

Chemotherapy-induced peripheral neuropathy (CIPN), the degeneration of nerves outside the central nervous system as a result of treatment, is a side effect of vincristine, a common chemotherapy drug prescribed to children with leukemia. Vincristine disrupts the formation of microtubules in cells, preventing cell division. This causes changes in the neuronal cytoskeleton, which can injure the axons, leading to impaired transmission along nerve fibers. The goal of this study was to determine if a difference was present between the nerve function of pediatric cancer survivors treated with vincristine (on average, 61.4 months post-last chemotherapy treatment) to controls never given vincristine, via pairs matched by sex and age. Three sensitivity tests were conducted (n=16 pediatric cancer survivors and 16 controls): 1) distinguishing between the blunt and sharpened ends of a Medipin; 2) threshold detection of touch with fine monofilaments (similar to fishing line); and 3) threshold detection of vibration applied to the skin. Analysis with t-tests showed statistically significant deficiency in thresholds for light touch and vibration on the lower extremities of the cancer survivors ($p < 0.05$), but not on the upper, suggesting that the longer axons in the legs may be more susceptible to long-term damage. These findings demonstrate there may be a correlation between receiving vincristine and sustained nerve damage in cancer survivors, particularly in the lower limbs. Further research into the axonal differences between upper and lower limb nerves that explains the discrepancy between the deficiencies, as well as reviewing surveys from cancer survivors to assess the clinical relevance of these results is needed.

Abstract Name: Clementine Hunter's Artwork: Struggles of the American South

Clementine Hunter, a self-taught artist, lived on the Melrose Plantation in Natchitoches, Louisiana as a sharecropper from 1902-1988. Photos from the Farm Security Administration, an agency dedicated to photographing farmer's struggles, provide insight about what life may have been like for her on the plantation. As Hunter began to paint, her artwork revealed representations of hardships that African Americans endured after slavery, the role of women in society, and the nature of religion. An analysis of life histories collected in the Federal Writer's Project, an initiative to conduct interviews of everyday Americans throughout the country in the early 1940s, and FSA photographs offer a rich cultural context to understanding the inspiration behind her artwork. An analysis of her paintings, which some critics have called "primitive" due to the use of scrap paint and brushes, will reveal how her work is a unique portrayal of the struggles of African Americans in the south.

Abstract Name: Silk following behavior and mate competition in male Northern crab spiders *Mecaphesa asperata*

All spiders produce silk draglines as they move through the environment. This material may convey important information about spider identity including age, sex, and mating status. Silk could also be used by males to locate prospective mates or rival males. The Northern crab spider *Mecaphesa asperata*, is common in goldenrod fields, feeding on insects that visit blooming flowers. Using artificial flowers as Y-mazes, we measured the propensity of adult male spiders to contact and climb one of two stems containing silk deposited from different types of conspecific spiders. Six y-maze choice combinations were tested: 1) silk from an adult male v. silk-free control, 2) an adult female v. control, 3) a subadult female v. control, 4) a subadult female v. adult female, 5) an adult female v. adult female followed by an adult male's silk, or 6) a double control lacking silk. Preliminary results suggest that males show strong initial attraction to any conspecific silk (sericophily), climbing higher on silk-laden stems compared to control stems. For some behavioral measures, males showed a stronger preference for stems with subadult female silk compared to silk laid by other ages and sexes. Males may prefer subadult females that allow for pre-maturation mate guarding to avoid sperm competition since first-mated male spiders tend to fertilize the majority of eggs. Stems containing adult female silk followed by male silk showed no difference in attractiveness than female silk alone, suggesting that male silk is used by rival males as a cue for female presence, rather than a deterrent for male competitors.

Abstract Name: Using a Student-Made Horn Radio Telescope to Map the Milky Way Galaxy

This research project proposed a goal of constructing a horn radio telescope to investigate and determine the structure of the Milky Way Galaxy. This project stemmed from the NSF-funded workshop "Science and Technology Applied to Radio Signals" held at Concord University in July of 2025. The student assistant who participated in this workshop was able to build a radio horn telescope, which was used in this experiment. These radio telescopes are used to detect radiation emitted from hydrogen atoms undergoing spin flip transitions at a frequency of 1420.41 MHz. Spectral data was gathered via conduction of galactic scans along the galactic equator. Measuring Doppler shifts in the spectral peak positions enabled the determination of the galactic velocities along the galactic equator. These velocities were used to construct a map of the spiral arms in the Milky Way Galaxy. This conducted research has proven that student-built horn radio telescopes can contribute to the scientific understanding of our galaxy's structure and dynamic behavior. This project provides the opportunity for undergraduate students to engage in STEM experiences, which can allow for a better understanding of the science behind West Virginia's Green Bank Observatory in order to advance students' education.

Abstract Name: AI and PR Practitioners

How PR Practitioners Talk About AI: Topic Modeling and Emerging Patterns on X Artificial intelligence (AI) is transforming communication work in profound ways; however, there is limited research on how public relations (PR) practitioners publicly discuss these changes in real-time. Previous studies highlight both the potential of AI to improve efficiency and creativity (Lai & Levy, 2023) and the challenges it introduces, including job insecurity (Petropoulos et al., 2024), ethical and fairness concerns (Haque et al., 2022), and questions about trust in automated decision-making (Lee & See, 2004). Scholars have also underscored the broader societal implications of AI, such as environmental and equity considerations that communication professionals must navigate (Heavens et al., 2025; Sheridan et al., 2025). Despite these important contributions, little is known about how PR practitioners themselves describe AI in their everyday professional discourse. This work-in-progress project examines how PR practitioners talk about AI on X. To address this gap, we are collecting a large dataset of tweets from verified or professionally identified PR accounts using AI-related and PR-related keywords. Accounts are verified through bio descriptions that contain terms such as “public relations,” “communications,” “PRSA,” or “CIPR,” ensuring the dataset reflects actual practitioners. Each tweet includes the post text, author metadata, timestamps, and engagement metrics, and will be analyzed in R using computational methods. Our next phase involves topic modeling and sentiment analysis to identify the main narratives practitioners use when discussing AI. Based on previous scholarship, we expect to observe conversations that reflect optimism, uncertainty, ethical tension, and questions about professional identity (Haque et al., 2022; Lai & Levy, 2023; Lee & See, 2004; Petropoulos et al., 2024). By the time of the conference, we anticipate presenting early visualizations and thematic patterns that illustrate how PR professionals are collectively navigating the opportunities and risks associated with AI in their daily work.

Abstract Name: Hidden Dangers: Analysis of Trace Metals within Medicinal Herbs and Spices in the United States

Plants uptake valuable nutrients, but due to environmental conditions such as exposure to industrial pollutants and the effects of climate change, the accumulation of toxic metals is increasing. Recent studies in Asia and the Middle East show elevated levels of lead and mercury in herbs and spices used in traditional medicines. This may be due to two factors: 1) lack of regulation, and 2) herbs may be hyperaccumulators of metals. Interestingly, limited research on traditional herbs has been done in the US, specifically in Native American communities. The proposed research will analyze the metal accumulation in numerous medicinal herb and spice samples from six states (NM, OK, SD, MA, NC, ID) using X-ray fluorescence and inductively coupled plasma optical emission spectroscopies to generate a consensus survey documenting metal concentrations in select herbs. The specific metals quantified will be cadmium, chromium, copper, lead, mercury, and zinc. Analyses will be carried out on commercially packaged goods, pre-processed material, and herbs grown in metal-contaminated soil, and the following herbs will be selected from each region: basil, coriander, echinacea, elderberry, juniper berry, lavender, rosemary, sage, and yarrow. Preliminary results for OK

samples indicate that toxic metals are below EPA guidelines. Analysis for the remaining regions is expected to be completed late Spring 2026.

Abstract Name: A Data-Driven Approach to Evaluating Posture and Self-Efficacy in First-Time Mobility Scooter Drivers

Individuals with mobility limitations increasingly use Motorized Mobility Scooters (MMS), yet safety concerns for both drivers and pedestrians remain. This study introduces a data-driven approach to evaluating MMS driver safety by combining human pose estimation with self-efficacy assessment. By analyzing posture and movement patterns alongside drivers' perceptions of their own ability, we aim to identify risk factors and inform interventions that enhance safety outcomes. Our research involves 42 participants, each completing a self-efficacy survey and undergoing posture analysis during their initial MMS experience. Preliminary findings suggest that posture and body positioning are critical to maintaining stability and control, while self-efficacy scores provide insight into drivers' confidence and perceived proficiency. Leveraging advanced computer vision algorithms, we capture real-time pose data to quantify drivers' movements and correlate these with survey responses. This integrated approach allows us to examine both the physical and psychological dimensions of scooter operation. Although data collection and analysis are ongoing, early results highlight the potential of combining human pose estimation with self-efficacy measures to generate a comprehensive understanding of MMS driver safety. Insights from this study may inform evidence-based strategies for improving scooter design, training programs, and overall safety for users and the communities they navigate. By focusing on first-time drivers, our work sheds light on the challenges of initial MMS use and provides a foundation for interventions that support safer adoption of mobility technology.

Abstract Name: Associations Between Broader Autism Phenotype Domains and Well-being in College Students.

The Broader Autism Phenotype Questionnaire (BAPQ) measures subclinical autism-related traits in three domains: social aloofness, pragmatic language differences, and rigidity. Although higher levels of overall BAP have been linked to mental health and social adjustment in college students, domain-specific associations are not fully understood. This study examines associations between each BAPQ domain and indicators of mental and social well-being. Identifying patterns across BAP domains could explain how autistic-like features are linked to emotional discomfort and social interactions, allowing for inclusive prevention and intervention strategies in university populations. Survey data were collected online from 621 students ($M_{age}=19.42$, $SD=1.21$; 74.7% female; 75% Caucasian; 76.7% in their first two years of college) at two U.S. universities, one in the northeast and one in the northwest. In addition to the BAP-Q, participants completed self-report measures of anxiety symptoms (GAD-7), depression symptoms (PHQ-9), college belongingness (SSFS), and rejection sensitivity (RSS). Higher anxiety symptoms were associated with higher aloofness, pragmatic language differences, and rigidity (r range= 0.255–0.411, $p \leq .001$). Higher

depressive symptoms were also associated with all three BAP traits (r range= 0.273-0.462, $p < .001$). Higher rejection sensitivity was associated with higher aloofness, language differences, and rigidity (r range= 0.264–0.346, $p < .001$). Higher college belongingness was associated with lower social aloofness, language differences, and rigidity (r range= -0.203 to -0.433, $p < .001$). Covariates were university/site, sex, gender, and sexual orientation. BAP domains are linked to markers of developmentally salient wellbeing – mental and social health – in emerging adults. Findings support the utility of conceptualizing autistic traits as existing along a continuum rather than a binary diagnosis, suggesting that support services could be scaled to meet varying levels of need across the BAP rather than limited to those with formal autism diagnoses.

Abstract Name: Decoding Semantic Information from the Brain

Language-based brain-computer interfaces (BCIs) have, in recent years, shown promise in helping facilitate communication for those who are otherwise unable to do so due to various factors, such as motor impairment, paralysis, or communication disorders. However, most BCIs rely solely on activation in areas that process sensorimotor information to decode words and do not take into account the semantic information associated with each word: that is, information about a word's meaning. The objective of this project is to investigate methods to decode various types of semantic information from intracranial EEG recordings. Taxonomic semantic information is organized hierarchically (e.g., a dog and a cat are both mammals, so would be grouped under the same taxonomic category), while thematic semantic information is organized based on co-occurrence in a specific context (e.g., a nurse and a syringe both appear in a medical context, so would be grouped in the same thematic category). We have two aims for our study: first, to decode taxonomic semantic information by incorporating semantic models into our signal-processing code; and second, to establish if and how thematic semantic information can be cross-coded alongside taxonomic information. By examining these distinct means of decoding semantic information, we hope to find a way to integrate semantic decoding with existing phonetic or sensorimotor decodes used by other labs.

Abstract Name: Bioactive Metabolites in Ganoderma Species and Their Anticancer Mechanisms of Action

The genus *Ganoderma* has been extensively studied for its medicinal and therapeutic potential in cancer prevention and treatment, with *G. lucidum* among the top-studied species. From 2010-2015, researchers have made significant advances in characterizing the structural diversity of *Ganoderma* mycochemicals, including polysaccharides, triterpenoids, phenols, and other secondary metabolites linked to anti-cancer activity.

Chromatographic methods (HPLC, LC-MS, GC-MS) enabled the separation of complex *Ganoderma* extracts into individual metabolites, while spectroscopic techniques (NMR, MS/MS) provided insight into the structure–function relationships of these bioactive molecules. Mechanistic studies of *Ganoderma*-derived compounds have revealed their capacity to modulate cancer activity through apoptosis induction, cell cycle regulation, angiogenesis inhibition, immunomodulation, and oxidative stress reduction. While cytotoxic benefits of *Ganoderma* seem promising, a key issue lies in the standardization and reproducibility for pharmacological application. Chemical composition varies markedly across species, strains, and environmental conditions; many metabolites also exhibit poor solubility, stability, and bioavailability. Future studies should combine gene sequencing with metabolomics to understand why different *Ganoderma* species produce distinct bioactive compounds and to generate reproducible preclinical data strong enough to justify any later movement toward clinical testing. Addressing these challenges will be essential to realize the full oncologic potential of *Ganoderma*-derived therapeutics.

Abstract Name: Comparative Genomics Across *Ganoderma* Species to Identify Secondary Metabolite Clusters with Cytotoxic Properties

Fungi in the genus *Ganoderma* have been widely studied in Chinese culture for their medicinal properties and promoting overall health and longevity. Our prior work on eight *Ganoderma* species showed that they contain Secondary Metabolite Clusters (SMCs) that code for multiple terpenes, betalactones, and ribosomally synthesized and post-translationally modified peptides (RiPPs). These compounds are well known for their cytotoxic and anticancer potential. Using the bioinformatics platform antiSMASH1, we previously identified and annotated the specific SMCs within these genomes that are predicted to produce such bioactive metabolites. To test the results obtained from the bioinformatics analysis, fungal extracts were prepared from *G. lucidum* and *G. zonatum* by air-drying and powdering the mushroom fruiting bodies, mixing them with 95% ethanol, followed by lyophilization. Different dilutions of these extracts were used for proliferation assays on two cancer stem cell (CSC) models, i.e. patient-derived glioma stem cells (GSCs); PN84 and GSC17 to assess the cytotoxicity potential of the fungal compounds. Proliferation was measured at 24, 48, and 72 hours, and survival analysis showed significant reductions in PN84 viability by 72 hours at 100 ppm for both extracts. Comparative transcriptomic analysis of both the fungi and the treated cancer cells will define the pathways/gene-expression changes associated with metabolite production and cytotoxic response, with qRT-PCR used for targeted validation. These findings provide experimental support for the anticancer potential of *Ganoderma* metabolites and justify continued investigation of these natural products for pharmacological and nutritional applications.

Abstract Name: Elucidating the effect of Phthalates Plasticizer Family on Kaposi's Sarcoma associated Herpesvirus Infection

Kaposi's Sarcoma-associated Herpesvirus (KSHV) is an oncogenic virus that causes Kaposi's Sarcoma (KS), the predominant cancer in HIV infected untreated individuals with no known cure. KSHV has two stages: latency (low viral gene expression and no virions) and lytic replication (full viral gene expression and virion production). Plasticizers are additives found in nearly all flexible plastics. Exposure to phthalic acid-derived plasticizers (PPs), di(2-ethylhexyl) phthalate (DEHP), its metabolite Mono-(2-ethylhexyl) phthalate (MEHP) and Diisononyl phthalate (DINP), increases infectivity in Cocksackie B virus and Dengue viruses. As such, non-phthalate plasticizers (NPPs), like Dioctyl terephthalate (DEHT) and its metabolite terephthalic acid (TPA) are emerging PP replacements. We hypothesize that PPs will cause differential gene expression in KSHV-infected cells and affect virus production, while NPPs will not. To test this, we utilized iSLK.BAC16 cells, which maintain the KSHV genome, constitutively expresses GFP, and can be induced to lytic replication upon Dox treatment. We measured KSHV viral gene expression and viral production after pre-treatment with PPs (DEHP, MEHP, or DINP) and NPPs (DEHT and TPA) for 24hrs and then induced lytic replication for 48hrs. We extracted RNA to measure the expression of an early lytic gene (ORF59) and a late lytic gene (K8.1) via RT-qPCR, collected the supernatant to titer for virus production, and extracted DNA to compare the number of viral genome copies after lytic replication. Preliminary data show that DEHP significantly decreases late lytic gene expression and reduces infectious virion production. Similarly, DINP and MEHP decreased infectious virion production. Current work will characterize DINP and MEHP's effect on viral gene expression and NPPs effects on KSHV. Future work will elucidate the mechanism by which PP chemicals inhibit KSHV infection. Understanding how phthalates disrupt KSHV and host cells may reveal therapeutic targets, while highlighting plasticizer exposure as a toxicology concern for viral infections.

Abstract Name: The Economic Impact of Organic Farming in India

This paper explores the relationship between farming methods and agricultural wages in India. While conventional methods are associated with increased yields, organic farming is more ecologically sustainable and produces healthier food for consumers. The exact economic effects of both methods continue to be debated, as it is unclear if the increased input costs of conventional farming are offset by the lower yields of organic farming. State investment in agriculture also plays a key role in this relationship, as it is often linked with lowering food prices and rising incomes. This paper uses state level data to examine how trends in agriculture, agricultural wages, and state investment in agriculture in India have changed between 1980 and 2022. It then uses correlation tests to measure the strength of the relationship between both farming method and state investment and average agricultural wages. Finally, the paper uses multiple regressions to measure the combined effects of farming methods and state investment in agriculture on agricultural wages. From this analysis, the paper finds that, though the consumption of organic fertilizers has generally increased since the introduction of organic farming in India, several states show recent downturns in this consumption. Concurrently, chemical fertilizer consumption trends generally increase over time, even after the introduction of organic methods. As compared to these organic methods, this paper finds that the use of conventional methods is more closely, positively correlated with agricultural wages at the state level. However, state investment is also most strongly correlated with increasing wages across both farming methods. The findings of this paper have broader implications in examining the economic viability of agriculture in India and beyond, though it leaves room for further study, particularly in incorporating the ecological costs of conventional methods in a long-term economic analysis.

Abstract Name: Design and Implementation of a Multipurpose Automation Control System for Sorting and Material Handling

This project investigates whether a low-cost, vision-guided robotic automation system can accurately sort and manipulate objects using a unified platform built around the Dobot MG400, OpenCV-based machine vision, and PLC-controlled actuation. The goal is to create an accessible training system that allows undergraduate students to gain hands-on experience with industrial automation workflows that are typically too expensive for university labs to replicate. Automation systems that integrate robotic motion, machine vision, and PLC coordination are central to modern manufacturing, yet most educational environments lack affordable versions of these technologies. Existing research often examines robotic sorting or PLC-based control separately, but rarely as a single low-cost system. By merging a real-time camera pipeline, robotic motion control, and synchronized hardware actuation, this project provides a practical model that fills a gap between academic instruction and industrial practice. The methodology centers on three coordinated subsystems: a Python/OpenCV module that performs object detection and coordinate extraction; a Lua-based control layer on the MG400 that executes motion sequences; and a PLC-driven actuation system that handles suction, gripping, and conveyor timing. Object data flows from the vision module to the robot through Modbus communication, while the PLC manages end-effector behavior and conveyor movement to complete the sorting cycle. The expected outcome is a fully functional, autonomous sorting system capable of identifying objects by color, shape, or size and accurately placing them through synchronized mechanical and electronic operations. These results will be discussed in the context of engineering education, demonstrating how low-cost automation platforms can provide meaningful preparation for Industry 4.0 environments and expand access to robotics, vision systems, and industrial communication training.

Abstract Name: From Risk to Flourishing: Rethinking AI-Driven Marketing in Digital Media Environments

This study examines how core dimensions of human flourishing, mental health, happiness, and close social relationships, are represented in scholarly research on artificial intelligence (AI) and digital media. Using a bibliometric analysis of 2,839 scholarly journal articles, we map how these technologies are framed in relation to flourishing outcomes. The findings reveal a dominant risk-oriented lens, with literature emphasizing depression, anxiety, stress, and addiction. In contrast, positive indicators such as happiness and

close social relationships remain underrepresented and weakly integrated. Although AI research is expanding rapidly, it has largely developed in parallel with, rather than integrated with, flourishing-based perspectives. Given that marketing plays a central role in shaping digital experiences through algorithmic systems, this imbalance presents both concern and opportunity. We advocate for integrating a flourishing-oriented framework into digital marketing strategy, arguing that such an approach may strengthen brand trust, loyalty, and long-term competitive advantage

Abstract Name: Assessing Student Buying Behavior: The Role of Marketing Strategies

I attend Life University, a private institution with a growing and diverse student body known for its specialization in Chiropractic education. As an international student, I quickly noticed that many universities in the U.S. offer a wider range of products and services in their campus stores than what is currently available at Life U. This realization prompted me to look more closely at the purchasing data from at our university shop to understand what students actually buy and where there may be gaps in the current offerings. As part of the research project, I examined patterns such as when students shop most often, which items are bought regularly, how purchasing changes during different times of the quarter, and whether certain student groups show different preferences. Instead of assuming what students want, the goal was to see what their behavior shows. Early observations suggested that students tend to focus on convenience, affordable everyday items, and products that match academic pressures like exam periods. Interest in school-branded merchandise also increases around major campus events. Based on these findings, the project proposes a selection of new product categories, small service improvements, and marketing approaches that feel more aligned with student routines (e.g. offering practical bundles, expanding wellness-related items, or running short-term promotions at times when students are most likely to need them). The overall aim of the research is to show how data-based decisions can help the campus store better support student life while making its operations more effective. By connecting actual purchasing behavior with realistic marketing ideas, the store could better meet the needs of the academic community preparing for demanding academic and professional paths.

Abstract Name: Nitrogen Dioxide and Ozone Trends in Major Cities in the U. S. Cities During 2024 Using Pandora Spectrometry

Nitrogen oxides ($\text{NO}_x = \text{NO} + \text{NO}_2$) are formed through the emission of fossil-fuel combustion and are subsequently oxidized in the atmosphere to form nitrogen dioxide (NO_2). Ozone (O_3) is a pollutant primarily formed through photochemical relations involving volatile organic compounds (VOCs), sunlight, and

nitrogen oxides. While O₃ in the stratosphere plays a critical protective role by absorbing ultraviolet radiation, elevated levels of NO₂ and O₃ near the surface are detrimental to our health and air quality. Because NO₂ is a key precursor to the formation of ozone, the two often exhibit an inverse relationship. This trend varies seasonally and is influenced by sunlight intensity and meteorological conditions. This research investigates NO₂ and O₃ trends during 2024 across multiple major cities in the United States to evaluate how changes in air quality reflect atmospheric process. The data was taken from the Pandonia Global Network, a collaboration between NASA & European Space Agency (ESA), through the collection of hundreds of spectrometers across the globe. These instruments provide high-resolution, real-time measurements that were processed and analyzed using Python-based data analysis techniques.

Abstract Name: Developing a Treatment for Chronic Pain Using Vagus Nerve Stimulation and Pharmacologics

Radial nerve injury (RNI) often results in the development of allodynia or hypersensitivity to touch, which leads to chronic pain. Vagus Nerve Stimulation (VNS) has been successful in improving sensory perception after loss of tactile sensation. However, earlier studies that administered VNS to treat chronic allodynia have failed to restore the pre-injury perception. Recent findings suggest that VNS, which modulates neurotransmitter release, combined with beta-adrenoceptor blocking drugs, improves rehabilitative outcomes. The goal of this study is to test whether Beta-Blockers, combined with VNS, can be used to enhance recovery in cases of allodynia. We hypothesize that VNS combined with beta-blockers and rehabilitation will restore typical sensory thresholds and paw preference. To test this, we performed the radial nerve injury (RNI) in order to induce allodynia. The animals were then organized into 4 sets of groups that underwent rehabilitative therapy paired with and without VNS, and were administered either the beta-blocker propranolol or a vehicle injection. To assess sensory improvement, an automated von Frey assessment was conducted throughout the experiment to observe mechanosensory withdrawal thresholds. To evaluate paw preference, rats were placed in an acrylic cylinder, and their spontaneous paw touches to the wall were counted. As expected, rats in our preliminary findings had a significant decrease in the withdrawal thresholds and in the use of the injured paw in exploratory behavior immediately after the injury. Surprisingly, neither VNS alone nor VNS paired with propranolol during rehabilitation improved the outcomes. Taken together, VNS did not restore sensory function in rats with allodynia, nor did manipulating the neuromodulatory mechanism involved. Our next steps are to further explore additional nociceptive mechanisms that are preventing recovery and causing hypersensitivity. Findings from this study may provide insight into future neurorehabilitative sensory therapies and pave the way for a fundamentally novel strategy for treating chronic pain.

Abstract Name: Connecting Pesticide Overuse and Malaria in Uganda: A Public Health Perspective

Malnutrition and malaria severely burden public health systems in low-income countries, causing nearly 10 million annual deaths. These concerns are also worsened by climate change through increased food security challenges, changing weather conditions, and increased use of agricultural chemicals, like pesticides. Previous research has connected pesticide use to nutrient sequestering in soils and nutrient deficiencies in crops. In East Africa, a largely agrarian region, micronutrient malnourishment has been identified as a critical issue affecting individual health and educational/economic productivity due to decreased immune function. This is especially dangerous during concurrence with malaria as the parasite is able to evade the immune system without a robust response. The current research seeks to extend what is known about pesticides, malnutrition, and malaria to The Republic of Uganda. To do this, a survey was conducted by an interdisciplinary research team in the Kibale region to gain a better understanding of agricultural practices and pesticide use. Additionally, soil and cassava samples were collected from the Rwenzori region and underwent analysis for nutrient sequestering and deficiency. Further, households around the Rwenzori region were surveyed about rates of illness or death and children's anthropometric measurements were obtained. Overall, the survey results will provide information about pesticide use and will be combined with soil/cassava data to gain understanding about current nutrient deficiencies. This will then be combined with anthropometric data to observe correlations between nutrient deficient crops and malnutrition/malaria rates. Preliminary results suggest that climate and pest conditions in Uganda are indeed leading to increased pesticide use and initial soil and cassava nutrient analysis is consistent with patterns of sequestering and deficiency. We also expect to find high rates of malnutrition in conjunction with significant malaria infection. Ultimately, this project strengthens understandings of connections between agricultural policy, climate change, micronutrient malnutrition, and infectious disease.

Abstract Name: Student Athletes' and Coaches' Perception of Nutrition Education

Nutrition education is essential for student athletes to prevent, identify, and treat any potential disordered eating behaviors they present. Previous research on this topic has been limited and constrained. A study conducted by Hines and colleagues (2019) in Wisconsin found that athletes in both types of sports, lean and non-lean, had comparable nutrition education and that athletes in those sports felt more pressure about weight gain as well as greater concern about eating disorders. They also found that nutrition education was particularly lacking among female athletes (Hines et al., 2019) while a more recent study found that a nutrition education intervention had an impact on female athletes' dietary habits, though they concluded that there must be further research done on educational strategies for female athletes with less limitations (Veloso-Pulgar & Farran-Codina, 2025). Additionally, a study from Lebanon on professional athletes' and coaches' perceptions of nutritional knowledge found that the nutritional knowledge of coaches was much larger than the nutritional knowledge of the athletes (Boumosleh et al., 2021). My research question asks how student perceptions on nutrition education differs across gender or types of sports, and I aim to locate any opportunities for the improvement of nutrition education in athletes. Moreover, I will also be comparing athletics staffs' perceptions of nutrition education with athletes' perceptions of nutrition education. Participants include student athletes and athletics staff from Florida Gulf Coast University and the University of Wisconsin- Eau Claire.

Abstract Name: Investigating the Role of Locally-Derived Complement Factor B in Intestinal Barrier Protection

Inflammatory Bowel Disease (IBD) is a disorder marked by chronic inflammation and barrier dysfunction of the intestine. There are more than three million people with IBD in the US alone, and ten million globally. Not much is known about how chronic intestinal inflammation is triggered and there are very few effective treatment options for patients. The complement system is a part of the immune system and Factor B is an important component of the alternative pathway within the complement system. Although there have been elevated levels of complement Factor B observed in human IBD patients, its role in intestinal protection is unknown. If there was an understanding of how it influences disease progression and contributes to the maintenance of the epithelial barrier, then potential specific drug targets for IBD and other related diseases may be discovered. We hypothesize that Factor B plays an important role in the gut and is crucial for preventing intestinal inflammation during disease. To study the importance of Factor B during IBD, we used an animal model of DSS to induce colitis-like disease. We used a whole-body knockout model as well as tissue specific deletion of Factor B which are VillinERT2Cre (epithelial produced) and AlbuminCre (liver produced). Tissue was collected from the gut to validate both the localization of Factor B and epithelial integrity through immunohistochemistry. ELISAs were performed on serum and tissue lysates to quantify inflammatory cytokines. Additionally, we will use quantitative PCR to observe gene expression of Factor B. Additionally, immunohistochemistry confirmed the loss of Factor B expression in intestinal epithelial cells of VillERTCre⁺ mice. ELISA data suggests increased inflammatory markers in DSS treated knockout mice. Our findings suggest that locally-driven Factor B has a protective effect on intestinal barrier integrity and in the regulation of inflammation during colitis.

Abstract Name: Neurodivergent Adults Outperform On Complex Question Production Under Cognitive Load

When English-speaking children ask questions with embedded clauses (e.g., Who do you think the cat chased?), they sometimes produce an extra “medial” question word (e.g., What do you think who the cat chased?). Prior work suggests these errors may reflect immature linguistic competence or limitations in developing cognitive mechanisms. If these errors are the result of children having a lower threshold for cognitive load, it should be possible to induce similar productions by overloading adults’ cognitive mechanisms. This study explores whether neurodivergent adults differ from neurotypical adults in producing complex questions under such conditions. Methods: Twenty-nine college students were randomly assigned to one control and two experimental conditions. After exclusions, 25 participants remained, and seven self-identified as neurodivergent. In experimental conditions, participants memorized three sentences before reading each scenario and were asked to recall them after posing their question; the control condition involved no cognitive load. Trials were presented in random order via FindingFive, and responses were transcribed and verified. Results: Grammatical, multiclausal questions constituted 52% of productions. A variety of production types were used which are syntactically simpler than multiclausal questions, including monoclausal (34%), “about” questions (11%), and yes/no questions (3%). Bayesian ANOVAs revealed no significant effect of neurodivergence overall, though neurodivergent participants were slightly less likely to

use monoclausal questions (BF10 = 1.136) and, on average, produced more grammatical multiclausal questions than neurotypical peers. We attribute the lack of significance to small sample size. Discussion: Preliminary findings suggest neurodivergent individuals may outperform neurotypical peers on complex question production under cognitive load, relying less on workarounds. Regardless of the exact explanation, this study has implications for linguists and psychologists alike as it suggests a difference in performance between neurotypical and neurodivergent individuals on this type of task.

Abstract Name: Produced Water Reuse

Produced water, a byproduct of oil and gas production, is often treated as waste despite its high ionic and mineral content. This study investigates the potential reuse of produced water as an electroactive medium capable of storing or conducting electrical energy. By combining produced water with clay-rich soils to create conductive mud formulations, experiments were conducted to analyze voltage retention and current flow when subjected to small potential differences. Various mixtures were tested to evaluate how factors such as salinity, clay content, and water volume influence conductivity and energy storage. Preliminary findings suggest that clay-based muds with higher salinity concentrations demonstrate greater voltage output compared to sandy counterparts, likely due to increased ionic mobility and tighter molecular packing within the clay matrix. These results highlight the feasibility of converting waste fluids from petroleum operations into energy-supporting materials, contributing to sustainable resource utilization and circular energy recovery within the oilfield ecosystem.

Abstract Name: Using Spearman's Rank Correlation Analysis method to determine the relationships between Produced Water quality parameters and their suitability for water membrane distillation

Access to reliable water sources is critical for sustainable desalination processes such as membrane distillation (MD). This study evaluated the physicochemical properties of twenty water samples to assess their suitability for MD applications. Five key water parameters were analyzed: pH, conductivity, free ammonia, total alkalinity, and sulfate concentration. Suitability thresholds were defined based on known operational risks, including corrosion at low pH and scaling at elevated sulfate or conductivity levels. Results showed that most samples (15 of 20) exhibited favorable characteristics for MD, with near-neutral pH and moderate alkalinity supporting process stability. Samples with very high conductivity and sulfate concentrations (e.g., >135,000 $\mu\text{S}/\text{cm}$ and >90 mg/L) were classified as “moderately suitable” due to scaling risk. Two samples with extremely low pH (~3.7) were deemed unsuitable for MD because of corrosion risk and reduced

efficiency. Spearman correlation analysis highlighted key relationships, such as the positive association between alkalinity and pH stability and the contribution of sulfate to scaling risk. These findings emphasize the value of targeted water quality assessment in desalination system planning. By linking physicochemical parameters to performance suitability, this research supports informed decision-making for MD deployment and offers insight into managing water sources in regions facing contamination and scarcity challenges.

Abstract Name: Detecting Ranavirus using TaqMan Quantitative PCR in Aquatic Turtles from Central and Southeastern Ohio

Ranavirus is a global pathogen that has caused mass mortality events in wildlife species including amphibians, reptiles, and fish. Frog virus 3 (FV3) ranavirus is the most prevalent lineage and has been found to infect Midland Painted (*Chrysemys picta marginata*) and Eastern Box (*Terrapene carolina carolina*) turtles in Ohio. Even with the increase in reporting of ranavirus in amphibians, the data for turtle populations are limited. This study aims to assess the presence of ranavirus found in aquatic turtle populations at Capital University's Primmer Outdoor Learning Center (Logan, Ohio), Glacier Ridge Metro Park (Plain City, Ohio), and Blacklick Woods Metro Park (Reynoldsburg, Ohio) in Central and Southeastern Ohio. Turtles were captured and adhered to standardized trapping methods with ten Promar collapsible live bait traps per session where oral swabs and non-invasive tail clipping samples were collected. Four trapping sessions have been completed with twenty-nine total samples collected to date. In the lab, DNA extraction was performed using the Qiagen DNeasy Blood & Tissue Kit followed by quantitative polymerase chain reaction (qPCR) with a TaqMan assay and internal positive controls to detect the presence of ranavirus. Preliminary screening with qPCR (n=9) detected positive samples from one Eastern Musk (*Sternotherus odoratus*) turtle with a wound from Primmer Outdoor Learning Center, one adult Midland Painted (*C. picta*) turtle from Blacklick Woods Metro Park, and one juvenile Midland Painted (*C. picta*) turtle from Glacier Ridge Metro Park. Additional swab and tissue samples will be collected and analyzed along with filtered water environmental DNA (eDNA) to evaluate the significance of these results. This project will provide a better understanding of ranavirus prevalence in aquatic turtle populations in Ohio.

Abstract Name: Transforming Underused Office Space into Mixed-Use Housing and Providing Community Amenities

Denver faces a series of overlapping challenges: a shortage of affordable housing, rising living costs, and a growing number of underused office buildings resulting from post-pandemic shifts in workplace patterns. These circumstances call for design approaches that reconsider how existing buildings can be adapted and reactivated. This project researched adaptive reuse as a viable response by transforming an existing office building into a mixed-use residential community centered on affordability, wellness, and social connection. The proposal positions the building as a neighborhood asset by integrating programs that support physical,

mental, and social well-being. The design strategy draws on biophilic design, environmental psychology, and the WELL Building Standard, which guided decisions related to spatial organization, material selection, and amenity placement. The lower-level amenities, including a community café, nutrition center, library, coworking rooms, youth spaces, and outdoor terraces, are arranged to support daily activities and encourage interaction among people of different ages. The residential floors have a repeatable unit layout that improves efficiency and promotes whole-building performance. Across the project, the design emphasizes daylight, intuitive circulation, and comfortable, dignified living environments. A resident-focused survey supports the neighborhood analysis, helps identify which services were most needed, and how the building could contribute meaningfully to the surrounding environment. This research shaped the program and ensured the proposal responded to actual local needs rather than imposing predetermined amenities. Ultimately, the work positions adaptive reuse as a meaningful tool for addressing housing and community challenges in cities like Denver. By combining affordable housing, health-supportive environments, and community-oriented programming, the project demonstrates how an existing building can be reimaged to better serve both its residents and the broader neighborhood.

Abstract Name: Synthesis of Novel Melanoma-Inhibiting Compound A-11

Melanoma is the fifth most common cancer in the United States, with cutaneous melanoma accounting for 94% of cases. Cutaneous melanoma originates from melanocytes and is a highly aggressive malignancy. A patented compound, A-11, has demonstrated potential for inhibiting melanoma growth and the removal of existing melanoma cells. Studies have shown A-11 to inhibit melanoma growth in zebrafish embryos and in mouse melanoma cells by mitosis reduction causing morphological changes resembling reversion to normal melanocytes. Studies of this compound indicate that it could be a powerful new therapy for melanoma cancers, however, the current synthetic scheme for this compound has shown little reproducibility, with the remaining amount of the compound dwindling. The aim of this research is to develop and carry out a modernized synthetic scheme to reliably and efficiently produce larger quantities of A-11 for the purpose of further cancer treatment research and application. Thus far, a full scheme has been developed, and the first synthetic intermediates have been successfully produced and characterized in good yield.

Abstract Name: Testing Potential Antibiotic Adjuvant Compounds for STP1 Inhibition

Staphylococcus aureus (*S. aureus*) is a Gram-positive, opportunistic bacterium that can cause a variety of life-

threatening infections. *S. aureus* has acquired resistance to many different antibiotics, including vancomycin, methicillin, and penicillin. Previous work in our lab identified that brominated carbazoles can potentiate the activity of β -lactam antibiotics against methicillin-resistant *S. aureus* (MRSA). Small molecules, such as these carbazoles, that increase the efficacy of existing antibiotics against resistant infections are classified as adjuvants. Serine-threonine kinase (STK1) was hypothesized to be the target of these compounds; however, testing demonstrated that they did not alter the activity of its kinase domain. As a result, we began studying the cognate phosphatase of STK1, serine/threonine phosphatase (STP1), to determine whether this protein was the target of these compounds. STP1 is an enzyme in *S. aureus* that plays a role in cell processes, such as cell wall synthesis and homeostasis, cell division and size, and biofilm formation. It is also found to contribute to acquired antibiotic resistance. Inhibition of STP1 poses a promising mechanism for antibiotic adjuvants. To study STP1 function, we expressed STP1 in Origami B(DE3) cells and purified the recombinant protein using affinity chromatography. We utilized a phosphatase assay to screen the impact of the carbazoles on STP1 catalysis. We demonstrate that many carbazoles are competitive inhibitors of STP1 and have begun to establish structure-activity relationships. The inhibition of STP1, therefore, can be linked to the adjuvant activity of these compounds.

Abstract Name: Synthesis of Novel Fluorinated and Deuterated Methylenedioxymethamphetamine (MDMA) Analogues

Recent studies have shown that 3,4-methylenedioxymethamphetamine (MDMA) can be effective as a treatment of post traumatic stress disorder, (PTSD)¹. The goal of this research is to synthesize next-generation analogues of MDMA that could be tested for PTSD treatment efficacy and offer alternative treatments with improved pharmacological profiles. Target analogues include partially fluorinated and deuterated versions of MDA, MDMA, and methylone. A series of reactions, purifications, and chemical analyses are being carried out to create these new analogues. F2-MDA and F2-MDMA have already been synthesized and characterized. F2-methylone and deuterated analogues are currently in preparation. Pharmacological assays for clinical efficacy will be performed by collaborators.

Abstract Name: Detecting Antibiotic Resistance Patterns in Aquatic Turtles from Central and Southeastern Ohio

Antibiotic resistance is an emerging concern for public and environmental health, affecting humans, wildlife, and ecosystems. Aquatic turtles can act as reservoirs and vectors for antibiotic resistant bacteria, although information on resistance patterns in turtle populations is limited. This study aims to assess the presence of antibiotic resistant bacteria in aquatic turtle populations at Glacier Ridge Metro Park (Plain City, Ohio), Blacklick Woods Metro Park (Reynoldsburg, Ohio), and Capital University's Primmer Outdoor Learning

Center (Logan, Ohio) in Central and Southeastern Ohio. To date, seven trapping sessions have been completed with twenty-four total samples having been collected. Turtles were captured following standardized trapping protocols using ten Promar collapsible live bait traps per session. During retrieval, oral, plastron, and cloacal swabs were streaked on nutrient agar plates in the field and an additional oral swab was collected for further analysis. In the lab, the bacteria from the plates were processed using a Kirby-Bauer assay to evaluate antibiotic susceptibility. The additional oral swab was used for DNA extraction using the Qiagen DNeasy Blood and Tissue Kit, followed by PCR amplification, and visualized using gel electrophoresis. Preliminary screening with Kirby-Bauer and PCR detected antibiotic resistance in Eastern Musk (*Sternotherus odoratus*) turtles from Primmer Outdoor Learning Center and Midland Painted (*Chrysemys picta marginata*) turtles from Glacier Ridge Metro Park and Blacklick Woods Metro Park. Additional swabs will be collected and analyzed along with filtered sediment environmental DNA (eDNA) to evaluate the significance of these results. This research will provide a better understanding of antibiotic resistance in aquatic turtle populations in Ohio.

Abstract Name: Journals as Labs: How Student Reflections and Case Autopsies Decoded AI-Generated Realities

In an era increasingly shaped by artificial intelligence, cultivating AI literacy among students is essential for responsible digital citizenship. This mixed-methods study, conducted through Georgia State University Perimeter College's Center for Outreach, Research & Engagement, explores how undergraduate students interpret and critically engage with AI-generated content using reflective journals and case autopsies. Drawing from a semester-long inquiry, students analyzed fabricated news headlines and narratives produced by AI, documenting their reactions and reasoning in personal journals and collaborative case studies. The research revealed that 83.3% of participants demonstrated discernible AI literacy, successfully identifying synthetic content and articulating nuanced critiques of its implications. Qualitative analysis of student reflections uncovered recurring themes of skepticism, ethical concern, and media awareness, suggesting that reflective practices foster deeper understanding of algorithmic influence. This project positions student writing as a laboratory for decoding digital realities, offering a replicable model for integrating AI literacy into humanities curricula. By bridging critical thinking with emerging technologies, the study contributes to pedagogical strategies that empower students to navigate—and challenge—the complexities of AI-mediated information.

Abstract Name: Identifying Hyper- and Hypo-Connectivity in Autism Spectrum Disorder Through Default Mode Network Analysis Using Resting-State fMRI

This project examines differences in how strongly key brain regions communicate with one another, a pattern often referred to as functional connectivity, in individuals with Autism Spectrum Disorder (ASD), with a

focus on the Default Mode Network (DMN). This network becomes active during self-reflection, social understanding, and the interpretation of thoughts and feelings. Because many traits associated with ASD relate to these processes, studying this network may offer insight into underlying neural patterns. The data used in this study come from the Autism Brain Imaging Data Exchange (ABIDE), which provides resting-state fMRI scans from many research sites. After applying quality controls, the dataset included 871 participants, 403 with ASD and 468 in the control group. To study the DMN, a widely used brain atlas was utilized to identify three core regions, which were represented by 16 smaller parcels using the Schaefer atlas applied to the ABIDE data. Each pair of parcels was then examined to measure how strongly these regions communicated during rest. When comparing the ASD and control groups, a clear pattern emerged: individuals with ASD showed reduced communication between two major DMN hubs, the medial prefrontal cortex and the posterior cingulate cortex. These areas play central roles in social reasoning and self-focused thought, and reduced communication between them has been proposed as a possible explanation for some core features of ASD. This project is ongoing, and the next stage involves using machine-learning methods to test whether these brain-based patterns can help classify ASD more objectively. By identifying consistent differences in how the DMN functions, this work contributes to the broader goal of developing reliable biological markers that could support, rather than replace, traditional behavioral assessments.

Abstract Name: Beyond ACEs: Considering the Role of Strengths-Based Developmental Assets in Reducing Justice Involvement among Black Youth

Black adolescents are overrepresented in juvenile justice systems, despite having similar offending rates compared to their white peers (Padgaonkar et al., 2021; Rovner, 2024), making it important to understand predictors of justice involvement. Adverse childhood experiences (ACEs) have been studied as a predictor, and have been linked with an increased risk of justice involvement and delinquency (Graf et al., 2021). ACEs negatively affect brain development by impairing the areas that are responsible in navigating through high stress situations or difficulties, which creates a vulnerability to justice system contact (Buimer et al., 2022; Kong et al., 2021). Building on this work, it is also important to move beyond ACEs and understand strengths that are related to less justice involvement. Thus, the current study tested whether ACEs and developmental assets predicted justice involvement. Participants were 237 Black adolescents 12 to 17 years of age ($M = 14.46$, $SD = 1.64$). The overall model was significant, $F(3, 221) = 5.114.24$, $p = .02$, $R^2 = .19$. Specifically, Black youths' adverse childhood experiences were not associated with juvenile justice involvement ($\beta = .02$, $p = .38$). However, developmental assets were significantly associated with less juvenile justice involvement ($\beta = -.01$, $p = .01$). Together these findings highlight the protective role of developmental assets in shaping justice involvement among Black adolescents. Interestingly, previous work has tended to focus on ACEs, but our findings highlight that when strengths are considered, they are a more powerful predictor of decreased justice involvement. The results suggest that promoting developmental assets may be a promising strategy for supporting healthy developmental pathways among Black youth.

Abstract Name: Geospatial Variation in Particulate Matter, Chronic Obstructive Pulmonary Disease and Life Expectancy in Texas

Particulate matter (PM) is an environmental pollutant with significant public health risks. However, the spatial relationship between PM levels, chronic obstructive pulmonary disease (COPD) and life expectancy across counties in Texas has not been fully explored. This study aims to examine the spatial distribution of PM in relation to COPD prevalence and life expectancy, with a focus on identifying geographic patterns and associations across Texas counties. County-level data on life expectancy, COPD prevalence and PM concentrations were obtained from County Health Rankings database. Data for COPD prevalence among U.S. adults were sourced from the Centers for Disease Control and Prevention database. Spatial analysis techniques including bivariate choropleth mapping and local indicators of spatial association (LISA) analysis were used to identify patterns of spatial clustering in Texas. Two-sided p-values were used for significance testing. All data were analyzed in R version 4.3.1. The analysis revealed significant spatial clustering in East Texas with higher concentrations of PM and elevated COPD prevalence compared to other areas in Texas. Additionally, clusters of lower life expectancy and higher PM levels were also evident in East Texas. In contrast, metropolitan areas despite having higher PM levels, showed higher life expectancy, likely due to better access to healthcare resources. The results highlight that air quality is a crucial determinant of health, with East Texas exhibiting high PM concentrations associated with increased COPD prevalence and lower life expectancy. In contrast, metropolitan areas, despite having elevated PM, show higher life expectancy likely due to better access to health resources. These findings highlight the need for maintaining air quality regulations, and emphasis on the importance of targeted public health interventions in rural areas. Addressing these disparities is essential to reduce exposure to PM and lower the prevalence of chronic respiratory diseases.

Abstract Name: Breaking the Mold: An Exploratory Analysis of Real-World AI Prompt Jailbreaking Scenarios and Their Implications for Cybersecurity

This paper presents a comprehensive analysis of real-world scenarios involving artificial intelligence (AI) prompt jailbreaking, where malicious actors exploit vulnerabilities in AI language models to elicit unintended or unauthorized responses. Through a thorough examination of existing literature and case studies of real-world scenarios, this paper identifies some common patterns, techniques and motivations behind AI prompt jailbreaking attempts and explores the potential consequences of such exploits, including dissemination of misinformation, manipulation of public opinion, and the compromise of sensitive information. An evaluation of 3 large language models (LLMs) are evaluated in total-GPT-3.5, GPT-4, and PaLM 2-against 6 different types of jailbreaking and malicious query types (persona-based, task exploitation, hypothetical

scenario, data exfiltration, and system prompt leakage). This study analyzes the jailbreaking and malicious query types described in this study to assess their robustness against such attacks. The findings in the paper indicate that the majority of such attempts seem to exceed 50% across all tested models, with persona-based jailbreaking attempts being demonstrated to have the highest effectiveness and yield rates out of all jailbreaking types. By investigating the intersection between the safety of AI language models, natural language processing, and cybersecurity, this paper aims to provide insights into the current state of AI prompt jailbreaking, the types of jailbreaking and inform the development into more effective countermeasures against such threats in order to mitigate the risks associated with jailbreaking, as these results underscore the critical importance for the need of urgent countermeasures to mitigate the risks posed by unethical AI jailbreaking.

Abstract Name: Domain-Specialized Genomic Language Models for Plastic-Degradation Detection

Plastic pollution is a rapidly escalating environmental crisis, and microbe-driven mitigation strategies depend on efficiently identifying the organisms and genes that support plastic breakdown. This project focuses on plastic-degrading bacteria and investigates how genomic language models encode and distinguish sequence features associated with plastic-degradation potential in both assembled genomes and unassembled sequencing reads. Large transformer-based genomic architectures trained directly on raw DNA have recently shown that they can capture biologically meaningful sequence regularities and support tasks such as species classification, gene annotation, and functional prediction without explicit feature engineering. Building on this emerging paradigm, we ask whether a domain-specialized genomic language model trained specifically on plastic-degrading bacteria can more sensitively and specifically detect plastic-degradation potential than a general-purpose model, and whether such a model can help reveal novel genes and pathways involved in plastic metabolism. In preliminary analyses, DNABERT-S, a species-aware genomic language model trained on a massive set of diverse bacterial genomes, achieves strong species-level discrimination on newly sequenced candidate plastic-degrading bacteria, suggesting that its embeddings can be used to map plastic-degradation potential across both assembled genomes and environmental metagenomic reads. To address this question systematically, we curate a benchmark dataset from PlasticDB and related resources that link genomes and enzyme sequences annotated for plastic-degrading activity with carefully matched non-degrading controls. Using this corpus, we train a domain-specialized genomic language model and adapt it for sequence-level annotation tasks, including predicting plastic-degrading potential in newly sequenced bacteria and environmental reads. We then compare its performance with DNABERT-S, focusing on classification accuracy and recovery of plastic-degradation genes and pathways. The goal is a plastic-focused genomic language model that enhances detection of plastic-degrading taxa and genes and prioritizes candidate enzymes and pathways for experimental follow-up in microbial bioremediation.

Abstract Name: Lignin Content in Salt-Exposed Loblolly Pines (*Pinus taeda*) as an Explanation of Reduced Wood Density Using the Acetyl Bromide Method

Coastal forests in the southeastern and mid-Atlantic regions of the United States experience salinization and hydrologic alterations leading to inland marsh migration and expanding ghost forests. Despite widespread tree mortality due to salinity intrusion, the processes driving tree decline and death in these systems are not fully realized. Recent studies have indicated that salt exposure is associated with reduced wood density in loblolly pine (*P. taeda*), but the cause of this altered wood property has not yet been identified. In this study, we hypothesize that reduced lignin content, where lignin is a compound that provides protection and rigidity, could be the source of wood density differences. To test this hypothesis, we compared lignin content from trees in the high-elevation forest (>1m, representing minimal salt exposure and low-elevation forest (<0.7m, representing high salt exposure) at three locations on the Delmarva Peninsula. We hypothesized that salt-exposed trees at Milford Neck, Delaware (nh=10, nl=8), Monie Bay, Maryland (nh=9, nl=10), and Brownsville Forest, Virginia (nh=10, nl=8) would have lower lignin content than their less-exposed upland counterparts due to reduced photosynthetic rates associated with salt stress, explaining the lower wood density found in these trees. Tissue samples were collected by coring trees with an increment borer, and a modified acetyl bromide method was utilized to determine wood lignin content. Samples were restricted to trees with known wood density and cell morphology (i.e., cell wall thickness and lumen area). Results from Monie Bay suggest lower lignin content in salt-exposed forest (mean = 20.86%) when compared to trees with lower salt exposure (30.70%, p-value=0.0001143898). Results from the Delaware and Virginia locations are pending.

Abstract Name: EV Range Estimation using Fuzzy Logic Model

This project developed a dynamic electric vehicle (EV) range estimation model using a fuzzy logic system which provides more accurate predictions than the predictions from the manufacturer's computers onboard the electric vehicle. Using the On-Board Diagnostics (OBD) data from a 2012 Chevrolet Volt, the model integrates real-world variables which significantly impacts the battery performance. Some key real-world variables include the driver's behavior which is quantified through "aggressiveness" (rate of acceleration) and "cruise steadiness" (speed variance), and different environmental conditions like the ambient temperature. The fuzzy logic system processes these different inputs and the battery's State of Charge (SoC) in order to generate a dynamic multiplier which ranges from 0.6 to 1.1. This multiplier adjusts the baseline range, accounting for up to a 40% range reduction in adverse conditions or a 10% gain in optimal scenarios. Membership functions for temperature and driving behavior were refined based on already established research from sources like AAA and the Department of Energy, which confirms range loss at extreme high and low temperatures. The challenges which were encountered included limited vehicle access, a small dataset, and the use of an older hybrid car which has a degraded battery that could not be fully charged. Despite these limitations, the model was successful in demonstrating a physics-aligned approach to EV range prediction, proving that the fuzzy logic framework can effectively translate complex, real-world variables into a quantified way in which a more accurate range estimate is possible.

Abstract Name: The Immigrant Plight

The immigrant plight is a complex journey, often unknowingly shaped by colonial legacies and racial hierarchies. For decades, immigrants have entered the U.S. under the false premise of the 'American Dream', only to face economic hardships, racism, social isolation, and loss of identity. For brown men in particular, this experience is further complicated by pervasive stereotypes that label them as 'terrorists'. This paper explores the immigrant experience of two brown men in two contemporary South Asian Literature. In both cases, their legal status conveys a crucial role in determining their access to Western economic and social benefits. When human rights are denied, undocumented immigrants are forced to endure hardships in secrecy, isolating themselves to avoid deportation. The experiences of these men are not at all unique. Rather, they reflect the broader stories of migrants who sacrificed their homes for socio-economic betterment. However, their realities post-9/11, gives us a unique perspective into the male, brown migrant experience in modern U.S. particularly how brown bodies are radicalized and profiled despite their deperate origins from the convicted terrorist. These men experience a collective alienation, which raises doubts about whether assimilation is truly accessible. The stark difference in their economic background challenges the concept of 'correct migration', if it's the significant factor to white-acceptance. Yet their decision to abandon their American dream pursuit challenges if the sacrifice it demands is justified. With the current political climate surrounding immigration, it's important to continue the analyzation of the migrant experience. Their story, while fictional, is common amongst migrants across generations. It challenges whether assimilation is attainable or is it rooted in deeper, systematic forces beyond the immigration process itself. It's important to continue this dialogue to raise understanding of their invisible struggles, and larger structure that shape them.

Abstract Name: The Language of Stories: Effects of Consolidation on the Content and Verbal Communication of Memories

New memories are fragile and must undergo a process known as memory consolidation to prevent forgetting. Mechanisms of consolidation facilitate the selective retention of salient information and the transformation of the content of memory traces. However, prior work has generally utilized static images as stimuli, limiting our understanding of how consolidation influences the structure of memories for the dynamic and multidimensional experiences we encounter in everyday life. To address this gap, the current work examines free recall of a naturalistic movie stimulus. Participants are asked to recall a short animated movie both immediately after watching and after a week's delay. As a control for repeated recall, a second group of participants only engaged in the delayed recall test. Leveraging this design, we will explore how the content of memories for a naturalistic stimulus changes over time through differences in verbal communication during the free recall sessions. We will utilize a combination of manual coding schemes and natural language

processing algorithms to analyze each subject's transcripts. Analyses will focus on studying differences in the number of total words, parts of speech (nouns, verbs, etc.), the proportion of highly emotional words used, as well as other queries of the specific content recall used during the two recall sessions. We hypothesize that, with consolidation, participants will demonstrate more linguistically rich speech (e.g., reduced number of total pauses and/or filler words compared to other parts of speech) and will incorporate greater emotional words, consistent with consolidation's prioritization of salient or important information. Together, these results will help adjudicate the precise changes in the content and communication of episodic memories due to consolidation.

Abstract Name: Designing an Assistive Eye-Dropper Device for Individuals with Limited Hand Dexterity

Many medical conditions affect an individual's mobility, including arthritis and Parkinson's disease. In the United States, these diseases are extremely prevalent, making it difficult for individuals to perform everyday tasks. Individuals required to use eye drops struggle especially, as motor impairments make it challenging to squeeze eye-dropper bottles. This prevents them from receiving the proper dosage amount to their eyes. Attempted solutions on the market are uncomfortable, ineffective, and not standardized in the U.S., indicating a gap in current assistive devices. Our team is designing a novel eye-drop assistive device to simplify this task effectively. Our design utilizes a button-dispenser mechanism. Whereas eye-dropper bottles typically require squeezing, having a single push-button to dispense the liquid requires much less force and precision from the user. Employing the same system as keycaps on a keyboard, our push button is part of an external frame that will fit around a standard eye-dropper bottle. Pressing the button will cause force to be applied onto the bottle, squeezing drops out in a top-down manner. The push button and frame will be 3D printed using common plastic filaments such as PLA and PETG. Our design process begins with modeling our assistive device in Autodesk Fusion. After printing out prototypes to test with an eye-dropper bottle, we will apply various mechanical tests to ensure a high level of quality is met for our stakeholders involved in the distribution and usage of the device. The completed device will allow users to easily self-administer eye drops at home, reducing the force needed to squeeze the bottle and providing consistent dosage delivery. Results and applications will be discussed in the context of improving medication independence for individuals with limited dexterity. Additionally, our design will advocate for greater accessibility in medical care through low-cost engineering solutions in everyday routines.

Abstract Name: Investigating Changes in Cellular Focal Adhesions during Hierarchical Collagen Fiber Formation to Better Drive Tendon and Ligament Regeneration

Collagen fibers are the primary source of strength and function in connective tissues, particularly tendons and ligaments. Cells organize these fibers hierarchically, assembling them from nm-wide fibrils into larger fibers and fascicles, growing with mechanical demand. These fibers don't regenerate after injury or with repair, limiting treatment options. There's a need to better understand how cells form hierarchical fibers to engineer functional repairs and replacements. It's well established that cells form aligned fibrils largely through cell contraction forces, highly regulated via cellular focal adhesions (FA) with the extracellular matrix. However, this work has primarily been done on 2D surfaces and in unorganized gels, thus the mechanisms that regulate fiber and fascicle formation are largely unknown. Previously, we developed a culture system that guides anterior cruciate ligament (ACL) fibroblasts in high-density collagen gels to produce aligned collagen fibrils by 2 weeks, which mature into native-sized fibers and fascicles by 4 and 6 weeks. The objective of this study was to explore how FAs change in size and number during hierarchical fiber formation to gain a better understanding of how cells regulate hierarchical fiber formation. To do this, ACL fibroblasts were seeded into high-density collagen gels and cultured in our device for up to 6 weeks to guide hierarchical fiber formation. Similar to previous studies, we found cells formed aligned fibrils by 2 weeks, and larger fibers and fascicles by 6 weeks, coinciding with increased tensile strength and protein accumulation. To evaluate FA formation, vinculin and actin were fluorescently stained at each timepoint. We found that FAs appear to become larger and more diffuse as aligned fibers form in static culture, suggesting a shift in cellular mechanotransduction. Ongoing work is evaluating how dynamic cyclic load alters FAs to further evaluate how cells sense mechanical cues in developing hierarchical fibers.

Abstract Name: Physical Properties of Cellular Environments Impact Intercellular Adhesion via Heterochromatin Machinery

Cells can sense and respond to their physical environment in a process known as mechanosensing. These mechanical signals can affect the nuclear envelope and how heterochromatin is organized. However, the role of substrate stiffness in gene silencing with heterochromatin is still unclear; better understanding it could reveal how mechanical environments shape cell behavior in development and disease. Fission yeast is one of the most well-studied organisms for heterochromatin assembly and can grow in liquid and solid media. We prepared various solid media with different substrate stiffnesses, and by performing bioindentation, we quantified stiffness with measurements of nN and nm precision, ranging from 1kPa to 100kPa. We then grew fission yeast cells on those media and measured how colony stiffness changes as a function of the substrate stiffness. Our results suggest that cells can increase their stiffness on hard substrates, suggesting that cell-to-cell adhesion is dependent on the extracellular biophysical cues. We also show that this adaptation to stiffness partially depends on heterochromatin machinery like Clr4 and Ago1. These findings suggest that the heterochromatin machinery is required to facilitate the nuclear mechanical response to physical environments. These findings may have applications in stem cell engineering; the physical properties of the cellular environment could be used to differentiate stem cells in conjunction with chemical and biological cues.

Abstract Name: Los Nazis en México: The Untold Relationship Between Mexico and Anti-Nazism

This research project seeks to bring light to the largely overlooked history in Mexico and explores anti-fascism and anti-Nazi propaganda posters created by Mexican artists, situating these works within broader traditions of political art, propaganda studies, and transnational resistance movements. This project will expand on the current literature that rarely addresses Mexico's explicit cultural opposition to fascism or the global circulation of its anti-Nazi imagery. By analyzing propaganda posters created by Mexican artists, including political cartoonists, state-sponsored illustrations, and members of anti-fascist cultural leagues, this study brings new attention to Mexico's role as one of the most outspokenly anti-Nazi countries in Latin America. This project combines archival research, visual analysis, and historical context to assess how Mexican artists used design, symbolism, and rhetoric to denounce totalitarianism. Additionally, this research touches on the unity between the United States and Mexico through a joint effort in aerial combat against a global threat. It further explores underlying social, cultural, and moral issues expressed through these posters, such as anxieties about authoritarianism, refugee solidarity, and the belief that art served as a moral tool in global political struggles. The major impact of this project lies in recovering and interpreting a visual archive that demonstrates Mexico's cultural agency on the world stage during World War II. The findings reveal how Mexican artists shaped public opinion, fostered anti-fascist identity, and contributed to hemispheric efforts against Nazism, which challenged assumptions that Latin American involvement was passive or nonexistent. Target audiences include scholars of Latin American history, art history, political communication, diplomacy, and students interested in global anti-fascist movements. By emphasizing Mexico's creative resistance to Nazism, this research enhances understanding of the interconnectedness of art, politics, and ideology, enriching the field with a more inclusive and transnational narrative of anti-fascist cultural production. Keywords: Mexico, anti-fascism, Nazis, propaganda posters

Abstract Name: The Role of WNT Signaling in ALS

Amyotrophic lateral sclerosis (ALS) is a severe and incurable neurodegenerative disease characterized by the loss of motor neuron function and physical impairment. The molecular mechanisms underlying this devastating disease are poorly understood, so further study is necessary to develop therapeutic interventions. In previous studies, links have been discovered between ALS and mutations in RNA binding proteins such as FUS. Our lab recently used spatially resolved RNA sequencing to track gene activity in ALS patient derived motor neurons with a mutation in the FUS protein. Our preliminary data found an upregulation in WNT protein signaling. While the WNT protein family has a known role in development and neuronal function, its relationship with ALS remains undefined. This project aims to examine how WNT signaling is altered in ALS to further characterize the pathways this disease impacts. To investigate the role of WNT signaling in ALS, seven *C. elegans* strains carrying fluorescently tagged WNT components, developed by the Pani Lab, were crossed with a double mutant strain derived from two *C. elegans* ALS model strains, *fust-1* (csb21) and *tdp-1* (csb28). Spinning disk confocal microscopy was then used to characterize protein localization in both normal and mutated individuals across multiple life stages, from larvae to gravid adults.

We first imaged unique localization patterns in each WNT strain without any ALS mutation present. We identified characteristic patterns that define predictable protein dynamics in each strain throughout each life stage. Next, we initiated crosses between the WNT strains and the line with the *fust-1/tdp-1* mutations. However, obtaining these double mutants has proved challenging and is still ongoing. Once these crosses are complete, we will perform imaging and compare the patterns against the WNT localization previously identified in wild types. This will be crucial to recognizing what WNT pathways are altered and at what life stages.

Abstract Name: Genetic Continuity Analyses of Northern East Asians

Many different populations live in present-day Siberia and Northern East Asia, reflecting a diversity of ancestries. While ancient DNA has been extensively sampled across this region, a test of direct ancestry has yet to be done to establish the relationships between modern populations and these ancient populations. Using a previously developed test of direct ancestry, or genetic continuity, we analyzed whether modern reference populations from the 1000 Genomes Project and ancient groups from this region were genetically continuous with each other. We found a few examples where continuity tested true in the Shandong region, but most ancient groups were not directly ancestral to any analyzed present-day population. We observed closer relationships between some younger ancient groups and modern populations; for example in the Amur River Basin. Despite the lack of clear examples of direct ancestry, our tests provide valuable insight into the genetic relationships between ancient and present-day populations in Northern East Asia, providing us a better understanding of the evolutionary history of humans in this region.

Abstract Name: Structural Expansion of Fleximer Nucleosides via Alkyne Spacer for Enhanced Antiviral Activity

Nucleoside analogues are commonly used for the treatment of various viral diseases and cancers by targeting key biological pathways involved in DNA replication, subsequently inhibiting viral replication. The Seley-Radtke group developed a novel class of flexible nucleoside analogues, termed “fleximers,” that split the purine ring system via a single carbon-carbon bond. This modification allows for the free rotation of the nucleobase which may overcome point mutation. Fleximers have demonstrated broad-spectrum antiviral activity against several viral families such as Ebola, Dengue, and SARS-CoV-2. This project aims to enhance the fleximer technology by replacing the single carbon-carbon bond with varying groups such as alkyne and

alkene. This modification changes the bond distance and spatial geometry of the analogue which may enhance the analogue's ability to access and interact with viral binding pockets more efficiently. The synthesis of each alkyne-expanded nucleoside consisted of the construction of the sugar, the installation of the alkyne group onto the pyrimidine base, the coupling of the alkyne-functionalized pyrimidine to the sugar moiety via a Sonogashira reaction, and finally an instillation of a McGuigan protide prodrug for efficient intercellular transport. To ensure structural accuracy, the compounds were characterized using ¹H NMR and ¹³C NMR. After successfully synthesizing the alkyne-expanded analogues, a series of antiviral assays were conducted to evaluate the biological activity of these compounds against a panel of viruses. In preliminary studies, alkyne-expanded fleximer nucleosides have displayed moderate anti-viral activity against Ebola, Chikungunya, and SARS-CoV-2. These promising results suggest that fleximer nucleosides can potentially contribute to the development of novel compounds for potential antiviral drugs and therapeutics by investigating the effects of various structure-activity based modifications.

Abstract Name: Relating Ultra-Fine-Scale Structural Metrics to Cryptobenthic Reef Fish Body Size and Community Structure in Florida

The Florida Reef Tract is one of the world's largest barrier reefs and North America's only living one, making it a hotspot of productivity and crucial to reef fish communities in the Caribbean. Cryptobenthic fishes (< 5cm) typically remain close to structure in coral reefs within reef refuges, which make them difficult to identify and study. Their size and cryptic behavior has created a knowledge gap in scientific literature that we aim to close with a combination of cryptobenthic community data and structural data from shallow coral reefs. The common fish anesthetic, clove oil, was used to collect cryptobenthic species inhabiting Florida Wildlife Commission Coral Reef Evaluation and Monitoring Program sites (FWC CREMP) in an area of 1m². After collecting cryptobenthic fishes, researchers performed underwater photogrammetry on the reef sites to produce high-resolution 3D models with Agisoft Metashape. Utilizing technology such as photogrammetry allows for holistic, noninvasive, accurate recreation of reefs to analyze benthic and coral species present. Additionally, it creates the ability to extract complexity and relief metrics on a fine-scale to determine the link between structure and diversity. Complexity values for each reef patch model will be partitioned into multiple scales ranging from 1mm to 0.5m. Ultimately, this study examines the connection between fish size and physical structure present using trait data measured with ImageJ software in tandem with structural data from Metashape. The implications of these findings can be used to consider a broader perspective on evolution and how rugosity is associated with cryptobenthic body size limitations through an ecological lens. Our results will contribute to the continued understanding of cryptobenthic fish habitat use and will be distributed to the FWC to help inform local policy management and implement optimized artificial reefs in response to natural reef declination.

Abstract Name: Smooth Muscle Klf4 Promotes Spp1⁺ Macrophage Accumulation in Obese Adipose Tissue

Background: Obesity remodels adipose tissue macrophages (ATMs), but how they respond to signals from neighboring smooth muscle cells (SMCs) is less clear. Here we re-analyzed multiple single-cell RNA-seq experiments to build a unified view of adipose immune and stromal cells in a mouse model with SMC-specific Klf4 deletion. **Methods:** We combined 16 10x Genomics libraries from three experiments, including chow and diet-induced obesity (DIO) as well as wild-type (WT) and smooth-muscle Klf4 knockout (Klf4-SMC-KO) mice on DIO. After quality control, 27,398 cells remained. Datasets were integrated with SCTransform and canonical correlation analysis (Seurat v5), using experiment as a batch variable. We then subsetted 12,045 macrophage and mural cells based on marker gene expression and reclustered them using 12 principal components. We curated markers from the adipose macrophage literature (Itgax/CD11c, Cd9, Cd63, Lpl, Steap4, Mafb, Cybb, Pdgfra, Jam2, Prox1, Myocd) and used those to annotate clusters and assess diet- and genotype-dependent changes. **Results:** Single-cell RNA-seq of adipose SVF revealed 18 transcriptionally distinct clusters including macrophages and mural cells. Cluster 0, the largest cluster, contained an Spp1-high macrophage population previously linked to pro-inflammatory and pro-fibrotic functions, crown-like structures, and insulin resistance. In our dataset, Spp1⁺ macrophages increased from 4.2% of cells in chow to 15.9% in DIO (3.8-fold) and within DIO diet, this cluster was more abundant in Klf4 WT than Klf4-SMC-KO mice (0.152 vs 0.083; 1.8-fold higher in WT), suggesting that SMC Klf4 may promote accumulation of this potentially maladaptive macrophage population, which has also been implicated in vascular dysfunction. **Conclusion:** This integrated analysis, built collaboratively with undergraduate students, defines a macrophage- and mural-cell-focused atlas of adipose stromal vascular cells across sorting strategies, diets, and SMC-Klf4 genotypes, and provides a foundation for targeted differential expression and pathway analyses.

Abstract Name: Exotic Dancers and Employment Status: Independent Contractors or Employees Under the Fair Labor Standards Act (FLSA)

Abstract The employment classification of exotic dancers under the Fair Labor Standards Act (FLSA) remains capricious, with courts reaching divergent conclusions about whether dancers are employees entitled to wage protections or independent contractors outside the statute's scope. This project explores that divide by examining key federal and state cases and analyzing how judges apply the economic realities test, which considers control, financial risk, investment, skill, permanence, and the dancer's role within the business. While dancers may appear to have autonomy, many decisions highlight their economic dependence on clubs for income, customer access, and workplace structure. Methodologically, the research synthesizes judicial reasoning across jurisdictions, compares diverse applications of the economic realities test and engages with regulatory guidance and scholarly commentary to assess how effectively FLSA's six-prong economic realities test functions in industries with unconventional work arrangements. The review reveals that, despite surface level autonomy, many courts find dancers to be economically dependent on clubs for income, customer access, and workplace structure. However, a minority of courts treat dancers as independent contractors, usually when evidence shows substantial control over schedules, routines, permanence and profit-related decisions. These results highlight the difficulty of fitting nontraditional work arrangements into an employment framework designed for more conventional jobs as well as the inconsistencies in the application

of economic realities test. This study encourages debates about worker status in all the professions in the gig economy.

Abstract Name: "You Only Go to Title IX When Something Bad Happens:" Addressing the Gap in Knowledge about Healthy Relationship Skills and Programming among College Students

A national report from Harvard's Making Caring Common project found that 65% of 18 to 25-year-olds wished they had received more guidance on emotional aspects of romantic relationships in health or sex education classes. These same concerns are present on Siena University's campus as well, so our project used community engagement best practices to examine how student-driven prevention education and digital outreach can enhance student knowledge and skills in relationship management. From the Spring 2025 through the Fall 2025 semesters, a team of students in the Nonprofit Excellence and Transformation (NExT) Fellowship collaborated with the Title IX, Health Promotions, and Student Life offices to expand educational efforts beyond formal presentations to answer the question: how can we foster healthy relationships and boundaries on a university campus? We examined strategies employed by organizations such as One Love, Green Dot, and It's On Us, all of which utilize evidence-based research to develop healthy relationship best practices, provide bystander training, and support preventative sexual assault measures. We used insights from these organizations to create practical community tools for Siena, such as a campus engagement model prioritizing healthy-relationship education and a strategy for sustained student involvement in this work after our partnership concludes. Additionally, we mapped existing on-campus prevention initiatives, reviewed peer-institution outreach strategies, created student-facing events and resources, and designed social media messaging focused on consent, boundaries, reporting options, support services, and bystander intervention. As a result of our work to partner with several offices at Siena, this project found its home with the Student Life team in the Fall 2025 semester, which demonstrates that purposeful collaboration can make a broader impact on healthy relationship initiatives on a campus when utilizing a community-based approach.

Abstract Name: Improving GMM Clustering for Cyberattack Detection using log1p Feature Transformation

This project investigates how Gaussian Mixture Models (GMM) can be used to detect unusual or possibly malicious network activity across five different Zeek-based cybersecurity datasets. The main goal was to understand how different feature selections and preprocessing steps affect the quality of unsupervised threat detection. First, GMM was tested using only numerical features and experimentation was done with different

values of k and random seeds. The early results were weak, so an ablation study was performed by removing one numeric feature at a time to see which ones had the largest impact. Because numeric features alone still did not produce strong performance, experimentation was expanded to include several categorical network features, converting them into numerical values with PySpark's StringIndexer so they could be used by GMM. A second ablation study showed that the categorical features "proto" and "conn_state" were the most helpful for improving cluster separation. A log1p transformation was also used to reduce the effect of extremely large values in certain numeric columns, which noticeably improved the stability and performance of the model. After testing many combinations of both numeric and categorical features across all five datasets, the best final model reached approximately 99.9% detection accuracy when comparing clusters to ground-truth labels. These results show that careful feature selection, smart use of categorical data, and proper preprocessing such as scaling and log transformations can greatly improve unsupervised machine learning models. Overall, this project demonstrates that GMM, when combined with the right features and transformations, can be a powerful method for detecting abnormal behavior in large and complex network-traffic datasets.

Abstract Name: Expression of Genes in the bacterium *Pseudomonas* 20ei1 in Response to Co-culture with the Fungus *Aspergillus nidulans*

Some fungi produce harmful toxins that can impact the food supply and cause cancer and other public health issues. Understanding how bacteria respond to fungi at the molecular level can help to develop fungal control strategies. Can genes from the bacterium *Pseudomonas* 20ei1 be identified that are expressed at higher levels when co-cultured with the fungus *Aspergillus nidulans*? *Pseudomonas* 20ei1 is a locally isolated strain of bacteria that was used to inhibit growth of fungi (see: <https://doi.org/10.3389/fmicb.2024.1514950>). Quantitative real-time polymerase chain reactions (qPCRs) were used to compare gene expression in *Pseudomonas* 20ei1 grown alone or the presence of fungi (co-cultures). RNA was extracted from cultures 1, 2, 3, and 4 days after inoculation into two different growth media. RNA quality was verified by agarose gel electrophoresis before DNase treatment and cDNA synthesis. qPCR was performed with validated primers targeting genes related to biofilm formation, metal acquisition, regulatory signaling, and antimicrobial pathways. qPCR results show that *Pseudomonas* 20ei1 exhibits condition-dependent, differential gene expression when co-cultured with *A. nidulans*. Several genes were upregulated, including genes involved in copper and iron metabolism, antibiotic production, and production of extracellular enzymes. Genes for iron metabolism and antibiotics were expressed at elevated levels in two different growth media. Maximum expression occurred on different days after inoculation depending on the gene. Bacteria–fungus interactions strongly influence ecological dynamics, resource competition, and secondary metabolism within microbial communities. Because *Pseudomonas* 20ei1 shows clear transcriptional shifts when exposed to *A. nidulans*, future work will contribute to better understanding natural antagonistic interactions and could support new strategies for improving food safety and biological control.

Abstract Name: In No Time: Temporal Manipulation in Makrokosmos I

George Crumb (1929-2022) was one of the foremost American composers of the 20th century. While Crumb's oeuvre is characterized by rigorous treatment of musical elements, the composer reappropriates the modernist paradigm of music-making in service to romantic aesthetic sensibilities (Johnston, 2022). Crumb scholars find their typical analytical approaches confounded, thus requiring novel frameworks for the interpretation of his music. This study utilizes Johnston's novel approach to Crumb's music, where he positions the composer's work at the intersection of three aesthetic paradigms: modernist composition, romantic aesthetics, and postmodern deconstruction. This paper examines Crumb's Makrokosmos I, a four-volume set of pieces for piano, arguing that the composer's modernist-romantic syncretism dissolves linear time into a sensory suspension of the infinite present. I propose that, to achieve this temporal warping effect in Makrokosmos I, Crumb manipulates the relationship between metric and rhythmic parameters, emphasizes visual effect of circular and spiral imagery in his graphic scores, and foregrounds the concept of time by his choice of titles in several pieces in Makrokosmos I. When worrying about the future and regretting the past is a common mindset, embraced and practiced by many in our society, I posit that Crumb's music embodies temporal manipulation that projects the notion of "now" as the only time that exists. Ultimately, Crumb's music allows both performers and listeners to occupy, briefly, the infinite present.

Abstract Name: Beehive Health: Tracking Temperature, Weight, and Buzzing Frequencing with an Integrated Sensor Network

The purpose of this project is to develop a real-time beehive monitoring system for beehives located on the Edmonds College campus in Lynnwood, Washington. The system is designed to track key indicators of hive health, including temperature, weight, and buzzing frequency, using a sensor network controlled by an Arduino Nano microcontroller. Honeybee colonies are especially vulnerable during the winter, when sudden temperature drops, reduced food access, and behavioral changes can lead to colony decline. After the Edmonds College campus hive failed to survive last winter, we set out to develop an accessible, low-cost monitoring system capable of detecting early signs of hive stress. The selected metrics of temperature, weight, and buzzing frequency are strong predictors of colony stability because they reflect brood development, food availability, and overall colony activity. Our prototype successfully measured internal and external temperatures using DS18B20 digital thermometers, hive weight using load cells, and buzzing frequency using a MAX4466 microphone and Fast Fourier Transform (FFT) analysis. This system can highlight unusual trends, such as large temperature differences, drastic weight changes, or irregular buzzing frequencies. To enable timestamped, real-time data transmission and alert notifications, the prototype also includes a WiFi-enabled real-time clock module. The expected outcome of this project is a reliable, user-friendly, and open-source device that continuously collects accurate data and supports automated alerts. By simplifying hive monitoring and making the system affordable and scalable, the project aims to promote sustainable beekeeping and reduce colony loss.

Abstract Name: Structural Comparison of Dendrites and Spines in Adult-Born and Mature Granule Cells

Title: Dendritic Spine Analysis in Adult-Born vs. Mature Granule Cells Adult neurogenesis in the hippocampal dentate gyrus (DG) continuously adds adult-born granule cells (abGCs) to existing neural circuits, resulting in neurons with distinct dendritic morphology, spine dynamics, and synaptic integration compared to developmentally mature granule cells (mGCs). These structural differences influence key hippocampal functions, including pattern separation, memory encoding, and circuit remodeling. Dendritic spines, as primary sites of excitatory synapses, are critical for synaptic plasticity; their number and shape are essential for neuronal connectivity and information processing. Our study will investigate the morphological and dynamic differences between the dendrites and spines of abGCs and mGCs. Using confocal microscopy and semi-automated reconstruction software (Neurolucida 360), neurons were visualized and dendritic spines classified into thin, stubby, and mushroom types along proximal, medial, and distal dendritic segments. Quantification of spine density and turnover across developmental stages will reveal how abGCs, during early integration, transiently increase thin spine numbers and turnover, reflecting heightened structural plasticity relative to mGCs. Combining spine developmental staging with morphometric analyses enables detection of both qualitative and quantitative differences in dendritic structure and spine turnover between mGCs and abGCs. These findings will clarify the unique contributions of newly generated neurons to hippocampal function, particularly in learning and memory, and suggest that identifying these structural hallmarks may inform strategies to enhance neurogenesis or counteract hippocampal dysfunction in brain diseases.

Abstract Name: “How long will I keep having to try to find myself?": Narratives of Eastern European Jewish Women Immigrants in the United States

This paper is centered around the narratives of Jewish immigrant women who arrived in the United States during the late 19th and early 20th century. The project seeks to determine how the self-discovery of Jewish-American women is intertwined with the process of recounting their lives—both in written and oral accounts. The primary source base focuses on published novels, memoirs, oral histories, as well as unpublished autobiographies and accounts found in the YIVO archives. For women specifically, the United States offered opportunities in secular and non-secular education, allowing them to access new forms of introspection and narration of their own stories. The desire for education, family, independence, and intimate personal connections are preeminent in many of these narratives. Yet a desire for literacy stands out as it demonstrates that reading and writing itself provided access to identity recreation. The question of language is central to this project, as the decision to communicate in either English or Yiddish determined how women were able to construct their intersecting identities. Drawing on work in both immigration history and literary studies, this project builds on scholarship regarding assimilation and the role gender played in women's experiences of cultural adaptation. Exploring how the creation of the self is related to the processes of immigration, the intention is to account for the unique way that Jewish women experienced migration. Other scholars have chosen to make sharp distinctions between fiction, memoir, autobiography, diaries and other mediums, but the methodology of this paper unites genres of personal accounts. The paper intends to demonstrate how Jewish-American women's narrations in various genres have consistent patterns despite the differences in their medium of expression. These patterns will illuminate the unique ways that immigrant narratives depict the self discovery process that these women experienced, especially in terms of education, intimate relationships, and language.

Abstract Name: Stress in First Responders

Due to their high occupational risk for experiencing traumatic events, current research suggests that first responders have higher prevalence rates of post-traumatic stress disorder (PTSD) as compared to national averages and are at a higher risk for a multitude of mental disorders. Despite this, current research investigating the mental health of first responders is limited to the point of lacking crucial evidence to support recommendations for care and suffers from an over-representation of White participants, with only one study found in a search to investigate minority first responders. Thus, the aim of this project is to investigate the prevalence of secondary traumatic stress, as in becoming traumatized due to being exposed to details of trauma by others, and vicarious traumatization, as in a noted shift in perspective and worldview because of engaging with those exposed to trauma. Potential differences in the experiences of majority and minority first responders in these variables and attitudes towards mental health seeking will also be investigated. This study

will involve the recruitment of first responders, defined as firefighters, law enforcement officers, emergency dispatchers, and emergency medical technicians (“EMTs”). Their experiences with trauma relating to calls they have either been directly or indirectly involved in will be captured via an anonymous online survey that will seek to measure PTSD symptomology, vicarious and secondary trauma, and attitudes toward treatment. Data will be collected from November 2025 until January 2026. The researcher hopes to identify recent trends in symptomology and experiences of racial/ethnic minorities in the first responder population. This study has been approved by Adelphi University’s Institutional Review Board on October 13th, 2025, as Exempt.

Abstract Name: “Hey, Siri, Play ‘Hasta Que Te Conocí’ By Juan Gabriel”: Automatic Speech Recognition (ASR) Systems (In)Accuracy In Spanish-English Bilinguals

Automatic Speech Recognition (ASR) systems have been changing human interactions with technology. Systems like Alexa, Google Assistant, and Siri are popular, and for many, have become an integral part of their lives, helping users to complete tasks using voice commands. Even though these ASR systems have improved, many times they may not be accurate, particularly while interacting with nonstandard accents. In this sense, it is argued that the ASR systems still lack accuracy in understanding different accents. Users' complaints and experiences have been shared in social media or online customer services company blogs. In recent years, research on the accuracy of ASR from Amazon, Apple, Google, IBM, and Microsoft display greater word errors on non-native accents of English, as well as some regional dialects notably the African American English in contrast with a standardized, monolingual accent. This can be due to a lack of training datasets that are representative of those populations –for instance, there is predominant sampling from white, affluent, monolingual English communities. So, if ASR systems are currently showing their struggles interacting with some speakers with a non-standardized, non-monolingual accents, would ASR also struggle to understand and follow commands from bilinguals who speak Spanish or English with a non-standardized, non-monolingual accent? Overall, what have been the experiences of Spanish-English bilinguals with ASR systems? Although numerous articles and websites talk about how ASR systems work and their general usability, very few examine if the speech of these bilinguals –whether they are L1- or L2-Spanish speakers– contributes to the (in)accuracy of these systems. This in-progress study aims to address this gap by analyzing the speech of Spanish-English bilinguals as they give commands and read from a short paragraph to ASR systems in both languages. This research signifies advancing towards technology access for understudied populations, for which datasets may be deficient.

Abstract Name: The Effect of Green and Red Light on the *Manduca sexta*

Manduca sexta, also known as the tobacco hornworm, is a widely-used experimental subject that has helped us for more than 40 years in many areas of insect biology, such as neurobiology, chemical sensing, and immunology. Therefore, it was a beneficial test subject for our research. *Manduca sexta* is a pest found mostly on tomato plants but can also be found on other plants. Finding out which light *Manduca sexta* consumes less food in could help with managing their pest-like tendencies. Understanding how light affects their foraging tendencies could help us apply more eco-friendly methods that aren't harmful to crop growth without relying on pesticides. Hornworms were placed on arugula plants under different wavelengths of light and allowed to forage. Hornworms in red light lost weight and the ones under green light gained weight. This may be due to different light colors matching or not matching their search image. A search image is a mental image that tells the organism what is safe and what isn't to eat. This means that *Manduca sexta* prefers green light since they ate more in this light because the search image was matched, compared to the red light, where the search image was not matched. This research is important because it is able to give us an ethical and easy way to reduce the amount these pests consume and help us agriculturally, without harming the organism or the plant. Red light could be more useful for the plant, it allows more photosynthesis to happen, so it wouldn't only stop *Manduca sexta* from eating the plant, but also allow the plant to grow more.

Abstract Name: Gastrointestinal Motility Dysfunction in Down Syndrome Bilal Naveed, James Fune, James Kang, Andrew George, and Hamid I. Akbarali Department of Pharmacology and Toxicology, Virginia Commonwealth University

Patients with Down Syndrome (DS) (the result of an extra copy of chromosome 21) experience significant gastrointestinal (GI) issues, specifically constipation. However, the mechanism for the GI dysfunction in DS remains unclear. The Ts65Dn mouse carries an extra copy of chromosome 16 (the mouse equivalent of human chromosome 21), providing a model for studying GI dysmotility. In this study, we measured GI motility in-vivo and in ex-vivo colonic tissues. For total GI transit, a non-absorbable fluorescent dye was gavaged, and the time to first expulsion of a fluorescent fecal pellet was recorded. The contractile patterns in the two cohorts were determined ex-vivo using the gastrointestinal motility monitoring system (GIMM). After dissection, each colon was placed into a temperature-controlled water bath perfused with oxygenated Krebs solution, and contractions were recorded in 30-minute bins to generate spatio-temporal maps. Colonic migrating motor complexes (CMMCs) were recorded as full peristaltic contractions or partial contractions that did not exceed 50% distance. Whole GI transit was significantly faster in DS mice than their disomic littermates. The time to first expulsion for disomic mice was 99.2 ± 16 minutes ($x \pm SD$; $N=16$) and 76 ± 15 minutes ($x \pm SD$; $N=15$) for DS mice ($p = 0.0004$). In ex-vivo studies, CMMCs were recorded for 30 minutes under baseline conditions, followed by perfusion with acetylcholine ($1 \mu M$) for another 30 minutes. The colons from DS and disomic mice showed a similar number of CMMCs under basal conditions, while acetylcholine significantly increased CMMCs in DS mice compared to disomic littermates, reaching $138 \pm 6\%$ of baseline versus $120 \pm 7\%$, respectively. These studies show significant differences in gastrointestinal motility in trisomic vs. disomic mice, consistent with clinical findings. Further studies to determine whether these differences are due to pacemaker activity are underway. Supported by NIH HD114125.

Abstract Name: Cross-Study Analysis of Vagus Nerve Stimulation-Induced Cortical Plasticity in the Motor Cortex

Vagus nerve stimulation (VNS) is a promising tool for enhancing neuroplasticity. VNS has demonstrated success in improving motor recovery in stroke patients, but some individuals do not respond to treatment. Understanding the variables underlying these discrepancies is crucial for optimizing therapeutic outcomes. Preclinical models pairing VNS with motor training offer a directly translatable approach to investigate these factors under controlled conditions. Previous studies have shown that VNS expands movement representations in the primary motor cortex, often following an inverted-U pattern of stimulation intensity. However, differences in experimental models, stimulation parameters, and neuromodulatory conditions across studies hinder conclusions about which factor combinations best drive cortical plasticity. In this review, we conducted a cross-study analysis of thirteen preclinical rodent studies (2012-2024) that examined the effects of VNS on motor cortex plasticity. We quantified variable overlap between stimulation intensity, timing, task type, and neurochemical manipulation. Using scatter plots and two-tailed t-tests with multiple comparisons, we identified consistent patterns showing that moderate-intensity VNS at 0.8 mA is most effective at driving motor map expansion when paired with behavior. We also identified gaps in the literature where variables have not been tested in combination; for example, while cholinergic lesions block VNS-induced plasticity, it remains unknown whether higher intensities might overcome this effect. Our findings consolidate existing results and highlight unexplored intersections between key variables. Future studies should aim to test these missing combinations to provide deeper insight into the mechanisms underlying VNS therapy, ultimately increasing responder rates and expanding its therapeutic potential in motor rehabilitation.

Abstract Name: Impact of Flanking mRNA Mutations on Bicc1-RNA Binding Specificity

Bicaudal-C (Bicc1) is an evolutionarily conserved RNA-binding protein essential for embryonic development. In our model organism, embryos of the frog *Xenopus laevis*, disruption of Bicc1 function leads to pronounced anterior and posterior anatomical defects. Bicc1 regulates development by binding specific mRNAs and repressing their translation. The goal of my project is to understand how Bicc1 selectively recognizes and binds its target mRNAs. Bicc1 contains five structural domains, and current observations suggest that the KH2 domain—and its conserved GKGG motif—is critical for specific mRNA recognition across species. Using AI-generated structural predictions from AlphaFold 3 and PyMOL, we recently identified and partially confirmed key amino acids within the KH2 domain that directly contact target mRNAs, including the well-characterized Bicc1 targets *dand5* and *cripto*. These residues within the KH2 domain make direct contact with an RNA region that contains a conserved GAC sequence, a motif consistently found in Bicc1-interacting mRNAs. Building on these findings, I am using wild-type *Xenopus* Bicc1 protein to test how variants of Bicc1-interacting mRNAs respond to flanking mutations surrounding

this KH2-contacting region. Using electrophoretic mobility shift assays (EMSAs), I first qualitatively—and later quantitatively—measure changes in RNA–protein binding to determine how these mutations affect Bicc1’s ability to recognize its mRNA targets. Results from these experiments will provide new insight into how Bicc1 interacts with mRNAs, helping us understand how mRNA structure contributes to Bicc1-mediated translational repression during embryonic development.

Abstract Name: Sleep Hygiene and Well-Being in Older Adults: A Pilot Study

Sleep Hygiene and Well-Being in Older Adults: A Pilot Study Maya Ndjarakana, Anaya Mitra, MPH, PhD Psychology Older adults frequently report poor sleep. This pilot study examined the sleep hygiene habits of older adults, assessing whether behavioral interventions—such as increased physical activity or reduced caffeine intake—could improve sleep quality and quantity. Participants aged 55 and older were recruited at a senior living facility in Minnesota. Participants completed a pre-survey on demographics, caffeine consumption, physical activity, and sleep behaviors. They then selected an intervention—either increasing physical activity or modifying caffeine intake for 2 weeks. The post-survey measured changes in sleep hygiene, quality, and duration. Descriptive statistics, paired t-tests, and Pearson correlations conducted to examine relationships between physical activity, BMI, and sleep metrics. Fourteen participants completed the pre-survey; only 6 participants completed the post-survey. Most participants identified as female (75%) and White/European American (92%). Their average BMI was 24.57 (± 5.76). Most participants consumed caffeine (78%) - primarily coffee. On average, participants reported sleeping 7.9 hours (± 3.3) per night. The mean sleep quality rating (1= Very Poor, 5 = Very Good) was 3.5 (± 1.2). There were no significant differences in the sleep quality, sleep quantity, or demographic profile between those who completed the pre- and post-surveys. The most commonly selected intervention was the addition of a 15-minute walk to their daily routine. The absence of measurable change between the pre- and post-survey results may be due to several factors: the selected intervention may have been ineffective at improving sleep, the two-week time frame may have been too brief to detect change, and it is important to note that baseline sleep was relatively good for the majority of our participants, which left limited room for improvement. Future comparisons will be made with existing data on college-aged participants to explore age-related differences in sleep behavior.

Abstract Name: The Limits of Sitcom Progressivism: A Rhetorical Critique of Modern Family

This paper examines the ABC television series Modern Family (2009-2020) through a critical media literacy framework to evaluate the limits of LGBTQ+ representation in mainstream sitcoms. Although the series was widely praised for normalizing a married gay couple on network television, its portrayal of Mitchell

and Cameron reveals the compromises necessary to produce “progressive” content within corporate media structures. Drawing from the ideas of the familiarity-novelty continuum and codes and conventions, this rhetorical critique argues that while *Modern Family* expanded LGBTQ+ visibility, it simultaneously constrained queer characters through heteronormative gender roles, domestic stereotypes, and the structural demands of sitcom storytelling. *Modern Family* reinforces a core principle of critical media literacy: that media texts are never neutral, but instead carry embedded values and points of view. My analysis situates *Modern Family* within broader scholarship on representation, media production, and the packaging of queer identities for straight, middle-class audiences. Using close textual analysis of key episodes and scenes, the project examines how network expectations shape character behavior, relational dynamics, and the boundaries of “acceptable” queerness. The method includes rhetorical analysis, with specific attention to character coding and narrative framing. The findings of my paper indicate that the show’s progressive appearance relies on familiar sitcom tropes, husband/wife binary and rapid conflict resolution, that ultimately reinforce, rather than disrupt, dominant cultural norms. By balancing novelty (gay marriage) with familiarity (traditional gender roles and sitcom conventions), *Modern Family* produces a representation that is “acceptable” but limited. My analysis concludes by arguing that the series exemplified the broader challenges of achieving meaningful representation within network television.

Abstract Name: Verifying Targeted Chemogenetic Manipulation of Hypocretin Neurons in HCRT:Cre Rats through Immunohistochemistry

Hypocretin/orexin (HCRT) is a neuropeptide produced primarily in the lateral hypothalamus and has been proven to be essential for regulating motivated behavior. Historically, efforts to examine the importance of HCRT have relied mainly on pharmacological approaches to block or activate HCRT receptors. Here, we set out to establish methods to selectively activate or inhibit HCRT neurons themselves. We used HCRT:Cre transgenic rats that express the Cre recombinase enzyme only in HCRT neurons. We allowed selective targeting within HCRT neurons to express Cre-dependent DREADDs (Designer Receptors Exclusively Activated by Designer Drugs) for activation or inhibition of HCRT neurons. We injected HCRT:Cre- and HCRT:Cre+ rats with either a Gi or Gq DREADDs virus tagged with fluorescent mCherry. To assess specificity of our approach, we first quantified the co-expression of mCherry tag and HCRT peptide-1 via immunohistochemistry. As expected, we found co-expression of HCRT-1 peptide and mCherry only in HCRT:Cre+ rats, with HCRT:Cre- rats displaying none. Next, to determine the degree of HCRT neuron activation, we injected HCRT:Cre+ and HCRT:Cre- rats with a Gq DREADDs virus and treated with deschloroclozapine (DCZ) 3 weeks after virus injection. Brain slices containing the lateral hypothalamus were analyzed for co-expression of HCRT peptide 1 and the immediate early gene cFos—often used as an index for neuronal activation. Surprisingly, we determined that DCZ administration did not significantly increase cFos in HCRT neurons, with no differences in co-expression of cFos and HCRT-1 peptide between HCRT:Cre+ rats expressed Gq DREADDs and HCRT:Cre- rats. Together, our studies show DREADDs can target specific neurons, but reliable activation using this approach was not achieved. Future studies will be needed to assess other measures of neuronal activity and potentially other DREADDs ligands to determine if we can manipulate the activity of HCRT neurons.

Abstract Name: Reimagining Unconventional Infrastructure as Social and Ecological Connectors

This project investigates how unconventional infrastructure can be turned into adaptive social and ecological systems. Infrastructure is never neutral, the most utilitarian networks even shape how people move, gather, and access opportunity. These underused thresholds contain latent capacity to serve as civic and ecological connectors that are responsive to both environmental conditions and the social contexts of surrounding communities. The research examines how design can turn these systems into frameworks that adapt to changing climates and social needs. Situated near the Port of Mobile, Alabama, the site frames the study. This project analyses infrastructure life cycles through three temporal phases, Conception, Mid-Life Crisis, and Afterlife. Each of these phases representing a distinct phase in a system's progression over time. Conception investigates projects that are intentionally constructed to satisfy both technical and social functions. Mid-Life Crisis examines current systems experiencing decline or fragmentation, considering interventions needed to restore their full civic purpose. Afterlife envisions obsolete infrastructures transformed into fully renewed public spaces, re-established through creative collaboration with the community. The project integrates these aspects into a systems-based framework for ecological resilience and adaptive reuse by employing precedent mapping, iterative design, and spatial and typological analysis. It reveals parallels between infrastructure and social networks concerned with accessibility, food security, and environmental stewardship, highlighting the reciprocal influence between infrastructure and communities. In conclusion, this study redefines infrastructure not as a static object but as a living medium, both as an archive and an agent of change. It positions these systems as sites to record change, sustain community, and support the shared ecological futures. By recognizing the social and environmental components of infrastructure, the project aims of a more inclusive, resilient civic frameworks that change. In changing can evolve along with, their users' landscapes and communities.

Abstract Name: Investigating the Role of Human Milk-Derived Exosomes in Oligodendrocyte Progenitor Cell Proliferation, Differentiation, and Myelination

Oligodendrocytes are specialized glial cells in the central nervous system responsible for producing myelin, the insulating sheath that enables rapid and efficient neural signal transmission. Oligodendrocyte progenitor cells (OPCs) are the precursor cells that proliferate, migrate, and differentiate into mature oligodendrocytes during early brain development. Proper regulation of OPC development is essential for healthy white matter formation, and disruptions to this process are associated with long-term cognitive and neurological impairments. While early-life nutrition is known to influence neurodevelopment, the molecular mechanisms linking nutrition to myelination remain poorly understood. Human milk contains extracellular vesicles (EVs), nanoscale lipid particles enriched with proteins and microRNAs that can modify gene expression in target cells. This study investigates whether human milk-derived EVs regulate OPC proliferation, differentiation, and early myelination in vitro. Primary OPCs were isolated from neonatal mouse cortices using enzymatic dissociation and density gradient centrifugation, then seeded on poly-D-lysine-coated culture surfaces. Cells were treated under four experimental conditions: growth factor-free control, growth factor control (PDGF-AA and bFGF), low-dose EV (50 µg), and high-dose EV (100 µg). Cell proliferation was quantified using EdU incorporation and Ki67 immunostaining. To assess lineage progression, differentiation was induced

using T3-containing media and evaluated using markers including PDGFR α , O4, CC1, and Sox10. Functional myelination was examined through neuron-OPC co-culture followed by immunostaining for myelin basic protein (MBP) and the neuronal marker NeuN. Preliminary results demonstrate a dose-dependent increase in total OPC number following EV treatment, with the highest proliferation observed in the high-dose EV condition relative to both growth factor and negative controls. Ongoing analyses aim to determine whether EV exposure also accelerates OPC differentiation and enhances early myelin formation. Future studies will focus on identifying specific EV-associated microRNAs. Understanding this mechanism may inform future therapeutic strategies for demyelinating conditions of the central nervous system, including multiple sclerosis.

Abstract Name: Why Can't We All Laugh Together? A Study On The Utilization of Humor For Mediating Conflict During Political Conversations

Since the 2016 presidential election in the United States, it's common to see relationships tainted by opposing political ideologies and increased political polarization. While strife between humans has been in occurrence since the beginning of man, the hatred and violence developed from centuries of disagreements have greatly intensified over the last 10 years. Humor is a powerful force that can foster positive engagement and build bonds between people. Humor signifies closeness and is associated with intimate, shared experiences. Moreover, a prior relationship is not required for humor to facilitate connection. Given its social power, humor may play a key role in conflict resolution. This raises a question about whether humor might be able to calm political disagreements. Referencing Blake and Mouton's (1964) conflict strategy model and the understanding of universal implications of humor, we examine videos uploaded to YouTube consisting of public conversation held by American liberals and conservatives discussing disagreements over American politics. We explore if there is an effort by either party to ameliorate conflict with humor. Conversations are coded for whether and how humor is used as a type of conflict resolution and if the two parties are able to come to a position of agreement as a result of the use of humor. From inspecting bilateral political debates, we expect to find that humorous speech is used as an attempt to defuse argumentative discourse specifically when there is intent to create companionship. This research attempts to find whether humor can serve to reintroduce partnership in the context of conflict. The results of this research have the potential to serve as a reminder that humans have a natural drive for connection and how humor can be used as a form of resilience against manmade social differences especially within personal relationships and communities.

Abstract Name: A novel device for high-throughput phenotypic screening of schistosome miracidia enables identification of transient receptor potential (TRP) channels modulators that impact miracidia behavior

Schistosomiasis, a neglected tropical disease caused by three parasitic flatworm species, including *Schistosoma mansoni*, relies on freshwater snails as intermediate hosts. Interrupting the parasite's ability to locate snails could provide a novel strategy for disease control. Praziquantel (PZQ) is the current treatment of choice for human infections, and it exerts its effect by targeting transient receptor potential (TRP) channels on the parasite, debilitating the worms and leading to clearance by the host immune system. Despite its effectiveness in eliminating adult parasites, treated individuals remain susceptible to reinfection. Interestingly, TRP channels are classically recognized as key metazoan sensory receptors, involved in reception of a variety of chemical cues, though the mechanism of action of PZQ is not known to be related to sensation. Since TRP channels have been shown to be a rich source of anthelmintic drug targets, we hypothesized that they could also be targeted to disrupt the sensory behaviors involved in miracidia infection of snails. In this study, a high-throughput phenotypic screen was developed and used to identify bioactive compounds targeting the transient TRP receptors in miracidia. A custom 96-well acrylic device – the ScreenChip – was designed for simultaneous wide-field imaging by a custom high-resolution, multi-camera imaging device. Miracidia were treated with 10 μ M of compound, and the impact of each compound on miracidia behavior was assessed to identify potential hits. Our recording system and downstream analytical pipeline enabled precise observation of miracidia motility and orientation, allowing identification of compounds that disrupt general movement and chemokinetic behaviors. Preliminary findings suggest that TRP channel modulators play a role in altering miracidia navigation, offering a promising avenue for disrupting the parasite's life cycle. Future investigations will establish the effective concentrations of hit compounds and test for potential inhibition of snail host-seeking, penetration, and infection.

Abstract Name: Case Study of Lacing Joinery

The technique of lacing joinery, which has its roots in centuries of architectural and interior design traditions from various cultures, involves weaving or tying materials together to produce flexible and stable connections. Lacing joinery is a reflection of both technological advancement and cultural adaptability. This study analyzes how this joinery technique can be implemented at multiple spatial scales, ranging from the small artifact level to large-scale spaces like personal and social spaces. The primary objective of this research is to investigate the versatility of lacing joinery by analyzing its use from broad spatial patterns down to small-scale connections. The ability of interlocking patterns to provide cohesive spatial integration across different design scales is examined in this study. By converting lacing approaches into physical objects such as a native american soul catcher, using lacing to join beams and columns in an enclosure design, and broader spatial linkages in personal and social space by relating joinery technique with interlocked and adjacent spatial relationships. The research reveals that lacing joinery can reliably produce both visual and structural links in plans and sections of personal and social spaces by arrangement of walls, level changes, and circulation. The inherent flexibility and adaptability of lacing joinery can unite different components within an interior space, giving a sense of continuity and cohesiveness. In its conclusion, this study emphasizes lacing joinery as a useful tool for modern interior design, providing rich visual language. By integrating traditional craftsmanship with modern architectural practice, lacing joinery provides a framework for coherent and interesting interior settings. The findings emphasize its potential to inspire new avenues in design, where joinery techniques and interconnection become a method of achieving both structural integrity and creative expression.

Abstract Name: Mechanisms of Developmental Regulation in *Drosophila melanogaster*

Hox genes determine the segmental patterning of vertebrate embryos from anterior to posterior. These genes aid in cellular differentiation, the process of determining the function of a cell through modifications to gene expression. Hox genes are involved in the development of many human cancers, making this research relevant to furthering cancer identification and treatment. The purpose of this research is to uncover the mechanistic regulation of Hox genes in the model organism *Drosophila melanogaster*. Previous research has concluded that two groups of proteins, Polycomb Group (PcG) and Trithorax Group (TrxG), inhibit and promote Hox gene expression, respectively. Preliminary models of Hox gene regulation propose that a prominent PcG protein, Scm, forms large aggregates on Hox genes, inhibiting their expression in improper segments. Two proteins of interest, tna and velo, alter the aggregate size and subsequent effectiveness of Scm polymerization and silencing. It is not understood the extent to which tna and velo alter the activity of Scm nor the interactions between the proteins. Uncovering the regulation of Scm contributes to an understanding of Hox genes and developmental patterning. To uncover the interactions between these proteins and DNA, genome analysis will be performed using chromatin immunoprecipitation (ChIP). This data will indicate the DNA targets of the proteins of interest, beginning the elucidation of their interactions. To dive further into the effects of tna, velo, and Scm on Hox genes, RNAi will be used to evaluate misexpression in embryos. When Scm is eliminated using RNAi, segmentation is altered. Additionally, the absence of Scm is lethal to the developing embryo, demonstrating the necessity of proper Hox gene expression. Similar experimentation will be used to study the phenotypes of tna and velo RNAi-expressing embryos. Phenotypic abnormalities will indicate the significant impact of the proteins tna and velo on Hox gene expression.

Abstract Name: Testing an Intervention to Decrease Affective Polarization and Increase Interpersonal Trust Utilizing the Theory of Dyadic Morality (TDM)

Current literature surrounding affective polarization indicates that polarization threatens democratic stability, political compromise, and may be linked to political violence. Research surrounding potential interventions for polarization remains limited but suggests that exposure to similarities, establishing a common intergroup identity, and positive contact may reduce polarization. This study attempted to test an intervention to reduce polarization by exposing the experimental group of participants to the Theory of Dyadic Morality (TDM) which highlights the similarities in individual moral formation across cultures. Given the role of morality in political ideology, emphasizing the commonality in human moral formation among individuals may help to reduce polarization. A sample of Introduction to Psychology students (N = 55) were randomly assigned to the TDM condition (n = 27) or the control condition (n = 28), and their levels of affective polarization and interpersonal trust were measured via QualtricsXM. The results of independent samples t-tests and Pearson correlations were nonsignificant but emphasize the importance of continued research surrounding the underpinnings of polarization and potential interventions to mitigate affective polarization. This study also utilizes a recently developed measure for affective polarization, which may prove fruitful in understanding the underlying mechanisms in future polarization research.

Abstract Name: Brotherhood: The Role of Men's Groups in Reducing Loneliness and Fostering Connection

Loneliness is a growing public health concern with significant effects on mental and physical health, and a mortality risk comparable to smoking fifteen cigarettes a day. Although solutions-based research is extensive, evidence on their long-term effectiveness remains limited. To address this gap, I conducted a case study in Bali, Indonesia to examine whether long-term participation in emotionally open men's groups offers a sustainable solution to loneliness. While loneliness affects everyone, my research focuses on men because they generally face under-addressed loneliness. Men also underuse formal health services due to social stigma and masculine norms, making men's groups a potential, acceptable, and accessible option. I conducted research via fifteen semi-structured interviews with men of various ages and backgrounds who had regularly participated in a men's group for at least three months. I also gathered data through field observations and autoethnographic journaling. Data were analyzed using qualitative thematic analysis informed by Self-Determination Theory (SDT) and Social Identity Theory (SIT). Findings indicate that sustained participation reduces loneliness, deepens belonging, strengthens everyday capability, and fosters a shared identity that normalizes emotionally honest support seeking. Participants reported increased social connection and a stronger sense of volition, with benefits extending into family, work, and community life. The findings suggest that free and easily accessible men's groups are a readily replicable model that can reduce loneliness in men, address SDT needs, and offer a practical foundation for developing peer-led support pathways, especially for long-term members. These findings could be used by public health services, educational institutions, and community organizations to implement this sustainable intervention for loneliness reduction. While longitudinal follow-ups and further research into variable facilitation across groups are needed, this study lays a foundation for further developing replicable models of men's groups that communities, community leaders or individuals could create themselves.

Abstract Name: Climate Change in the Greater Yellowstone Ecosystem and its Impacts on Black Bears

The Greater Yellowstone Ecosystem (GYE) is a biodiverse region centered on Yellowstone National Park, encompassing areas in Wyoming, Montana, and Idaho. This area is home to a diverse array of vegetation and animal species, encompassing mountains, forests, valleys, rivers, and numerous geothermal-rich areas. The climate in the region is generally considered temperate, comprising four distinct seasons. This study utilized long-term temperature and precipitation data from stations within and around the GYE to investigate the degree to which the climate is changing in the region. The study used precipitation, snowfall, maximum temperature, minimum temperature, and mean temperature data. Statistical analysis was used to determine how each of those variables was changing, as well as to determine if any of those changes were statistically significant. This climate data analysis serves as the primary metric to examine changes in black bear (*Ursus*

americanus) behavior across the region. Behavioral changes include alterations in hibernation habits, heightened human-bear conflicts, and the general movement of bears on time scales of days, months, and seasons. While black bears are a resilient species with many food source options, climate change could still alter some of their behaviors in the GYE.

Abstract Name: Observing the Impact of Hamline University's Infrastructure on Bird Populations

In recent years, anthropological and environmental inquiry has sought to document the relationship between the built human environment and bird populations. The research objective is to determine the impact of Hamline University's infrastructure on local bird populations. In this study, the researcher compiled current and historic data on bird populations in Minnesota along with self-conducted surveys to establish a baseline for their community. The self-conducted surveys documented any window collisions or bird deaths on their campus, prioritizing the development of proper survey methods for future research. This allowed for further exploration of how the infrastructure of buildings influences the population of birds. Through conducting anthropological work, they have used ethnographic research methods in attempts to create a holistic approach, focusing on the human-created effects of declining bird species. This study found that the highest amount of bird strikes occurred on buildings with large windows and high amounts of trees or greenery near the perimeter. Through their bird observations, they found three deceased birds. Two were non-native bird species, and the third was an immature robin presumed, at the time of death, to be unfamiliar with its surroundings. To achieve the research objective, the researcher collected data that pinpointed buildings where mitigation is essential, thereby creating a building mitigation plan. This project has collaborated with another student conducting research focused on mitigation strategies, raising awareness about the declining bird population, and fostering conversations among other college campuses, in hopes that both projects would be able to evaluate and mitigate Hamline University's campus. Using an anthropological approach, we can understand the ways in which humans influence our environment and affect the world around us.

Abstract Name: Malign Influence in Latin America: The Looming Implications of Chinese Adventurism in Panama

This research paper aims to examine the history and implications of China's unconventional geopolitical agenda in Panama and for the United States' national security and ability to reinforce diplomatic ties in the Western Hemisphere. As great power competition between the US and China surges, the homeland's geographical barriers become increasingly less withstanding of the influencing forces its enemies are exercising. The persistent and growing threat is no longer depicted by troops and military strength alone, but by subtle, seemingly noninvasive tactics. China is taking advantage of the US's receding influence in the Global South, primarily in Latin America and the Caribbean (LAC). Opportunistically filling in the void often left after sporadic US involvement in Central and South America, China has implemented a patient

geopolitical strategy set on diminishing the US's longstanding economic and political position in the region. Not only benefitting the ongoing competition on economic and influential fronts, China's involvement with the US's backyard reveals detrimental implications for power projection, national security, intelligence and data privacy, and diplomatic resilience and stability. With an alarmingly expanding presence, China is capable of choking American influence and bases of relations with historical and longstanding LAC allies. Compiling information from various think tank articles, national threat assessments, trade reports, and Department of Defense statements, the paper will provide a cohesive outlook on China's strategy to encroach on the US, coupled with policy recommendations to address the potential implications of Chinese influence in Panama. China's expansionist policies disguised as economic support and infrastructure development pose a significant threat to the US' economic, military, and diplomatic pursuits in and around the region. The United States and its governing body are urged to reevaluate foreign policy directed towards LAC to secure the nation's interests and defend its intelligence apparatuses.

Abstract Name: Phycobiliprotein Biosensors for Critical Mineral Detection

Metal contamination from industrialization poses a persistent environmental challenge, affecting water, soil, plants, animals, and humans due to toxicity and bioaccumulation. Rapid, low-cost detection strategies are needed, particularly in remote areas where conventional methods are slow and require specialized instrumentation. Cryptophyte phycobiliproteins (PBPs) are water-soluble, brightly colored proteins with strong fluorescence in the visible range, making them promising candidates for metal detection. In this project, purified PBPs from *Hemiselmis pacifica* (producing PC-577 protein) and *Proteomonas sulcata* (producing PE-545 protein) were exposed to varying concentrations of metals, including Cu^{2+} and Zn^{2+} , over different time intervals. Fluorescence changes were monitored using kinetic plate-reader measurements to assess how metal exposure impacts the protein optical properties. Dialysis experiments were performed to test whether metal binding to the PBPs is reversible by monitoring for spectral changes using both absorbance and fluorescence spectrophotometers. Preliminary results indicate that Cu^{2+} causes significant fluorescence quenching of both PC-577 and PE-545, while other metals such as Zn^{2+} do not. This suggests that PBP fluorescence can be used to distinguish certain metals. This study also shows that reversible binding may be possible under low metal concentrations, indicating that PBPs can be used over many cycles. This work establishes a foundation for developing PBP-based, aqueous-phase biosensors for rapid, specific, and environmentally friendly detection of metals in water.

Abstract Name: Effect of Clomiphene citrate exposure during maturation on gene expression in

parthenogenetic porcine embryos.

The use of in vitro embryo production within the livestock industry has allowed for selection of superior genetics while decreasing generation length. A major contributor to inefficiencies during in vitro maturation (IVM) is the accumulation of reactive oxygen species (ROS). Exposure of porcine oocytes to Clomiphene citrate (CC), a selective estrogen receptor modulator, during IVM reduces ROS and alters genetic pathways. To determine the genetic effect of CC exposure during maturation on resulting parthenogenetic embryos, we collected embryos at 60 hours post activation. RNA was isolated from groups of parthenogenetic embryos generated from oocytes matured in the presence or absence of CC. Then, complementary DNA (cDNA) was synthesized. To explore the potential genetic effects of CC exposure, we compared the expression of the cell-to-cell communication gene Gap junction alpha-4 protein (GJA4); the early embryo developmental gene, Bone morphogenetic protein 15 (BMP15); and genes essential in fertilization, Zona pellucida glycoprotein 2 (ZP2) and Zona pellucida glycoprotein 3 (ZP3). There was no difference in the expression of GJA4 in the CC treated embryos (1.824 ± 0.04956 fold expression) when compared to the control embryos (1.578 ± 1.053 fold expression, $p=0.1184$). ZP2 was found to be expressed significantly lower in the CC treated embryos (0.1277 ± 0.0210 fold expression) when compared to the control embryos (1.038 ± 0.2017 SD, $p=0.0012$). Similarly, ZP3 was found to be expressed significantly lower in the CC treated embryos (0.1224 ± 0.05846 fold expression) when compared to the control embryos (1.229 ± 0.5789 fold expression, $p=0.0240$). BMP15 was found to not be differentially expressed in the CC treated embryos (0.6163 ± 0.2905 fold expression) when compared to the control embryos (1.235 ± 0.5798 fold expression, $p=0.3398$). These results suggest that CC exposure during maturation alters the expression of selected genes that potentially influence embryo health.

Abstract Name: Fish, Food, and Flow: Algal assemblage response to the presence and absence of grazers in intermittent rivers in Texas.

With climate warming, the duration and frequency of drought events is increasing in rivers worldwide. Intermittent droughts can disrupt river connectivity and cause water stress for biological communities, including algae and their grazers. Changes in temperature and flow dynamics can lead to changes in algal assemblage composition and abundance, as different species have different tolerances of environmental parameters. Grazers, like fish and other aquatic insects (macroinvertebrates), feed on algae, especially diatoms, which are rich in lipids. However, fish may be sensitive to warmer waters and river connectivity. This project aims to understand fish-grazer impact on algal assemblages in intermittent rivers in Texas. If fish graze on macroinvertebrates, algal abundance could increase, or species composition (> diatoms) could shift due to release from grazing pressure. In contrast, fish removal could increase grazing pressure from macroinvertebrates, leading to a decrease in algal abundance, and nutritious algae like diatoms, and an increase in grazer-resistant algae, like cyanobacteria. We collected algal samples from river pools with and without fish grazers during wet (October) and dry (July) periods in 2024. We analyzed algae on a light microscope to determine 'who' was there, and then with a fluid imaging particle analyzer (FlowCam®) to determine the relative abundance of major groups (cyanobacteria, diatoms, green or red algae). Preliminary results indicate that mucilaginous cyanobacteria filaments and diatoms dominated in the presence and absence of grazers, and under both wet and dry conditions. The mucilage-rich cyanobacteria filaments likely provide structure for the fine calcium-carbonate particles present in these rivers. Diatom relative abundance was higher with grazers present under both wet and dry conditions, suggesting a release of grazing pressure

from macroinvertebrates. This suggests that Texas rivers may be adapted to warm conditions and flow changes, but shifts in fish distribution could alter the quality of algae available to foodwebs.

Abstract Name: How Shifting Views Regarding Immigrants/Immigration in America Affects Immigrant Students' Ability to Succeed in Their Education.

As immigration enforcement has expanded in the United States over the past decade, many immigrant communities have experienced increased fear, stress, and uncertainty. This project explores how this enforcement climate affects immigrant college students' academic experiences. The main question is: How does stress related to immigration enforcement influence immigrant students' ability to succeed in school, including their grades, attendance, and overall focus on their studies? To answer this question, the project reviews recent research and reports published in the last 10 years on immigration policy, enforcement activity, and student outcomes. The review will look for studies that describe how enforcement actions, public debates about immigration, and changes in policy shape students' mental well-being, sense of safety, and academic performance. By bringing together findings from different sources, this project aims to summarize what is currently known about the relationship between immigration enforcement and immigrant students' educational success and to highlight where more research and support from schools and communities are needed.

Abstract Name: Phenomenology of a Fictional Character

Fictional characters can be seen as something separate from ourselves, a collection of qualities and actions that are simply part of the character as a whole. But our personal experience of fictional characters and the way we interact with them suggests that there is something more: we live through these fictional characters as someone who can move us, shift our orientation towards ourselves, and shape our sense of being. In this paper I will answer what it means to "live as a fictional character" and what our embodied experiences of them look like. Taking inspiration from Maurice Merleau-Ponty's embodied perception, I will be arguing that fictional characters are not just imaginative constructs separate from ourselves, but as someone we inhabit through our experience of reading them. By examining the phenomenological qualities of fictional characters, we can understand how meaning emerges from them and why they matter. Fictional characters are not just someone that we only read about, they are someone that we embody.

Abstract Name: Multi-Epoch Photometry and Spectroscopy of Luminous Blue Variables (LBVs) in the Andromeda (M31) and Triangulum (M33) Galaxies

Mass loss plays a deterministic role in the evolution of high-mass stars ($> 20 M_{\odot}$), especially during the post-main-sequence stages, and luminous blue variables (LBVs) have the highest mass-loss rates of any stars. LBVs, also known as Hubble-Sandage or S Doradus variables, are rare, evolved massive stars that exhibit unpredictable and sometimes dramatic eruptions. Studies of LBVs in the Milky Way reveal that during these outbursts, the ejected mass forms a cool, dense expanded atmosphere or “pseudo-photosphere,” which has been the proposed explanation for the shift in energy distribution from the UV to the visible, resulting in the dramatic brightening in visible wavelengths at constant bolometric luminosity. This is also why LBVs appear to shift from an instability strip during quiescence to a constant-temperature strip at maximum brightness. To further investigate this theory, we have acquired multi-epoch BVRI photometry from the AAVSO and past literature, and used the Multi Mirror Telescope (MMT) Observatory to obtain spectroscopy for several confirmed LBVs and LBV candidates in the Andromeda (M31) and Triangulum (M33) galaxies, which are then used to monitor their change in brightness and color over time. Current results indicate that even though erupting LBVs become reddened as a result of the brightening in optical, this change in color $\Delta B-V$ with respect to the change in brightness ΔMV is insufficient to maintain constant luminosity, which might imply a different physical process governing this enhanced mass outflow. Future implications include obtaining more photometry to cross-check our current observations about their evolution in brightness and color.

Abstract Name: Improvements in Healthspan in *C. elegans* through Cellular Reprogramming

Aging is a natural process of life. With age, however, comes the rise of various chronic diseases. Efforts to develop therapies for humans to combat these diseases have increased in popularity. However, working in humans is extremely complicated and impractical due to potential ethical risks and humans' long lifespan. Alternatively, *Caenorhabditis elegans* (*C. elegans*), a type of worm, has been extensively studied and with their short lifespan, quick reproduction, and high homology (up to 80%) to humans, they serve as valuable model organisms in aging research. Using this non-human model organism, we plan to explore mechanisms that potentially slow or reverse aging clocks, ultimately decelerating the onset of chronic diseases. Specifically, this study aims to determine the extent to which the induction of transcription factors (Yamanaka Factors (YF)) in *C. elegans* improves healthspan, or their quality of life. Prior studies found that recurring activation of YF in mice exhibited significant lifespan extension. However, this has not yet been tested in *C. elegans*. Demonstrating a conserved benefit across many species would support YF activation as a potential therapeutic approach in humans. Thus, the Rothman Lab previously completed an optimization of recurring YF activation in *C. elegans* that maximally extended lifespan. But a long life is meaningless if you are not healthy during this life. Therefore, this study will test the extent of healthspan improvement, given these optimal lifespan extending conditions, specifically measuring thermotolerance, mobility, and oxidative stress

at key life stages. Thermotolerance assays will assess survival to prolonged heat stress. Mobility will be quantified by counting the number of pharyngeal pumps and body bends. Oxidative stress will be measured using H2DCFDA fluorescence staining to measure reactive oxygen species accumulation. Through this work, we hope to determine whether YF activation significantly enhances healthspan alongside lifespan and ultimately strengthen the potential of YF-based therapeutic therapies in humans

Abstract Name: Différance and Meaning in Antiquity and Modernity: The Abjected Versus Objectified Dido in Books 2, 4, and 6 of Virgil's Aeneid

When, in Book 4 of Virgil's Aeneid, Queen Dido transforms from a powerful woman in her own right to a tool used by the gods to forward their own agenda (one which centers a man— Aeneas— and his own apparent destiny), Dido transforms from a figure who is objectified to one who is abjected— that is, someone who is othered and made so repulsive or miserable that they can no longer be looked at directly. Certain ways of writing emphasize the abject in powerful female figures, demonstrating *différance*, or the Derridean concept of how symbols (including components of language, like letters or words) gain meaning. Through a literary analysis of Virgil's Aeneid in its original Latin, in addition to various translations (with special attention paid to Books 2, 4, and 6), I intend to answer the question of to what extent the language of Dido's descriptions within Virgil's Aeneid still retain their old meanings from antiquity, and how this manifests in contemporary depictions, particularly in regards to Dido's power, her body, and perceptions of her (from a Derridean point of view). The writings which will be read and used to frame the character of Dido include Jacques Derrida's *Speech and Phenomena*, *Writing and Difference*, and "Différance," with particular interest in Derrida's writings on abjection and the language of *différance*. The analysis of Books 2, 4, and 6 of the Aeneid will therefore inform how the language used affects perceptions of Dido and her apparent abjection in contemporary understandings/translations. Within its discipline, this research will examine how the Derridean concept of *différance* applies to antiquity, as well as how this affects perceptions and interpretations of powerful women (such as Virgil's Dido) in modernity.

Abstract Name: Design of a Gesture-Controlled Smart Glass Interface Using Computer Vision

Gesture-based interfaces are becoming increasingly important as alternative interaction methods for situations where physical touch is limited or hands-free interaction is preferred. This project explores the design and development of a low-cost, gesture-controlled smart glass system that uses computer vision to allow users to manipulate on-screen elements without touching a device. The goal of this work is to investigate how accessible hardware, such as a Raspberry Pi and a standard webcam, can support real-time hand tracking and create intuitive, touch-free user interfaces. The smart glass system is built by combining a two-way acrylic mirror with a 15.6-inch display panel to create a semi-transparent interactive surface. A camera mounted behind the mirror captures hand movements, and MediaPipe's machine-learning-based hand-tracking model

identifies fingertip positions, detects open- and closed-hand gestures, and calculates motion in real time. These signals are transmitted to a custom interface, allowing users to grab, move, and release digital objects displayed behind the mirror. This creates the appearance of interacting directly with elements “inside” the glass. Expected results include demonstrating stable real-time gesture recognition at practical frame rates, validating that low-cost hardware can support interactive computer vision interfaces, and evaluating how intuitive the gesture mappings feel to first-time users. The project aims to show that embedded systems and open-source AI tools can be combined to create affordable, hands-free interaction technologies with potential applications in accessibility, smart-home interfaces, education, and public information displays. This prototype highlights how computer vision can extend traditional display surfaces into new forms of interactive, gesture-responsive interfaces.

Abstract Name: Just Beyond the Red Circle: Yūsaku Kamekura Rebuilt Post-War Japan Through Design

This paper explores the life and design philosophy of Yūsaku Kamekura, a central graphic design during the post-war period of Japan. He combined traditional Japanese aesthetics with modernist design principles to shape visual elements, highlighting the cultural context and aesthetics of the post-war era. Kamekura conveyed ideas, messages, and emotions through his work to promote cultural modernization and support economic recovery after World War II. Design acted as a social tool, demonstrating the power of visual communication in designs to reach people of Japan and maintain its cultural integrity, which has always been a strategy to unify people during challenging times to improve life during the post-war period through its Olympic Games designs. His collaboration with colleagues not only advanced modern graphic design but also created a platform for effective communication with American foreigners, fostering a positive recovery during the reconstruction period. Kamekura was honored to serve as an inspiration or a model to motivate young designers because many designers and global audiences recognized him for his contributions to post-war Japan.

Abstract Name: Carbon Conscious Concrete: Integrating Pinewood Biochar for Structural Applications

Portland Cement Concrete (PCC) is a composite material composed primarily of Portland cement (PC), coarse and fine aggregates, and water. Its versatility, accessibility, and cost-effectiveness make it the most widely used construction material. However, rising global demand for infrastructure and urban development has intensified concerns over the carbon-intensive nature of PC production, emphasizing the need for sustainable alternatives. Previous research indicates that pinewood biochar, an inherently porous fine material, has potential as a supplementary sustainable cementitious material (SCM) due to its high surface area and carbon sequestration properties. This study investigates the potential replacement of PC with biochar at 2%,

6% and 15% by weight to evaluate its impact on the mechanical performance of PCC while providing environmental benefits. Replacements exceeding 6% of PC were not generally recommended by previous studies, due to considerable reduction in workability and compressive strength of PCC, limiting its suitability for structural applications. Experimental findings of the team confirmed this observation, indicating that high doses of biochar decrease the overall strength of PCC. The 6% biochar mix achieved an average compressive strength of 4.7 ksi and a tensile strength of 439 psi, values consistent with requirements for structural concrete. This study highlights that incorporating biochar can maintain acceptable mechanical properties without adversely affecting curing time or hydration behavior, even across varying water-to-cement ratios in the PCC mix design. The findings demonstrated biochar's promising potential as a SCM in concrete production, contributing to reduced PC usage to support the development of environmentally responsible construction practices.

Abstract Name: Increasing Autobiographical Memory in Individuals Suffering from Dementia through Nostalgia Elicitation from Digital Childhood Photographs

Dementia is a neurodegenerative disease that erodes autobiographical memory and shifts identity, emotional well-being, and interpersonal relationships. As individuals lose access to life experiences, especially from childhood, understanding how memory could be supported becomes crucial in both clinical and everyday settings. This paper investigates how digital photographs from an individual's childhood could act as a form of storytelling, elicit nostalgia, and enhance autobiographical memory in individuals with dementia. Specifically, I explore how the features of digital photography, such as accessibility, organization, and visual quality, affect memory recall and emotional engagement. The central question guiding this research is how digital photographs function as a mediated archive that supports personal memory and identity in the context of dementia. I conducted a comprehensive review of interdisciplinary literature, drawing from neuroscience, psychology, media studies, and dementia care. Studies included EEG and fMRI research on nostalgia's neurological effects, qualitative interviews involving photo-elicited narratives, and experimental findings on nostalgia's psychological benefits. This approach allowed me to examine both the emotional and cognitive dimensions of memory recall through digital imagery. The research suggests that nostalgic digital photographs activate brain regions related to reward, social cognition, and perspective-taking, which may promote self-continuity, social connectedness, and emotional resilience. Further research is needed to understand how the photo helps individuals remember aspects of their lives over time based on the type, emotional connection, and physical reaction the viewers feel. These findings point to a practical and accessible form of memory support for people living with dementia. Incorporating nostalgic digital photographs into therapeutic contexts could foster emotional healing, identity reinforcement, and improved communication with caregivers and loved ones. Future work should focus on developing structured photo-based interventions and testing their efficacy in real-world dementia care environments.

Abstract Name: Multi-Modal Apple Detection - Combining 3D LiDAR and RGB analysis for Precision Orchard Yield Estimation

Fruit yield estimation has been a long-standing challenge, yet few approaches have combined both perceptual (color) and geometric (3D shape) features for single-fruit detection. Earlier methods largely relied on 2D imagery or spectral signatures and modeled apple density across orchards without ground-truth-validated observations—often overlooking the three-dimensional structure of fruit clusters and limiting physical accuracy. We enhance this task by introducing a multi-method pipeline that integrates LiDAR-derived point-cloud geometry and RGB color analysis for robust, ground-truth-verified apple detection and counting. The pipeline combines three complementary components: Excess-Red (ExR) color filtering, RANSAC-based spherical fitting, and DBSCAN clustering to segment apple-like structures while filtering out foliage and background artifacts. A parameter-tuning framework adapts DBSCAN's epsilon, MinSamples, and diameter thresholds across test plots to adjust detection sensitivity for varying canopy densities. To address cases of dense clusters, we explored a K-means refinement step for intra-cluster separation. However, improvements were limited, suggesting that natural fruit clustering and point-cloud sparsity constrain centroid-based refinement. Detection results were georeferenced and evaluated against human-labeled ground-truth datasets to quantify precision and error. Both the spherical-fitting and cubical bounding-box methods achieved approximately 21% relative error and demonstrated strong correlation between estimated and reference counts. We further analyzed performance trade-offs between detection accuracy and computational efficiency, observing stable performance across different orchard conditions. Future work will integrate hyperspectral imagery and adaptive weighting to improve detection under occlusion. Collectively, this study presents one of the first ground-truth-based LiDAR-RGB integrated systems for precise fruit detection, bridging computer vision, remote sensing, and agronomic analysis to support scalable, data-driven orchard management.

Abstract Name: Examining How Facial Expressions Influence Perceptions of Sexual Consent

Affirmative consent emphasizes clear, continuous, and voluntary communication during sexual interactions (Gotell, 2008). Although people often define consent in ways consistent with affirmative consent standards: explicit, revocable, and free of coercion—they frequently communicate it through implicit or ambiguous cues (Jozkowski et al., 2014; Muehlenhard et al., 2016). Such ambiguity complicates both real-time and retrospective assessments of whether consent was granted. Prior research also shows that third-party judgments depend on how closely an encounter aligns with observers' schemas of rape, including expectations that targets physically resist. However, it is unclear whether a target's facial expression influences evaluations of sexual consent, despite the prominence of facial cues in everyday decision-making (Yu et al., 2023). The present study examined whether facial expression shapes perceptions of consensual, nonconsensual, and ambiguous encounters. Eighty-seven female participants completed a 3 (Consent: consensual, nonconsensual, ambiguous) $\times$ 2 (Emotion: happy, neutral) within-subjects design. Participants read 12 vignettes in which a male initiator asked a female target to have sex. The target either clearly agreed, clearly disagreed, or communicated ambiguously; each vignette was paired with a happy or neutral expression. Participants rated perceived consensuality, target sexual desire, and target responsibility. A significant main effect of consent emerged for all variables (p s $\leq$.001). Consensual vignettes were judged as more consensual, more desired, and as placing more responsibility on the target compared with ambiguous

or nonconsensual vignettes. Nonconsensual encounters were rated lowest on these dimensions. Facial expression produced no main effects or interactions ($p > .05$). These findings suggest participants relied primarily on explicit consent cues and clearly distinguished consensual from nonconsensual scenarios. Yet ambiguous communication was not consistently classified as nonconsensual, highlighting a gap between stated definitions of consent and applied judgments. The absence of facial-expression effects indicates evaluators prioritized verbal consent over affective cues.

Abstract Name: Structure–Photophysics Engineering of Small-Molecule Fluorophores for High-Resolution Bioimaging

Fluorescent small molecules are indispensable tools for visualizing biological structures and processes, yet many widely used probes still suffer from poor photostability, low quantum yields, and limited selectivity in complex cellular environments. The central question guiding this project is: How can systematic structural modification of small-molecule fluorophores be used to improve their photophysical performance and biological specificity? Existing research demonstrates that fluorophore behavior is highly sensitive to electronic structure, and that incorporating electron-donating or electron-withdrawing substituents can significantly alter absorption, emission, and stability. However, there remains a gap in understanding how specific substituent patterns influence performance in live-cell environments. This project seeks to address this gap by establishing clear structure–photophysics relationships that can guide the design of next-generation fluorescent probes. To investigate this question, we synthesized a small library of fluorophores with systematically varied donor–acceptor substituents. Each compound was structurally characterized using nuclear magnetic resonance spectroscopy and mass spectrometry, followed by photophysical characterization using UV-visible and fluorescence spectroscopy. These measurements allowed us to evaluate changes in brightness, Stokes shift, and environmental sensitivity. To assess biological compatibility, the probes were tested in live-cell imaging experiments to measure cellular uptake, localization patterns, labeling performance, and cytotoxicity. We expect to identify substituent patterns that reliably enhance photostability, brightness, and selectivity, as well as structural motifs that improve performance in bioorthogonal labeling strategies. The conclusions will focus on the design rules that emerged from this systematic approach and how these rules can accelerate the development of more effective imaging agents for disease diagnostics, targeted imaging, and long-term cellular monitoring.

Abstract Name: Media as a Toxin: Exploring the Detrimental Effects of Korean Drama Viewership on their Audience's Cognition and Resulting Behavior

Following a period marked by extensive immigration and rapid technological development, international films experienced a significant rise in visibility among both domestic and global audiences. By the late twentieth century, Korean dramas—commonly referred to as “K-dramas”—became increasingly prominent with the emergence of the “Korean Wave,” a cultural movement that propelled East Asian media into mainstream popularity. This surge generated a wide range of conflicting interpretations, dividing public opinion between those who view K-dramas as valuable educational tools and those who consider them detrimental forms of media. K-dramas, however, often function as inadvertent sources of malinformation, particularly among impressionable viewers. Many series normalize harmful relationship dynamics while idealizing portrayals of Korean men, potentially encouraging audiences to perceive such behaviors as acceptable or even aspirational. Additionally, these dramas frequently incorporate pervasive alcohol messaging, suggesting that excessive consumption across professional, emotional, and social contexts is both typical and beneficial, despite its real-world risks. They also reinforce narrow and unattainable beauty standards, prompting some viewers to adopt extreme measures in pursuit of these unrealistic ideals. Beyond this, K-dramas can cultivate disproportionate cultural fixations, fostering forms of fandom that verge on obsession and influence behavioral intentions. Although some argue that K-dramas promote mental health awareness, these portrayals are often dramatized and rarely translate effectively into practical, real-world application. Taken together, these factors underscore the need for more critical engagement with K-dramas and greater awareness of their broader social and psychological implications.

Abstract Name: Physics and Calculus of the Sailboat Motion

This research explores the physics and calculus behind sailboat motion, focusing on how a sailboat harnesses wind power to travel, even against the wind. After a brief overview of sailboat evolution and key components (sail, hull, and keel), the study examines how adjusting the sail angle enables efficient upwind motion through vector decomposition of forces. Using Python, the project models the wind as a vector field and applies optimization to determine the most efficient sailing trajectory and the shortest-time path between two points. The results illustrate how principles of calculus and physics intersect to improve understanding and performance of sailboat dynamics.

Abstract Name: Wanna Party with Data? Connecting Richmond Communities with Substance Use Results, Education, and Resources

Rates of substance use overdose in Richmond, VA increased from 44.6 in 2018 to 129.5 per 100,000 city residents in 2023. Our team conducted a series of "community conversations", focus groups, to understand the perceived factors contributing to overdose and resource needs in the community. The aim of this project is to conduct and assess dissemination activities that share research findings identified in the community conversations through community-engaged approaches. In particular, we sought to determine the degree to which inclusion of research results would produce activities that would be positively perceived by community residents and address substance use concerns. Since April 2025, we have implemented two types of community-facing results dissemination activities: (1) "Party with Data" activity tables that share results through trivia-style games and (2) a series of educational workshops, developed in collaboration with non-profit community organizations. Ten "Party with Data" events were conducted between April-November 2025, disseminating results to approximately 300 community residents. At each event, community residents were invited to anonymously share substance use-related topics of interest. Common themes included: engaging in healthy family discussion, support group resources, and strategies to address substance use. Themes from "Party with Data" events, focus groups, and community organization feedback informed the development of day-long community workshops. To date, one community workshop for youth and adults has been conducted (N = 36). Among participants who attended the event, an average of 87.5% agreed/strongly agreed with statements across seven areas (e.g., awareness of available resources, ability to discuss substance use with youth and adults). Inclusion of research results in community events produced activities that improved resource and research awareness and facilitated conversations on substance use. The success of these events encourages future inclusion of research dissemination during community-facing activities.

Abstract Name: Ciliotherapy as a therapeutic approach for fibrotic dermal fibroblasts

Fibrosis can occur in any organ and is characterized by excessive collagen and extracellular matrix production by myofibroblasts, ultimately disrupting tissue structure and function. Although several signaling pathways have been implicated in fibrosis, the underlying molecular mechanisms remain poorly understood. Recent studies have shown that primary cilia (PC) shortening is an early hallmark that drives the fibrotic reprogramming of dermal fibroblasts. Moreover, Spag17 and other cilia-associated genes play a critical role in regulating primary cilia length and, consequently, fibrotic responses. Loss of Spag17 function leads to cilia shortening, spontaneous myofibroblast transition, and activation of profibrotic pathways, including TGF- β signaling, resulting in increased collagen deposition and fibrosis. Therefore, we hypothesize that therapeutic modulation of PC length (termed ciliotherapy) represents a promising strategy for preventing or even reversing fibrosis. To evaluate this therapeutic approach, we treated Spag17 KO fibroblasts with LiCl and forskolin—two compounds known to modulate cilia length—as well as with a PDE4D inhibitor, a modulator of phosphodiesterase activity involved in cilio genesis. We then assessed treatment effects by immunofluorescence analysis of profibrotic markers. All treatments effectively restored PC length in Spag17 KO fibroblasts and reversed the fibrotic phenotype, as evidenced by reduced expression of the myofibroblast marker α -smooth muscle actin (ASMA) and procollagen, along with a lower nuclear-to-cytoplasmic ratio of

SMAD2/3, indicating deactivation of TGF- β signaling. In conclusion, these findings highlight the therapeutic potential of targeting primary cilia-related mechanisms to reverse fibrosis.

Abstract Name: The Promise of Artificial Intelligence in Anesthesiology: Rapid Review

Artificial intelligence (AI) is increasingly applied in modern healthcare, including anesthesiology. Numerous AI applications have been developed in this field. However, their use in clinical practice remains uncertain. This study aimed to provide a clear overview of the current state of AI integration in anesthesiology, with a particular focus on the positive impacts of AI within anesthetic practice. A rapid review was conducted following the 2020 Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. We searched MEDLINE via PUBMED for articles published from 2015 to November 2025 using terms related to AI, application, and anesthesiology. Articles that were secondary/ tertiary articles, non-English, or involved animal subjects were excluded. The accuracy and risk of bias of each study were assessed using the Cochrane Risk of Bias Tool. A total of 47 studies were included. Regarding their clinical applicability, we found that the studies fall into 5 groups: (1) Monitor/Control depth of anesthesia, (2) Event and risk prediction, (3) Pain management, (4) Ultrasound guidance, and (5) Miscellaneous. Event and risk prediction represented the largest category (32/47 studies). Although limited by a single database search, this review found that AI showed considerable promise in anesthesiology for enhancing patient safety, supporting clinical decision-making, and improving workflow efficiency. Further research is needed to validate these technologies across diverse patient populations and clinical settings, and to establish guidelines for safe implementation.

Abstract Name: Investigation of the Localization of Fucoxanthin and Fucoxanthinol in BEAS-2B Cells

Fucoxanthin is a carotenoid that naturally occurs in microalgae. Fucoxanthin and its active form, fucoxanthinol, have shown potential in reducing anti-inflammatory reactions in the human body, specifically in respiratory diseases. However, their specific biochemical or cellular processes are unknown. To address the cellular processes, we will determine the subcellular localization of these compounds in respiratory cells. Namely, the compounds will be tested at different concentrations on BEAS-2B cells, a line of human bronchial epithelial cells. The application of these compounds on the cells will then be analyzed by spectroscopic and microscopic methods, such as fluorescence microscopy and Raman spectroscopy. Through these methods, the localization of the compounds in these cells will be investigated. It is expected that

fucoxanthin and fucoxanthinol will inhibit inflammatory responses through interactions with interleukin signaling in the cells. Furthermore, we expect fucoxanthinol to have a more effective inhibition of inflammatory responses in the cells compared to fucoxanthin as it is the active metabolite of fucoxanthin. The findings of this research can contribute to major advancements in pharmaceuticals for respiratory diseases. This research also promotes the use of marine-derived bioactive compounds, reducing dependence on synthetic alternatives, and ultimately supporting sustainable production processes.

Abstract Name: Spray-Dried Lung Extracellular Matrix Microparticles for Acute Respiratory Distress Syndrome-Related Bacterial Infections

Acute respiratory distress syndrome (ARDS) is a severe form of lung injury with a high mortality rate and no cure. ARDS is characterized by pulmonary edema, gap formation in endothelial tissue, an influx of inflammatory cells, surfactant dysfunction, a decrease in lung compliance, and hypoxemia. One of the leading causes of ARDS is bacterial lung infections, with community-acquired pneumonia (CAP) and ventilator-associated pneumonia (VAP) being the most common forms. Patients with ARDS who receive mechanical ventilation are at a much higher risk of developing VAP, with the most common pathogens belonging to the ESKAPE group. Rising rates of antibiotic resistance among these pathogens and the lack of targeted treatments for ARDS emphasize the need for novel therapies and drug delivery carriers that not only prevent lung infection but also address the pathologic immune response and attempt to reverse structural changes in injured lung tissue. This study aims to develop extracellular matrix microparticles (ECM MPs) that have bacteriostatic, pro-regenerative, and anti-inflammatory properties when tested in bacterial and in vivo models of ARDS. Decellularized pig lung ECM was combined with excipients like DPPC and L-leucine to mimic lung surfactants and enhance the dispersibility of delivered aerosols while minimizing mouth-throat deposition loss. This novel formulation was then spray dried to yield particles with diameters in the range of 1-5 μm , with an average size of 1.2 μm , and a composition of 10% ECM, 25% L-Leucine, and 65% DPPC. To evaluate and optimize the efficacy of this formulation, bacterial inhibition assays are currently being conducted, and effective antibacterial activity is expected to produce a dose-dependent decrease in OD600 relative to untreated controls. Preliminary data indicate that the current ECM MP formulation is effective in reducing growth of E.coli. Ongoing studies will determine the consistency of this effect across varying concentrations and bacterial strains.

Abstract Name: Sexual Health Education, Attitudes, Experiences, and STI Testing Rates of College Students

at the University of Central Oklahoma

Sexually transmitted infections (STIs) are a significant public health problem that can cause serious long-term health consequences if left untreated. The reduction of incidence, transmission, and complications associated with STIs requires prompt testing, diagnosis, and treatment. College students in the United States face a disproportionately high risk for STIs. They are more likely to engage in risky sexual behavior, less likely to utilize STI testing services, and face more barriers to sexual health. Previous research has indicated a lack of sexual health knowledge and attitudes towards sexual health influences the likelihood of engaging in risky sexual behavior. This study sought to assess the sexual health of college students at the University of Central Oklahoma and how it is impacted by their previous sexual education and structural barriers to healthy sexual behaviors. A cross-sectional, mixed-method online survey was conducted over the spring semester of 2026, recruiting university students from the University of Central Oklahoma via an all-student email. The anonymous questionnaire assessed student demographics, sexual education history, STI testing behaviours, sexual risk behaviours, knowledge, and five psychological constructs indicated to be predictive of STI testing from previous research: attitudes, perceived susceptibility to STIs, social norms, social fear and self-efficacy. The possible responses to questions related to sexual health were graded on a point scale, with a higher point value indicating alignment with practices that promote or improve sexual health. Optional follow-up interviews provided in-depth information regarding attitudes about sexual health and sexual health education. The survey responses will be compared to STI infection data provided by the Oklahoma State Department of Health. Efforts to improve sexual health on college campuses and provide evidence-based sexual health education will benefit from the data collected by identifying public health priorities and tailoring health promotion strategies to the needs of UCO students.

Abstract Name: Utilizing Plant-Pollinator-Microbe Networks to Explore a Novel Method of Pathogen Tracking via CRISPR-Cas9 Engineered *E. coli* and *S. cerevisiae*

The interaction of pollinators like bees with the flowers in a plant-pollinator network is a key component of microbial spread through ecosystems, with flowers acting as hubs of pathogen transmission. Microbes can travel on or inside of pollen grains, live on the surfaces of plants, and reside within the flower's nectar. The interaction of bees and flowers is a reciprocal transmission route for microbes that shapes their respective microbiomes. The primary purpose of this research is to develop a novel method of tracking pathogens in non-sterile environments by synthesizing a genetically distinct DNA barcode sequence that is inserted into the genomic DNA of *Escherichia coli* K-12 and *Saccharomyces cerevisiae* using CRISPR-Cas9. Doing so will also allow for the development of a methodology for tracking the movements of pathogens within plant-pollinator networks to support further research into their microbiomes. A genetically distinct DNA sequence, or barcode, was synthesized for insertion in the nuclear genomes of non-pathogenic *E. coli* K-12 and *S. cerevisiae* using the *Streptococcus pyogenes* type II CRISPR-Cas9 system. The barcode sequence was inserted into the internal transcribed spacer (ITS) region between the small- and large-subunit rRNA genes of the genomic DNA of both model organisms. The successfully transformed bacteria and yeast colonies were lyophilized, producing an inert powder. The lyophilized cells were applied to flowers in a pollinator garden, where they were collected by visiting bees and carried back to their hive. The hive was outfitted with a trap that collects the debris deposited by the bees. The debris was regularly collected and analyzed using qPCR and DNA sequencing. Data analysis is being conducted to determine the method's success. The ability to track the spread of pathogens in non-sterile environments such as the plant-pollinator network is of concern as climate change changes the landscape of plant-pollinator networks and their pathogen transmission.

Abstract Name: Improving Zinc Oxide Nanorod Synthesis for Enhanced Electrochemical Sensor Performance

Zinc oxide (ZnO) is a biocompatible inorganic semiconductor with a wide bandgap and high electron mobility, making it suitable for light emitting, catalytic, and sensing applications. This study focuses on optimizing the hydrothermal synthesis of ZnO nanorods by examining the effects of autoclave temperature and surfactant choice on crystallinity, diameter, and aspect ratio. Optimal growth conditions were identified at 150°C with the precursor solution containing a one to one ratio of sodium dodecylbenzenesulfonate and sodium hydroxide. These conditions produced nanorods with an average diameter of 50 nm and high length-to-diameter ratios, which provide a large surface area that supports improved sensor performance. X-ray diffraction confirmed the wurtzite crystal structure of the ZnO, and scanning and transmission electron microscopy characterized nanorod morphology. UV visible spectroscopy showed a strong absorption peak at 370 nm, corresponding to an estimated 3.35 eV bandgap which is consistent with high quality ZnO. The nanorods were then applied as a thin layer to the electrode in the electrochemical sensor and evaluated using cyclic voltammetry. During measurement, the electrolyte solution undergoes a redox reaction that generates current. In this process, the analyte, which is the chemical species in the solution that gains or loses electrons, diffuses to the electrode surface. When the redox reaction occurs, electrons move through the ZnO layer to the sensor, demonstrating that ZnO can conduct charge and has useful electrical properties for sensing. Future work will refine ZnO integration with electrode materials, explore alternative synthesis routes, and assess the performance of ZnO modification in biosensing and photoelectric applications. This research contributes to the development of sensitive, accurate, and scalable ZnO based sensors for environmental, biomedical, and industrial use.

Abstract Name: Electrical Capacitance to High-Observation resolution (ECHO) as a Solution to Mass-Gauging of Cryogenic Fuel in Microgravity for Spaceflight Applications

As the space industry prepares to embark on extended missions to the Moon and Mars, it has become evident that current mass gauging techniques are not sufficient for long duration space travel. Current techniques often rely on bookkeeping, calculations using pressure readings, or measurements utilizing intermittent accelerations burns to measure propellant usage. Such methods are unreliable due to estimation errors, propellant sloshing, and propellant boiloff, all issues which are aggravated during long duration missions. This paper proposes a novel solution called Electrical Capacitance to High resolution Observation (ECHO), which adapts Electrical Capacitance Tomography (ECT) as well as implements a machine learning (ML) algorithm to accurately and continuously measure propellant quantities. When implemented, ECHO will line the interior of a spacecraft propellant tank with rings of capacitance measuring electrodes. Each electrode pair can gather its own unique capacitance measurement. Higher concentrations of mass between a given electrode pair will produce a higher capacitance measurement, and as such, higher capacitance values represent a higher concentration of mass across any given exciting-measuring electrode pair. This data is then read by the ML algorithm which, by recognizing patterns in the measurements, generates accurate cross-sectional images and mass estimates of the interior of the tank, with significant computational reductions versus current reconstruction methods. To prove functionality of the system, the current testing setup is composed of a cryogenic dewar whose interior is lined with electrodes printed on a flexible PCB. Current ECHO tests are being on 3D-printed cross-sections, and in the future, ECHO will be tested with liquid nitrogen to confirm operation in extreme temperatures. With funding from Embry-Riddle Aeronautical University and NASA's Human Lander Challenge, ECHO will be tested with on-ground cryogenic fluid and a parabolic, sub-orbital flight test for the preparation of eventual space applications.

Abstract Name: Mental stress, physical activity and reproductive health: a pilot study on college-aged females in STEM

Undergraduate students enrolled in STEM (Science, Technology, Engineering and Mathematics) programs face rigorous academic demands that place them under immense stress. Chronic exposure to stress elevates cortisol, a key hormone known to disrupt endocrine function, including the reproductive system; such disruptions may contribute to menstrual irregularities. Among mediators that help the body return to homeostasis, physical activity is widely recognized as an effective tool for managing stress. Although previous literature has documented the relationship between stress and reproductive health, as well as the benefits of physical activity for stress relief, limited research has examined how physical activity may buffer stress related reproductive disruptions within the undergraduate STEM student population. The central research question guiding this study is whether physical activity mediates the relationship between academic stress and reproductive health among college-aged females in STEM programs. The purpose of this study is to evaluate the potential mitigating effect of physical activity on stress induced physiological changes. To investigate this question, researchers recruited eight female STEM students from the University of Dayton. Participants attended three data collection sessions scheduled before, during and after midterms to capture changes across a period of academic stress. At each session, participants provided passive drool saliva samples for cortisol measurement and completed five questionnaires assessing general health, reproductive status, stress levels and physical activity engagement. The same procedures were followed at each session. It is expected that participants with higher physical activity levels will exhibit lower cortisol reactivity during peak academic stress and report fewer disruptions to reproductive status. Findings will be discussed in the context of improving stress management strategies for undergraduate women in STEM, with attention to implications for reproductive health, academic performance and overall wellbeing. This study seeks to contribute new insight to an understudied intersection of stress, physical activity and reproductive health.

Abstract Name: Exploring soil remediation and its significance for site development

As part of an independent undergraduate research project, I collaborated with the University of Kentucky's Department of Plant and Soil Sciences to assess soil toxicity across brownfield sites in Lexington's Distillery District and to examine how contamination influences public health and environmental quality. This scientific investigation directly informed my final architectural studio project, where I designed a proposed soil remediation facility that combined industrial treatment processes with public engagement. I selected three sampling zones: a disturbed site near railroad tracks, a reclaimed section of the Legacy Town Branch Trail, and an agricultural grassland control. These locations represented different levels of human impact and allowed for interesting comparison. Working with soil science researchers, I analyzed pH, macronutrients such as phosphorus and potassium, secondary nutrients including calcium and magnesium, and heavy metals including lead, cadmium, and zinc. Elevated pH and calcium levels suggested the influence of limestone dust from quarry activity, while heavy metal concentrations indicated legacy industrial pollution. These findings clarified how hidden chemical conditions shape both environmental health and the potential of contaminated sites. By integrating the scientific results into my design work, I explored remediation strategies such as phytoremediation gardens, constructed wetlands, and community soil laboratories. In the speculative facility, these strategies were developed not only as ecological interventions but also as public amenities that help make environmental processes visible and accessible. This project demonstrates how laboratory analysis can guide architectural decision-making and how remediation can become an opportunity for education, restoration, and community involvement.

Abstract Name: Antimicrobial Stewardship: Identifying Communication and Procedural Gaps Between the Medical Laboratory and the Clinician

In October of 2025, the World Health Organization warned the medical community that one in six bacterial infections worldwide are now resistant to antimicrobial treatments. Drug-resistant bacteria are just one specific type of antimicrobial resistance. The inclusion of fungi, viruses, and parasites that no longer respond to antimicrobial drugs are a global threat to public health. This current global concern requires enhanced antimicrobial stewardship. Antimicrobial stewardship can impact the growing phenomenon of antimicrobial resistance. However, its success greatly depends on the effective collaboration between the medical laboratory and the ordering clinician. Antimicrobial stewardship has been hindered by a lack of communication, training, incompatible scheduling, and technological difficulties between the medical laboratory and clinicians resulting in compromised patient care. Key strategies that focus on better management and control of the factors responsible for these communication and procedural issues must be determined and implemented. This review's thorough analysis of the literature identifies multiple recommendations that provide medical laboratory scientists (MLS) and clinicians with effective methods to bridge operational, procedural, and communication gaps. The aim of this literature review is to provide solutions that will serve to improve communication and reporting guidelines, MLS-clinician interactions, and patient specimen retrieval protocols to strengthen existing antimicrobial stewardship programs.

Abstract Name: Impact of Early Life Stress on Blood–Brain Barrier Gene Expression following Skeletal Fracture in Mice

Exposure to stress early in life increases the risk of adverse health outcomes later in life. A common challenge faced by the general population is a skeletal fracture requiring surgical repair, yet the impact of early life stress on fracture outcomes is poorly understood. Previous rodent studies have demonstrated that early adversity can sensitize neuroimmune and vascular systems so that later stressors produce an exaggerated or altered inflammatory response. In fact, two-hit studies have illustrated that a peripheral immune challenge and a history of psychological stress together, but not alone, can synergistically amplify brain immune responses, raising the question of whether the blood–brain barrier responds differentially to peripheral challenges in those with a history of early life stress. The current study tests the hypothesis that a history of early life stress will alter the blood–brain barrier response to a peripheral skeletal fracture. This study uses a two-hit mouse model in which early life predator stress is followed by an adult orthopedic surgery or sham procedure to test whether stress history alters late blood–brain barrier recovery in the prefrontal cortex. Male and female mice are assigned to early life predator stress or no predator stress, and later receive a bone fracture under anesthesia and analgesia or a sham surgery, yielding a 2 by 2 by 2 design. Prefrontal cortex tissue was collected 7, 14, or 28 days after surgery and compared to tissue from control mice. Gene expression of the primary tight junction gene occludin (Ocln) will be quantified by RT-qPCR to determine whether early life stress and adult fracture surgery are associated with persistent alterations in a marker of blood–brain barrier integrity. Understanding the impact of early life stress on recovery from skeletal fractures will provide foundational knowledge to support future comprehensive personalized medical care.

Abstract Name: The Effects of Aerobic Fitness on Bilateral Transfer in Older Adults

INTRODUCTION: Transfer between limbs in older adults is typically symmetrical, with similar changes in the non-dominant limb following practice with the dominant limb and vice versa. This symmetry is caused by compensatory hemispheric activation due to motor control deficiencies with aging. Higher aerobic fitness has been shown to help older adults retain healthy hemispheric activation. Previous research shows that high reported physical activity exhibits asymmetrical transfer in older adults similarly of young adults. The purpose of this study was to examine the effects of aerobic fitness on bilateral transfer in older adults.

METHODS: 12 right-handed participants (65-80) were grouped by aerobic fitness level determined via a 2-minute walk test to estimate VO2 max following training. Prior to training, handedness was determined via the Edinburgh Handedness Inventory. Individuals performed a 30° visual rotation drawing task assessing movement parameters. Pre-test of two trials with each limb established baseline performance, followed by 40 practice trials on the left limb. Post-tests mirrored pre-tests assessing same-side learning and the transfer of motor planning parameters including movement time, normalized jerk, trajectory length, and initial direction error. **RESULTS:** A 2 (time) x 2 (group) repeated measures ANOVA was conducted for each independent variable. A main effect for time showed bilateral transfer occurred irrespective of aerobic fitness for movement time (Meandiff = 1.24s ± .226; F(3,8) = 21.9, p<.001) and normalized jerk (Meandiff = 5862.23 ± 1310.7; F(3,8) = 16.6, p<.001). However, transfer did not occur for trajectory length (Meandiff = .182cm ± .065; F(3,8) = 10.04, p>.05) or initial direction error (Meandiff = .005° ± .003; F(3,8) = 17.2, p>.05). **CONCLUSIONS:** Our findings suggest that older adults exhibit younger adult hemispheric activation, and certain motor parameters are not influenced by aerobic fitness. These findings could be due to compensatory hemispheric activation being motor parameter specific.

Abstract Name: Development of an AI model for detecting fluorescence intensity in cell lines & the cells of vestibular system

More than 35% of US adults aged 40 years and older (~69 million Americans) have had a vestibular dysfunction at some point in their lives. Vestibular disorders may be caused by disease, injury, drug or chemical poisoning, or aging. Symptoms of vestibular disorders include dizziness, vertigo (a spinning sensation), imbalance, fatigue, jumping vision, and cognitive difficulties. There is no “cure” for most vestibular disorders; however, they can be managed with medication, physical therapy, lifestyle changes (e.g., diet, exercise), or surgery. In most cases, patients must adapt to a host of life-altering limitations. In the US, medical care for patients with chronic balance disorders exceeds \$20 billion per year. The AI model we intend to develop is a hybrid approach that integrates convolutional neural networks (CNN) with vision transformers (ViT) to quantify fluorescence intensity. The proposed hybrid approach can simultaneously capture local fluorescence patterns with CNNs and global contextual understanding with ViT. Unlike per-cell analysis pipelines that crop and analyze cells independently, this architecture accounts for spatial relationships between neighboring cells, enabling robust quantification of fluorescence intensity. Our AI model’s fluorescence intensity detection will be compared with ground-truth values using the Pearson correlation coefficient, mean absolute error, and Bland–Altman analysis. Determining the fluorescence intensity in cell lines will be the first step in establishing the role of LRP2 in cellular transport of aminoglycosides. These initial data will be used to secure grants and other resources to determine the role of LRP2 in zebrafish and mouse explants.

Abstract Name: Credibility and Misinformation in American College Students.

Currently, there seem to be no meaningful regulations on online news. People posing as doctors sell “miracle supplements,” commentators pretending to be political experts use the same set of facts to portray individuals in entirely different lights, and websites masquerading as official news sources publish stories that may be wholly false. And yet, all of this is protected by the First Amendment. Free speech is the first requirement of a free democracy, and regulations must not be enacted that would infringe on this essential right. Such controls allow those in power to shape the perception of their citizens, and even well-intentioned limitations can be weaponized into a form of authoritarian influence. However, the alternative—a system with no oversight or accountability—produces its own dangers. The unfiltered freedom of modern media can reinforce misconceptions, amplify confirmation bias, and lend legitimacy to unfounded science. Where complete governmental control leads to tyranny, total absence of regulation invites informational anarchy. Both extremes ultimately threaten the survival of free society. Since government regulation is unacceptable and market forces have failed to promote truth over engagement, the responsibility falls on individual consumers. Everyone must learn to critically assess the information they receive. To do this, we must first understand how we think about information itself, and in particular, how we evaluate the credibility of a source. This study seeks to understand the link between source credibility and belief through a long-reaching poll of American college students that uses a variety of similar texts to evaluate whether the salience and perceived credibility of a source drastically influence how much a single text influences a belief. It is expected that low salience will cause the credibility of a source to have a lower impact on the perceptions of a reader, and high salience will have the opposite effect.

Abstract Name: The Art of Connection: Creative Healing After Stroke

Stroke is the fifth leading cause of death in the United States and a major source of long-term disability. Reduced social engagement, emotional distress, and a lack of possibilities for community involvement are common among survivors, all of which hinder recovery. Research indicates that peer support, community programs, and arts-based activities can improve psychosocial well-being, cognitive resilience, and social connectedness. Guided by this evidence, The Art of Connection: Creative Healing After Stroke was developed as a six-week community art program aimed at enhancing social participation, emotional expression, and fine motor involvement in adult stroke survivors. Sessions were held at a local accessible church and facilitated by rehabilitation science students. Activities included painting, jewelry making, clay sculpting, picture-frame decorating, a collaborative mural, and reflective art naming. The program used a service-learning approach that benefited both students and participants. To measure perceived social connectivity and engagement, the Stroke Impact Scale (Participation Domain) and the Friendship Scale were administered at baseline and the final session. Results showed an increase in social participation, with SIS scores rising from $M = 63.54$ to $M = 78.13$ ($+14.58$). Although not statistically significant (Wilcoxon $Z = -1.633$, $p = .102$), all participants improved. Friendship Scale scores remained stable (Pre: $M = 6.33$, Post: $M = 5.67$; $Z = -.447$, $p = .655$), suggesting a constant sense of social contact throughout our brief program. Additionally, higher mood, collaboration, shared story, and increased involvement were seen in qualitative assessments. By combining a supportive group environment with creative expression is an example of the advantages of attending to psychological needs of stroke survivors. Partnerships with academic programs,

places of worship, and rehabilitation organizations encourage sustainability and ongoing art classes. The Art of Connection shows how accessible, low-cost arts programming can strengthen social connectedness and enhance community-based stroke recovery.

Abstract Name: Study of Gene Expression for FLOWERING LOCUS T and SEPALLATA 2-like Genes in *Solanum tuberosum*

In *Solanum tuberosum* (potatoes), flowering serves as a visual indicator that tubers have begun to develop underground. FLOWERING LOCUS T (StFT) proteins are known to act as mobile signals to initiate flowering. While researching more homologous genes with similar functions, a SEPALLATA 2-like gene (StSEP2) was identified in the potato genomic databases but was discovered to be mostly uncharacterized. This study aims to determine the location and quantity of expression for StFT and StSEP2 across different developmental stages in Caribou potatoes. Tissue samples were taken from both reproductive (buds, sepals, petals, stamens, ovaries, pedicles, fruits) and vegetative tissues (roots, stems, stolons, leaves, meristems) of the plant across five major stages of development: pre-planting, bud formation, flowering, post-flowering, and fruiting (which was a fruit-only sampling). Additionally, floral bud samples were collected from ten distinct size-based developmental stages. All samples will undergo RNA extraction and be analyzed using quantitative PCR (qPCR) analysis to assess gene expression levels across all tissues and timepoints. The goal is to generate a timeline of StFT and StSEP2 expressions to provide insight into their roles in both reproductive signaling and floral organ development.

Abstract Name: Tardigrade Bio-Exploration Reproduction Research Payload

Tardigrades, affectionately known as “water bears”, are a well-known scientific peculiarity studied for their tolerances of various extreme environments. The Tardigrade Bio-Exploration Reproduction Research Payload (tBEARR) is an external International Space Station (ISS) payload module under development by the Embry-Riddle Orbital Research Association (ERORA), an undergraduate research club at Embry-Riddle Aeronautical University in Daytona Beach, FL. The project is an undergraduate student-lead project researching the ability of *Hypsibius exemplaris* to reproduce in Low Earth Orbit while exposed to space radiation. The metabolically active cultures will be housed in an undergraduate student-built module to be attached externally to the ISS and exposed to radiation. The Payload Team has a focus on building the external payload module, designing and operating life support systems, and remotely collecting data from the onboard systems. The Research Team’s primary purpose is to conduct on-ground experiments to provide an

experimental control dataset. In preparation of the mission, the Research Team is currently researching and with on-ground experiments, quantifying the severity of specific stressors that tardigrades can tolerate in order to guide the Payload Team's systems requirements. These stressors include thermal stress, anoxia, and microgravity. While previous missions showed that tardigrades can survive brief exposure to Low Earth Orbit, there is a knowledge gap as to whether they can successfully reproduce under sustained radiation and environmental stress. The project's overall mission statement is to investigate the consequences of prolonged exposure on reproduction during spaceflight, providing insight into the possibility of reproduction in space for more complex organisms.

Abstract Name: The Storytelling Project: Building Belonging Through Narrative

This presentation examines my experience designing and implementing a student-led creative journal for Texas Woman's University's Department of Language, Culture, & Gender Studies. Many institutions provide opportunities for students to participate in publications as contributors and managers; few, however, offer the chance to build a journal from the ground up. Yet doing so expands how programs allow students to apply the literary, rhetorical, and linguistic skills they gain. In addition to developing submission and editorial workflows, I will establish processes to support a multilingual mission that fosters inclusiveness and provides readers exposure to other languages and cultures. In my research, I hope to answer several questions. What does it take to start a student journal, and what are the benefits to English majors leading this process? What does a student staff look like, and what will the workflows be? How will we address rubrics and submission guidelines, as well as the peer-review process? I plan to reach out to other institutions with student-led journals to better understand their models, which will aid in developing mine. In turn, I aim to establish a network beneficial to all parties, including those seeking to launch similar efforts on their own campuses. Through this exploration, I aim to demonstrate the value of inviting students to participate not only in publication processes (as contributors or editors) but more significantly as primary developers of the journal's design and infrastructure. I will also offer suggestions for maintaining student engagement post-launch, as the goal is to ensure the journal continues contributing to student success for years to come.

Abstract Name: The impact of Fed Rate Announcements in Shaping Returns in High-Growth Tech vs. Traditional Rate-Sensitive Sectors

This project analyzes how different sectors of the U.S. economy respond to Federal Reserve interest rate announcements, focusing on high-growth technology firms and traditional rate-sensitive industries. Although these sectors are often grouped together as being sensitive to monetary policy, they react through distinct economic mechanisms. Traditional sectors tend to respond to interest rate changes through shifts in borrowing costs, mortgage rates, and credit-market conditions. High-growth technology firms, however, derive a significant portion of their valuation from expected future earnings, which makes them behave like

long-duration assets and more sensitive to changes in interest rate expectations rather than the direct cost of borrowing. To evaluate these differences, the study uses an event-study method centered on the Federal Open Market Committee (FOMC) announcement dates from 2010 to 2024. Stock returns, trading volume, and volatility are measured in short windows surrounding each announcement, with a distinction made between expected policy decisions and policy surprises. Abnormal returns are calculated for each sector to isolate the market's reaction specifically attributable to monetary policy communication. Preliminary research shows that high-growth technology stocks exhibit faster and more distinct price movements in response to Federal Reserve announcements, especially when the decision deviates from market expectations. Traditional sectors tend to react in steadier and less dramatic ways. Their movements follow the typical economic effects of changing interest rates, such as shifts in loan demand or investors moving toward or away from safer industries. These patterns suggest evolving differences in how investors interpret monetary policy across sectors, as well as increasing sensitivity within the technology sector over time. By comparing sector-level responses across more than a decade of policy announcements, this project provides insight into how monetary policy shapes modern financial markets while highlighting the importance of understanding sector-specific channels of rate sensitivity.

Abstract Name: Effectiveness of 3-Dimensional Airfoil-shaped Collars On Reducing Pier Scour

Bridge pier scour is when the obstruction and diversion of regular flow leads to the removal of sediment surrounding bridge pier structures. Scour is unpredictable and difficult to detect, making it extremely dangerous as uneven scour causes differential settlement, tilting, and ultimately, collapse. Recent studies on airfoil shaped geometries for piles have shown success in reducing the effects of scour. In 2023, the National Institute of Technology Waranga demonstrated that airfoil shaped pier collars with optimized dimensions reduced scour by 100%. When placed at bed level, the collars directly combated scouring by blocking the impact of horseshoe vortices. Likewise, in 2019, the Indian Academy of Sciences conducted experiments with extruded airfoil shaped piers tested the effects of the orientation of the airfoil on scour depth. When the extruded airfoil-shaped pier was oriented with the tail facing upstream, the formation of wake vortices was reduced by streamlining the diversion of flow. While effective, neither of the two aforementioned solutions combat both horseshoe and wake vortices. Thus, the 3D airfoil shaped pier collar (ASPC) is proposed as a combination of the flat collar and vertical extrusion concepts. By combatting both types of vortices, ASPCs with smaller footprints were tested to compare scour reduction versus individual flat collars and vertical extrusions. Model 3D printed ASPCs with varying diameter-to-width and diameter-to-tail length ratios were placed in a flume with a sand sediment bed to test if they achieved similar results to collars and extrusions within a smaller footprint. Under steady flow conditions, the scour depth after 6 hours was measured for each variation and compared to the control pier which had no collar. In practice, successful ASPCs would provide scour protection while requiring less material and construction effort.

Abstract Name: Implementation of a School Health Report Card to Improve Health Outcomes in a Low-Resource Elementary School

The Creighton University College of Nursing (CUCON) Health Promotion program has provided annual state-mandated health screenings for children in six low-resource parochial schools since 2004. These schools serve racially and ethnically diverse students who experience high levels of socioeconomic disadvantage, placing them at increased risk for adverse health and academic outcomes. Although routine screening identifies concerns related to body mass index (BMI), blood pressure (BP), vision, hearing, and dental health, there is currently no systematic method to ensure follow-up after abnormal findings. Challenges include inconsistent calculation of BMI and BP percentiles and the absence of a structured process to support communication with parents or track follow-up care. To address these gaps, this quality improvement (QI) project aims to implement a School Health Report Card (SHRC) to improve health outcomes in one partner school. This pilot project involves developing a reliable pediatric BMI and BP calculator and a secure, locally run web-based application to facilitate accurate data entry and automated SHRC generation. Individualized SHRCs will provide screening results, interpretations, and low-cost or no-cost referral resources. Parents/caregivers will receive a follow-up survey one month after SHRC distribution to evaluate completion of recommended care and satisfaction with the SHRC. Existing program data will serve as baseline measures to assess changes in referral patterns, follow-up completion, and parental perceptions of the tool's usefulness. Outcomes will determine whether the SHRC improves communication, increases follow-up for abnormal screenings, and enhances parental engagement in child health. Anticipated benefits include earlier intervention, improved health and academic performance, and strengthened partnerships between families and school health providers. If effective, the SHRC model may be expanded to additional schools served by the CUCON Health Promotion program.

Abstract Name: Genomic Analysis of Cold-Adapted *Sulfitobacter pontiacus* from Antarctica

The Antarctic region is described as a frigid, oligotrophic environment. During a November 2009 expedition, phytoplankton were observed in the bottom 5 cm of the sea ice cores collected from Ross Sea, McMurdo Sound Station, Antarctica. This study focuses on understanding which type of heterotrophic bacteria are associated with these algae/phytoplankton and whether they have the genomic capacity to utilize these carbon sources. To test this, we used an enrichment culture approach using laminarin and cellobiose as the sole carbon source. The resulting microbial growth was serially diluted and plated on seawater-complete media (SWC), from which four well-isolated colonies (01DW25, 04NG25, 01KJ25, and 01JM25) were selected for pure culture. The 16S rRNA gene was amplified and sequenced. The phylogenomic analysis identified these isolates as *Sulfitobacter pontiacus*. Growth rate estimates on SWC and defined media showed that these isolates did not utilize beta-glucan, suggesting that other microbes had broken down algal polysaccharides into oligo- and monosaccharides (public goods) before isolation. Whole-genome shotgun sequencing and comparative genomic analysis with ANVIO confirmed that the Average Nucleotide Identity (ANI) between

the *S. pontiacus* isolates and their closest relative, *S. pontiacus* (GCF_022788675.1), is 97.9%. CAZyme screening showed 22 glycoside hydrolase genes and 37 glycosyl transferase genes. These findings suggest that these psychrotrophic strains have the capacity to break down complex carbohydrates and adopted an energy-conserving strategy called carbon catabolite repression in the lab, which implies that these isolates represent a cheating strain of *S. pontiacus* that likely uses cross-feeding to sustain itself within Antarctic microbial communities, given the inherent costs of resource acquisition in a cold, oligotrophic environment. Future proteomic analyses will investigate specific proteins involved in carbon utilization and environmental responsiveness.

Abstract Name: Lightweight Intrusion Detection for IoT: Deploying Machine Learning on Resource-Constrained Edge Devices

The expansion of Internet of Things (IoT) devices and edge computing has increased the vulnerability of modern networks to cyberattacks. Traditional signature-based intrusion detection systems (IDS) cannot reliably identify new or rapidly evolving threats, and many machine learning-based IDS solutions are too computationally expensive for small edge devices. This project investigates a lightweight, anomaly-based IDS designed specifically for resource-constrained hardware such as the Raspberry Pi 3B+. Using the TON-IoT and CICIDS2017 datasets, we trained multiple machine learning models, including multilayer perceptrons, 1-D convolutional neural networks, and random forests, and achieved offline accuracies exceeding 95%. These models were then deployed onto the Raspberry Pi to evaluate their real-time performance in simulated edge environments. Early experiments, including port-scanning detection tests, show promising accuracy levels (88%), demonstrating the potential of these compact models to operate effectively under strict hardware limitations. Our findings highlight a practical pathway for deploying real-time intrusion detection on low-power IoT devices, improving security at the network's edge.

Abstract Name: Growth Characterization of the Dissolved Silica-Tolerant Green Microalga *Micractinium* sp. for Biofuel Applications

Photosynthetic organisms such as microalgae and diatoms are being studied for sustainable biofuel applications. Co-culturing of photosynthetic organisms may increase biomass production, lipid accumulation, and flocculation efficiency of both organisms as they exchange nutrients and metabolites. However, diatoms

require dissolved silica to build their cell walls, but high silica levels can have inhibitory growth effects on microalgae. Because co-culturing microalgae with diatoms is a potential strategy to further enhance biofuel yield, understanding how both organisms respond to silica-rich environments is important. Hidden Lake Algae (HLA), or *Micractinium* sp., is a green microalga isolated from Hidden Lake in the Beartooth Mountains of Montana. Hidden Lake has a uniquely high dissolved silica level of around 0.3 mM. The lipid production of both xenic (with microbiome) and axenic (without microbiome) HLA was characterized using fatty acid methyl ester (FAME) analysis and shown to be at industrially relevant levels when compared to other microalgae. The dissolved silica tolerance of xenic and axenic HLA cultures were evaluated through dose response with no obvious difference up to 2 mM Si content. Currently, experimentation is in progress to determine the optimal pH range for HLA growth at high silica levels, with acidity effecting silica solubility. Sequencing of Hidden Lake environmental samples is in progress along with diatom enrichment for future co-culture experimentation of HLA and Hidden Lake diatoms. The high silica tolerance of HLA may facilitate a productive microalgae-diatom collaboration, offering a promising boost to biofuel production.

Abstract Name: Researching and Disseminating the History of Community Gardens in Underserved Neighborhoods

Accounts of vacant lots in low-income, inner-city neighborhoods examine these spaces as blighted results of foreclosures and city disinvestment. “Single stories” of urban decline fail to disseminate accounts of resilience and survival in these neighborhoods. Since 2012, the Buildings-Landscapes-Cultures public humanities project at UW-Milwaukee has been disseminating counter-narratives that highlight community survival in the face of difficulty. This project examines the experience of researchers who worked with residents in the Walnut Hill Community Garden on Milwaukee’s north side from 2023-2025 to facilitate community development and engagement and collect and disseminate qualitative neighborhood data. Through long and short form interviews, ethnographic data collection, and iterative engaged processes, the research team was able to better understand the lived experience of the community. Residents led us on walks through the garden, the surrounding neighborhood, and local abandoned industrial sites. We recorded accounts of community experiences, changes residents have seen through time, and dreams residents hold for the future. We identified issues and vital knowledge that would otherwise not be available to us if we examined quantitative demographic data. We came to understand how past, present, and future are intertwined. We recorded residents’ memories of the neighborhood, what used to occupy the garden lot, and how they claimed the land back as their own. Participating in engagement and mutual aid events helped researchers form lifelong connections with the people they worked with. With community members, we designed resource products around engagement and neighborhood history, and produced asset, vision, and tenant resource guides. These encouraged a continued conversation around the garden and its role. We end with a hope that engaged and iterative research methods will continuously explore ways to give back the collected history of the neighborhoods we work with and allow undergraduate students to apply their knowledge to address real life situations.

Abstract Name: A Weekly Project Newsletter to Engage Episodic Participants in OSS Projects

Open Source Software (OSS) projects increasingly depend on a diverse set of contributors, including episodic participants who contribute intermittently. Episodic contributors represent a large portion of OSS communities, yet projects often struggle to retain them, leading to decreased project health and continuity. While dashboards and real-time communication tools support continuously active contributors, they often fail to serve the unique needs of episodic participants, who may struggle to remain informed and re-engage with project activity after periods of absence. In this study, we examine the effect of a weekly, email-based newsletter intervention designed to improve awareness and engagement among episodic OSS contributors. We ground our approach in self-determination theory, emphasizing autonomy, competence, and relatedness as key motivational constructs. To inform the design of the Weekly Project Newsletter, we conducted a systematic literature review, followed by a think-aloud study with OSS contributors, leading to a refined newsletter that summarizes recent activity in issues, pull requests, and commits, and highlights project milestones and community interactions. We evaluate the final design of our Weekly Project Newsletter through a three-week diary study involving nine episodic contributors, analyzing how its content affected their awareness, motivation, and re-engagement patterns. Our findings show that the newsletter improves participant awareness and perceived project connection. These findings highlight how theory-driven communication tools can complement existing OSS infrastructure by supporting re-engagement and lowering the barrier to continued participation. However, its influence on OSS contribution behavior remains limited without actionable prompts or surfacing of beginner-friendly tasks.

Abstract Name: Visualizing Inequality: The Utilization of Cinematography as Social Commentary in Parasite (2019)

This project investigates how the director Bong Joon-Ho and cinematographer Hong Kyung-pyo use cinematography in the movie Parasite (2019) as a rhetorical device to convey the central themes of the movie—namely, social inequality and class struggle. The overarching question guiding this project is: How do the filmmakers utilize compositional elements such as framing, space, lines, blocking, color, movement, and lighting to visually represent social classism and inequality? Parasite (2019) solidified its cultural impact in 2020 when it became the first non-english film to win ‘Best Picture’. Unfortunately, the true brilliance behind the film may be lost on the average, casual movie watcher who may misinterpret the movie as another “great thriller, with some hints of comedy” or recognize the surface level metaphors that point towards class struggle. The mistake in this approach is that they are overlooking the craftsmanship of visuals that gives the moments in the film power. This presentation will provide an in-depth close-reading of 8 stills from Parasite, focusing on how the visual design elements including color, lighting, and space show the way the film applies visual rhetoric to connote meaning. Analyzing these stills will allow the audience to fully comprehend how cinematography is used to show the film’s themes of social inequality and class struggle. Too often, movie

viewers engage in thematic interpretation from a surface level perspective. As a result, they are not experiencing film to the fullest, most engaging potential. By reading this visual analysis on the movie Parasite (2019) audiences can gain needed perspective needed to better understand and appreciate how films tell stories.

Abstract Name: Accelerating Mission Design: Alpha-Beta Control Method Applied to Guidance and Control in Earth Re-Entry Missions

The industry standard for spacecraft atmospheric reentry is the Apollo Guidance, Navigation, and Control (GNC) system; however, this system only works well for blunt spacecraft with simple aerodynamics. As spacecraft become more complex the need to investigate other options increases. This project investigates whether the alpha-beta control method, with control of angle of attack and sideslip, can provide an updated alternative to the Apollo GNC. We examine the Alpha-Beta control system in reentry and attempt to benchmark its performance against the legacy industry standard, the Apollo (GNC) system. We predict that the ability to control the angle of attack and sideslip angle will offer an advantage compared to Apollo's control of bank angle. We have developed a full-scale 3-degree-of-freedom reentry simulator to determine the optimal guidance and control method. The simulation works by generating a reference trajectory and minimizing the distance error between it and the actual trajectory through reentry. The following assumptions are made to simplify the problem: point mass, constant mass, non-rotating planet, no thrust, drag acts in the direction opposite to velocity, lift is perpendicular to velocity, and gravity is directed along a vector from the point mass to the center of the planet. Results indicate that alpha-beta reduced distance error marginally. Error convergence plateaued on the order of 10^5 meters, well above the <20 km expectation. Analysis suggests the limitation originates from insufficient lift vector control. These findings indicate that alpha-beta alone is not a viable replacement for the Apollo GNC; however, it may serve as a complementary system if integrated with bank angle regulation. Future work includes implementing bank angle control coupled with angle of attack and sideslip, and testing various planets' atmospheres. This study showcases one of the first benchmarking attempts comparing Apollo GNC to the alpha-beta method and advances spacecraft atmospheric reentry

Abstract Name: Language Barriers and Pediatric Pain Management

Abstract Background and Significance: In America, 22% of households speak a language other than English. This transfers easily to healthcare as the field becomes increasingly diversified. Language barriers in limited English proficiency patients (LEP) are linked to undocumented pain scores, lower analgesic use, and higher readmission rates in LEP children. Previous studies have evaluated interventions such as integrating bilingual education into nursing curriculum, integrating interpreter training and collaboration into nursing simulations, and modifying pediatric pain tools. The integration of interpreter training into nursing simulation has shown

positive results; increased confidence in communicating with LEP populations, improved empathy, cultural competence, and teamwork with interprofessional teams. Leininger's Culture Care Theory emphasizes the integral role of culture in providing effective, congruent care. Language is a major part of culture and cannot be ignored and must be included in patient care. Aim: The aim of the project is to assess students' confidence and preparedness in working with interpreters and LEP patient populations. Method: This Evidence-Based Practice project will integrate nursing training simulations to teach and prepare students to collaborate with interpreters and work with LEP pediatric patient populations, using surveys of student and interpreter feedback to determine the simulation's effectiveness. In addition to measuring pre- and post-test assessments of language and communication knowledge, interpreters will use a competency checklist, pain assessment accuracy, and self-efficacy scales. Conclusion: Pediatric Patients with LEP experience inadequate care compared to their English-proficient counterparts. Pain management is a human right deserved by all patients regardless of culture or language. In integrating interpreter training in nursing simulation practice, it is expected to increase nursing students' confidence in working with interpreters and the LEP patient population, as well as cultural competence. Keywords: Limited English Proficiency, Health Equity, Language Barriers

Abstract Name: Relationship Between *Australopithecus Afarensis* and Intermediate *A. anamensis/afarensis*

Understanding the relationship between late *Australopithecus anamensis*, intermediate *A. anamensis/afarensis*, and early extinct *Theropithecus* (~3.9 Ma) at the Woranso-Mille site in the Afar Region of Ethiopia provides insight into the environmental and ecological context preceding the emergence of *A. afarensis*. During the early to mid-Pliocene, Eastern Africa experienced a transition from humid, closed woodlands to increasingly dry, open shrub-grassland ecosystems with heightened seasonality. At Woranso-Mille, hominin fossils are comparatively rare, whereas *Theropithecus* remains are abundant. This raises the question of whether ecological interactions, particularly competition or niche partitioning between hominins and fossil cercopithecines, contributed to paleobiological changes within early *Australopithecus*. This project synthesizes peer-reviewed literature to compile morphological and paleoenvironmental data relevant to these taxa across time. Faunal assemblages from early Woranso-Mille indicate a predominance of arboreal and semi-arboreal species, with few carnivores, suggesting mosaic habitats of closed floodplain woodland adjacent to shrub-dominated grasslands. These reconstructions align with evidence that *A. anamensis* was an obligate biped primarily associated with C3 woodland resources, while stable isotope analyses of *Theropithecus* dentition indicate a heavily C4-based diet (approximately 35–40%) (Include a source). Paleoenvironmental indicators such as pollen and plant wax isotopes further document increasing aridity and expansion of C4 grasslands through time. Notably, hominin remains tend to occur near woodland margins surrounding alkaline lake systems. The combined environmental and faunal evidence suggests that climatic shifts toward more open, arid landscapes may have reduced suitable habitats for early hominins, contributing to population declines or local extirpations in the region.

Abstract Name: Deconstructing The Bear: Reconceptualizing Masculine Archetypes & the Importance of Brotherhood

The Bear, which began airing in June 2022 on FX/Hulu, is a drama show that explores how guilt rooted in generational trauma alters one's perception of themselves, male emotional isolation and the importance of family: both found and of blood relation. Traditional depictions of brotherhood, seen in shows such as Suits, You, and The Office, depicts masculinity as a constant competition and assertion of dominance between males rather than a relationship where men can come together and talk; holding each other accountable for past mistakes, or searching for guidance from a place of understanding not judgement. In this paper, I argue that The Bear offers a more nuanced perspective that centers masculinity through the reconfiguration of community after grief. The Bear explores the relationship between legacy, family, and culinary experience, and showcases significant progress in developing media representations of masculine identities. It underscores that masculinity exists outside of oversimplified stereotypes while simultaneously humanizing men by showing the complexity of their emotional cores. This paper consists of a close textual analysis of Season 1 and Season 2 of The Bear via watching the show and reviewing transcripts of all episodes. I observe the visual storytelling and cinematography of the show in order to deconstruct the male-main character's portrayal of masculinity. I found that The Bear uses the ugly parts of what society has constructed of manhood as commentary, evolving tropes around male aggression and violent outbursts. The show takes a cognitively distant approach to these displays as demonstrations of deconstructed gender overperformance. As a means of creating representation, television enters to make masculine archetypes with which audiences can align. This show offers an alternative to the current oversaturated depiction of unhealed trauma and emotional stagnation existing in male characters, by portraying positive masculine representation that can affirm viewers.

Abstract Name: The Development of a Pre-Admission Writing Program for Incoming Nurse Anesthesia Doctoral Students

Resident registered nurse anesthetists (RRNAs) are registered nurses (RNs) enrolled in a graduate nursing program. Typically, a Doctor of Nursing Practice (DNP) or Doctor of Nurse Anesthesia Practice (DNAP) program. These programs require a higher level of academic writing skills than undergraduate programs. The goal of this project was to develop a self-directed online pre-admission writing course to improve the writing ability and self-efficacy of incoming RRNAs. A mixed-methods design was employed over two academic years, a pilot phase (2023) and a formal evaluation phase (2024). Both cohorts of RRNAs were included in the sample: 55 students from the 2023 cohort, and 61 from the 2024 cohort. The intervention consisted of an 8-week asynchronous Canvas course, grounded in adult learning theory and self-directed learning principles. The Situated Academic Writing Self-Efficacy Scale (SAWSES) and the CUNY Assessment Test in Writing (CATW) were used to assess the program's efficacy. And the program acceptability was evaluated using the Theoretical Framework of Acceptability (TFA) questionnaire. The 2024 cohort exhibited higher engagement with a 90% completion rate and consistent post-intervention gains across all SAWSES domains. The 2023 cohort achieved a 58% completion rate but showed inconsistent self-efficacy outcomes. There were measurable improvements in writing performance (CATW scores) for both cohorts, with the 2024 cohort demonstrating greater proficiency in idea development and structure than the pilot cohort. In 2023, 19 themes were identified among responses to the TFA, and in 2024, 15 were identified. In 2023, 11 themes were identified in the SAWSES pre-intervention responses and 12 in the post-intervention responses. In 2024, 12

themes were identified both pre- and post-intervention. The CATW identified 15 themes in the 2023 cohort's writing, and 22 in the 2024 cohort's. Refining the curriculum improved engagement and outcomes, suggesting that a pre-admission writing program effectively enhances RRNAs' scholarly abilities.

Abstract Name: Modeling the Predictors of Childcare Availability: Evidence from St. Louis County

The availability of affordable, high-quality childcare remains a growing concern across the United States, with many communities facing persistent shortages that affect family stability and local economic growth. This project examines how demographic and economic characteristics shape the distribution of licensed childcare centers, using St. Louis County as a focused case study. St. Louis County provides an ideal setting for this analysis because it includes municipalities with substantial variation in population density, income levels, and childcare demand, allowing for meaningful comparisons across local areas. Using publicly available data from state and federal sources, the study develops a regression model to identify which county-level factors are most strongly associated with the number of licensed childcare providers. The analysis will concentrate on a core set of measurable predictors, including the number of children under age five, median household income, and indicators of the childcare workforce. Additional variables, such as the average cost of care or staff vacancy rates, may be incorporated as data availability allows. This measured approach ensures a feasible and focused model while still capturing the most influential drivers of childcare access. The findings aim to provide evidence-based insights that can inform policy recommendations to expand childcare availability. Potential applications include targeted support for providers, zoning or regulatory adjustments that reduce barriers to opening new centers, and increased public investment in early childhood infrastructure. By highlighting which community characteristics are most closely linked to childcare supply, this project contributes to a clearer understanding of how local demographics and economic conditions shape the childcare landscape and how policymakers can more effectively respond to ongoing shortages.

Abstract Name: In the Name of God: Christian Nationalism, Political Extremism, and the New Face of Terrorism

In the United States, Christian nationalism does not just shape politics, it discretely redraws the line between a “patriot” and a “terrorist.” This research examines how, from Donald Trump’s 2016 election through the present, Christian nationalism in the United States reshapes political extremism and what we are willing to name as “terrorism,” while tracing its roots through further histories of settler colonialism and state violence against Indigenous communities in North America. Rather than treating Christian nationalism as only a set of beliefs, I approach it as a political regime that fuses national identity, race, and power; asking how leaders and organizations define a “Christian nation” and how that language justifies increasingly extreme actions. Employing a mixed-methods research approach, I combine historical and legal analysis, media analysis, and qualitative case studies of historical events and documented acts of violence. I examine how the media,

politicians, and law enforcement label or refuse to label Christian nationalist violence as terrorism, compared with other religious or ideological violence, in the name of God. I also analyze how race, immigration, Indigenous sovereignty, and “Western civilization” narratives shape who is imagined as a terrorist, and where gaps in domestic terrorism law allow religiously coded extremism to go unnamed and/or unpunished. Using an intersectional framework, I dissect the impacts of how consistently naming Christian nationalist violence as terrorism might transform public understandings of security, democracy, and political legitimacy in the United States.

Abstract Name: Voices on AI: Student and Instructor Perspectives

The increasing use of Artificial Intelligence (AI) tools has transformed higher education, and research is just beginning to explore people's attitudes and usage of AI, particularly in educational settings. The purpose of this survey is to find how university students and instructors use AI in both academic and non-academic contexts. We will also measure their attitudes and comfort with AI and relationships between attitudes and use. The participants will be university students and instructors completing a survey using Qualtrics. Participants will report their role in the university (student or instructor), the frequency and tasks they use AI for (both academic/work and non-academic such as budgeting), provide open-ended responses on how they use AI, and indicate their overall attitudes to a series of statements about AI (e.g., excitement, privacy concerns, perceived impact). Survey questions have been finalized and recently approved by the Institutional Review Board (IRB). Data collection will begin in mid January. The frequency of AI usage is hypothesized to positively correlate with positive attitudes toward AI, and negatively correlate with concerns about privacy or potential educational harm. Students are expected to report higher usage and more optimistic attitudes toward AI than instructors. Patterns on how AI is used will also be summarized. These results can help provide insight into how students and instructors are adapting to the growing tool of AI. Understanding these differences can help educators integrate AI in a way that can enhance learning while maintaining academic integrity and knowledge of AI security. As AI becomes increasingly utilized in higher education settings, identifying feelings of AI use across academic roles will be critical.

Abstract Name: Mindfulness does not protect against mental health concerns associated with passive social media use

Passive social media use is linked to increased anxiety and depression, fear of missing out (FOMO), and social comparison. The purposes of this study were to investigate passive social media use in relation to mental health, FOMO, and social comparison, and to examine mindfulness as a moderating variable in the relationship between passive use and mental health. The main hypothesis here is that mindfulness will moderate the positive relationship between passive social media use and mental health problems. This is

important as mindfulness could help combat the harmful mental health impacts of passive social media use, and there is little research on this topic. A correlational study was conducted with eighty-five participants who answered questions regarding their levels of anxiety, depression, FOMO, social comparison, passive social media use, and mindfulness. Results revealed that passive social media use was positively correlated to anxiety, depression, and FOMO, but negatively correlated to social comparison. Passive use was negatively correlated to mindfulness. This largely supports the hypothesis, aside from social comparison. Active social media use, in contrast, was uncorrelated with mental health and social comparison variables, though it was positively related to FOMO. Contrary to predictions, mindfulness was not a significant moderator of the relationship between passive use and anxiety, or passive use and depression. These findings suggest that mindfulness is not a sufficient buffer against mental health issues resulting from passive social media use. In contrast, active social media use was found to be unrelated to mental health concerns. Current research is in progress to explore these possible relationships using a mindfulness intervention, and results will be presented at the research conference.

Abstract Name: What Students Find Helpful About 'Psychology as a Profession': A Thematic Analysis of Career Development Reflections

Many undergraduate students struggle with making decisions relating to their majors. They report that they are not feeling confident in their knowledge of potential career paths related to their field of study. Only a small percentage of students are aware of the career services, and a smaller percentage of students actually use those services. A total of 93% of the students who are taking career-focused courses report changing their career plans. After taking these courses, students also report feeling more confident and educated about their career decisions and the opportunities available. Studies show career-exploration classes have the largest effect on career outcomes compared to other career interventions. We want to know what exactly it is that students find helpful about their career-focused course. We will conduct a thematic analysis of survey responses we got from four open-ended questions of 225 undergraduate students from a large public university, in the southeast of the United States, who were enrolled in a mandatory career-focused course (Psychology as a Profession). I hope that this analysis will allow me to identify important patterns and certain themes regarding career literacy, enhanced self-efficacy in decision-making, a more well-rounded knowledge of psychology, and overall increased knowledge/confidence in psychology careers.

Abstract Name: Belonging Beyond Borders: Interfaith Leadership in Contested Migration Landscapes

Amid a sociopolitical climate marked by rising anti-immigrant sentiment and increasingly exclusionary policy frameworks, faith leaders continue to navigate a complex terrain where religious tradition meets civic responsibility. Operating at the intersection of faith-based practice, humanitarian response, and political resistance, rabbis, imams, priests, and other spiritual leaders have become central actors in supporting

displaced communities across the United States, providing immediate care and vital resources. This project will use storytelling, oral history, and photographic documentation to examine how interfaith leaders, particularly those in Sanctuary Cities facing heightened hostility, respond to the needs of asylum-seekers, refugees, and undocumented individuals. By engaging both community leaders and the migrant communities they serve, the project aims to illuminate stories of resilience, solidarity, and advocacy within contested political landscapes. Oral history interviews will allow narrators to share the lived experiences of populations too often marginalized in policy debates and media narratives. These testimonies will capture the everyday realities, aspirations, and challenges of displaced populations, offering a nuanced understanding of migration beyond statistics or political rhetoric. Photography will function as a complementary narrative form, building a visual archive that situates these stories within place, identity, and memory. Together, these methods will not only aim to preserve memory but also capture how interfaith networks can cultivate care, protection, and collective resistance. By documenting these intertwined narratives, the project seeks to contribute to broader dialogues on migrant justice, highlighting how future policies might be shaped by empathy, community knowledge, and the lived experiences of those most affected. Empathy, in this context, becomes an essential lens that expands policy evaluation to include dignity, safety, well-being, and long-term community impact. This project, therefore, asks: What strategies do interfaith leaders employ to cultivate practices of solidarity, care, and advocacy that reimagine belonging and reshape conversations about migration within contested political landscapes?

Abstract Name: Tolerance of Copper Treated Plants by *Pieris rapae* Caterpillars

Although agricultural practices aim to meet the requirements of our growing population, continuous agricultural activity has increased the contamination of heavy metals in the environment. The levels at which they are currently present are toxic to both the plants and the specialist herbivores that consume them. While many studies have conducted research on the effects of HM contamination on the performance of *Pieris rapae* butterflies, a common agricultural pest, few have observed the effects of HM based pesticides on such organisms. Our research focuses on the effects that copper pesticide use has on the growth and survival of *P. rapae* larvae at the 4th and 5th instars. This study was conducted using a no choice leaf experiment over 3-day periods split into small segments of 24 hour data collection sections, with a total of three 3-day experiments. The setup consisted of 2-3 *P. rapae* caterpillars placed in dishes on small *Brassica oleracea* clippings. The clippings were treated via spray with one of two solutions, at different concentrations, of Captain Jack's copper fungicide and a control with untreated (water sprayed) leaves. To measure performance in terms of growth, all caterpillars were weighed before and after each 24 hour segment, survival was recorded after every segment as well. Dead caterpillars were also measured to account for weight changes that could indicate poor survival. Our experiments found that caterpillar weight was negatively affected by the fungicide treatment, but there was no significant effect on caterpillar mortality. Future research should aim to examine and observe the behavioral plasticity of *P. rapae* caterpillars when forced into conditions at different copper pollution levels to further our understanding regarding the effects of pesticide use on ecological life.

Abstract Name: Analysis of Benzophenanthridine Alkaloids in Black Salve Medicinal Supplements via Liquid Chromatography-Triple Quadrupole Mass Spectrometry

Ointments and creams collectively known as black salves have been used to treat various skin conditions since the 19th century. Black salves have been promoted as alternative treatments for benign lesions such as moles and skin tags, as well as for serious conditions including skin cancer. However, despite their longstanding use, there is no scientific evidence supporting the efficacy of black salves for any dermatological condition. The FDA warns that these products can cause scarring, infection, and permanent disfigurement. Despite these risks, black salves remain widely available for purchase online. Furthermore, because black salves are marketed as supplements rather than approved medical treatments, they face limited regulatory scrutiny, and their exact chemical compositions often remain unknown. Black salve products are typically made from bloodroot (*Sanguinaria canadensis*) and contain benzophenanthridine alkaloids suspected to be the principal components responsible for tissue damage. Sanguinarine and chelerythrine, two biologically active benzophenanthridine alkaloids derived from bloodroot, are of particular interest. Liquid chromatography–mass spectrometry (LC-MS) is a powerful analytical technique suitable for characterizing these compounds. In this study, an LC–MS method using selected ion monitoring was developed to detect and quantify both sanguinarine and chelerythrine in a variety of black salve extracts. The resulting data will aid in determining the presence and concentration of these potentially toxic alkaloids in black salve supplements.

Abstract Name: Synthesis of 3-Hydroxylamine and 3-Hydroxyl Bis-Isatin Derivatives and the Investigation into Their Biological Activity

As people tend to live longer, the challenge with Alzheimer's Disease (AD) will only increase. Today around 55 million people worldwide suffer from the effects of AD, and the cost of providing care is around \$1 trillion. AD is characterized by brain degeneration of those afflicted, leading to loss of memory and cognitive abilities. Acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) inhibitors are being looked at for the treatment of AD, which still does not have a cure. Previous work in our lab has identified bis-isatins as selective BChE inhibitors. Ongoing studies have synthesized 3-hydroxyimino bis-isatins through condensation with hydroxylamine and 3-hydroxy bis-isatins through reduction with sodium borohydride. Preliminary inhibition results show promising activity with similar selectivity, and interactions with the enzyme have been predicted using computational docking. The full results of these ongoing synthetic and inhibition studies along with results of docking will be presented and add to the growing knowledge of these isatin-based molecules.

Abstract Name: A Comparative Study of Loki and Coyote as Cultural Tricksters

Few mythical characters more clearly reflect the good and bad aspects of human nature than Coyote from Native American folklore and Loki from Norse mythology. Both Coyote and Loki are tricksters and shapeshifters whose metamorphoses reflect the values, anxieties, and beliefs of the communities from which they originated. This study will examine how the myths surrounding Coyote and Loki shape their respective symbolic value in visual culture by examining artwork by artists who have brought these tales to life. Theodor Freund's bronze "Loki" depicts tension and intelligence, Mühlten Eskil Winge's "Loki and Sigyn" depicts divine anguish. Contemporary artwork such as Bob Haozous's "God's Favorite," Harry Fonseca's "Queer Coyote," emphasize modern interpretations of these ancient figures. These artworks show how trickster imagery continues to influence moral and cultural thought in their respective societies. A discussion of Coyote's transformational abilities will demonstrate how Native Americans perceive nature as fluid, cyclical, and intertwined with humans. Following analysis of Norse concepts of chaos, pride, and the precarious equilibrium between gods and giants will show Loki's transformations into animals like a fly, salmon, or horse. The comparative examination will demonstrate how both characters employ deceit and transformation not only to stir up trouble but to impart cultural and moral lessons about identity, power, and change.

Abstract Name: Studying the Relationship between System xc- and Calmodulin

System xc- a protein involved in glutamate and cystine exchange across the membrane- is known to exhibit increased activity in response to oxidative stress. A preliminary proteomics screen to identify proteins that interact with System xc- demonstrated that a calcium-sensitive protein, known as calmodulin, is often found associated with the transporter. Calmodulin regulates the trafficking and activity of several protein channels and is also recognized as a key regulator of protein function during oxidative stress. Therefore, this project aims to understand the relationship between System xc- and calmodulin. Using consensus sequence analysis, we identified putative calmodulin binding sites on the N and C-terminus, and we are using site-directed mutagenesis to determine how disruption of each of these sites alters System xc- function, cellular localization, and association with calmodulin. Thus far, we have assessed K43, I16, V24, I10, and V20 and have discovered that transport activity is reduced when either I10 or V20 is mutated to glutamate. These data are particularly intriguing, as hydrophobic residues spaced 10 amino acids apart are common consensus binding sites for calmodulin, suggesting that I10 and V20 may serve as such a site on xCT. Moreover, we have examined the calcium sensitivity of System xc- given that calmodulin often binds in a calcium-dependent manner. We have observed that when calcium is included in the extracellular solution, System xc- activity increases relative to that when calcium is not included in the extracellular solution. We are currently determining whether the presence of calcium impacts the association of System xc- and calmodulin in vivo. Once completed, this study will unveil potential novel mechanisms by which System xc- is regulated during times of oxidative stress.

Abstract Name: Interaction Between Geographic Location, Alcohol Use, and Depression/Anxiety/Stress in College Students.

Geographic location has been shown to influence mental health, with individuals in rural areas experiencing poorer mental health than those in urban areas. Adolescents in rural communities are more likely to meet criteria for alcohol use disorder. Several factors could explain this such as familial influence, geographic isolation, and limited recreational activities. Potential risk factors of rurality are known. However, there is a significant lack of research on the effects of rurality on college students. Many studies have examined alcohol use in college populations. However, many of them do not specify rural vs urban campus location as a variable. This research seeks to contribute to limited literature on alcohol use and rates of anxiety/depression/stress college students who live in rural areas may face. A community sample of college students from a Maryland university will be asked questions regarding the geographic location they have spent the most time in, alcohol abuse, depression, anxiety, and stress in an online survey. Students will also be questioned about family and personal history of mental health. T-tests with Bonferroni corrections will be used to evaluate the mean differences in these two related outcomes for our two regional categories. We expect higher rates of alcohol use and lower rates of formal mental health diagnoses in people from rural environments compared to those in urban environments. However, we do not anticipate significant differences in rates of depression, anxiety, and stress levels among these two groups.

Abstract Name: Integrating Hardware Fabrication and Visuomotor Policy Learning for Robotic Manipulation

Recent advances in learned robotic manipulation have demonstrated impressive capabilities in industrial, healthcare, and defense domains. However, applications in these domains usually require expensive hardware inaccessible to most researchers. In this work, we address this gap by demonstrating that effective control policies can be trained and deployed on hardware fabricated with accessible university resources, enabling broader access to robot learning research. We develop an end-to-end pipeline for autonomous robotic manipulation, integrating hardware fabrication, hardware-software integration, and machine learning to train visuomotor policies directly from human demonstrations on low cost open-source hardware and software. Our setup uses SO-101 robotic arms with a 6-DOF design, printed using makerspace facilities and assembled with twelve STS3215 servo motors, motor controllers, and power distribution systems sourced through the university resources. In our pipeline, motor controller boards manage servo motor control through position commands and encoder feedback via UART serial communication. A leader-follower teleoperation configuration captures demonstrations by synchronizing joint trajectories with RGB image sequences. The software architecture employs a machine learning framework based on LeRobot and d3rlpy to predict future

joint targets conditioned on visual and proprioceptive input. The demonstrations are processed into datasets and used to train policies via offline reinforcement learning on an NVIDIA T4 GPU, which are subsequently deployed for real-time control on consumer-grade hardware. Evaluation focuses on household manipulation tasks such as pick-and-place, with expected results demonstrating reliable task completion despite hardware cost constraints. Future work will use and integrate NVIDIA Isaac Lab for sim-to-real transfer, leveraging offline-to-online reinforcement learning for adaptive policy selection. This pipeline enables rapid prototyping of learned control policies for application-specific hardware configurations.

Abstract Name: Biochemical and Biophysical Characterization of *Neisseria gonorrhoeae* Nucleoside Diphosphate Kinase (NDPK)

Neisseria gonorrhoeae, the causative agent of gonorrhea, poses a growing global health threat due to the rapid emergence of antimicrobial resistance (AMR). Novel therapeutic strategies are urgently needed to combat this pathogen. Nucleoside diphosphate kinase (NDPK) from *N. gonorrhoeae* (NgNDPK) represents a promising drug target because it catalyzes a key step in the nucleotide salvage pathway, which is essential for bacterial survival. NDPKs maintain cellular nucleotide homeostasis by transferring γ -phosphate groups from nucleoside triphosphates to diphosphates via a phospho-histidine intermediate. Despite previous characterization in model organisms, the structural and functional features of NDPKs from pathogenic bacteria remain poorly understood. Here, we report the structural and biochemical characterization of NgNDPK. The crystal structure reveals a tetrameric assembly, with each subunit adopting the canonical α/β -sandwich fold composed of a central four-stranded antiparallel β -sheet ($\beta 1$ - $\beta 4$) flanked by α -helices. In contrast, human NDPKs typically form hexamers. Sequence analysis identified key differences between NgNDPK and human NDPK isoforms, particularly within the catalytic kpn-motif involved in substrate binding and phosphoryl transfer. These findings provide new insight into the architecture and potential regulatory mechanisms of NgNDPK and establish a foundation for structure-guided inhibitor design targeting this essential enzyme in *N. gonorrhoeae*.

Abstract Name: Profits Over Public Health: Tobacco Industry Influence on Scientific Evidence and Regulation

The tobacco industry spends tens of millions each year lobbying the federal government, even as tobacco-related diseases cost the U.S. hundreds of billions in healthcare spending. This imbalance shows how corporations use economic power to shape policies that protect profits over public health. Sam Kean's *The*

Icepick Surgeon illustrates how similar patterns recur throughout history: institutions have often used scientific language to justify harm while defending their own interests. Although scholars have examined lobbying expenditures and regulatory capture, we still lack a clear understanding of how tobacco companies coordinate economic influence with manufactured scientific doubt to manipulate policy outcomes. Our research investigates how tobacco corporations use lobbying expenditures, revolving-door employment, and industry-funded research to influence policy decisions. We connect these strategies to the dynamics Kean describes, where scientific authority becomes a tool for maintaining power. Our literature search draws on databases such as JSTOR and policy documents and campaign finance records from federal government websites. Key search terms included “tobacco lobbying,” “regulatory capture,” “corporate influence,” and “policy manipulation.” Our analysis identifies three strategies companies use to shape policy. First, directing political contributions toward legislators on health committees to obstruct restrictive regulations. Second, funding research that creates uncertainty about tobacco’s harms, weakening scientific consensus and delaying public health protections. Third, cultivating insider relationships through revolving-door hiring, recruiting former regulators as lobbyists to shape rulemaking from within. Across these tactics, the industry frames regulation as an economic threat rather than a public health necessity, echoing Kean’s accounts of institutions that use authority and strategic messaging to shield harmful practices. At the same time, grassroots advocacy and evidence-based policy initiatives are pushing back. Understanding these strategies shows how economic power enables systemic manipulation and informs potential reforms such as campaign finance regulation, limits on revolving-door employment, and independent research funding.

Abstract Name: The Bioconversion of Bilirubin to Urobilin as a Potential Driver of Colorectal Cancer

Colorectal cancer is the third most diagnosed form of cancer in the world with 1.5 million new diagnoses and 800,000 deaths every year. Bilirubin is a product of heme metabolism with antioxidant and hormonal properties which is excreted as conjugated bilirubin. Within the gut microbiota, conjugated bilirubin is converted to urobilin which currently has no known physiological functions. Bilirubin has been negatively associated with all forms of cancer except colorectal cancer while urobilin is an important biomarker for the diseases. The goal of our research was to investigate the effects of bilirubin and its derivative compounds on cancer cell proliferation and metastasis pathways. We hypothesized that bioconversion of bilirubin to urobilin is correlated with colorectal cancer risk. We treated Caco2 colorectal adenocarcinoma cells with DMSO as the vehicle bilirubin, conjugated bilirubin and urobilin. We determined cell viability and proliferation using growth assay and cell migration using the scratch assay. We discovered that urobilin and conjugated bilirubin increased cell migration but not proliferation while bilirubin reduced both. In conclusion, these results suggest that the conversion of bilirubin to urobilin in the colon may be a driving factor for colorectal cancer progression and more studies are needed to better understand their mechanisms.

Abstract Name: Analytical Study of Machine Learning Models for the Detection of Potholes

The goal of this research is to evaluate the reliability of machine learning models in image-based pothole detection. Using Ultralytics YOLOv11 (You Only Look Once), a real-time object detection model optimized for both accuracy and speed, multiple models were developed and analyzed under varying environmental conditions. The study focuses on understanding how factors such as lighting, weather, and camera quality affect detection performance. To test these conditions, individual models were trained on datasets representing day, night, and rainy environments, as well as a combined dataset encompassing all three. A major challenge identified was the occurrence of false positives, instances where the model detects a pothole that does not exist. This issue poses a significant concern for real-world deployment, as misidentifications could trigger unnecessary alerts or responses in safety-critical systems such as autonomous vehicles. To ensure robust experimentation, models were trained using a high-performance computing setup featuring an NVIDIA GeForce RTX 2060 GPU, Intel® Core™ i9-14900K processor, 128 GB of memory, and 2 TB of storage, achieving maximum training efficiency with sessions averaging 27 hours. Two primary optimization techniques were applied: optimal loss weighting (adjusting weight distribution to improve generalization) and hyperparameter tuning (refining model parameters for performance stability). Results indicate that balanced loss weighting enhanced the model's ability to understand entire scenes beyond simple bounding boxes, while momentum tuning led to smoother and faster convergence. Adjusting confidence thresholds also reduced false positives with only a minor decrease in recall. This analytical study highlights how tuning strategies can improve reliability and performance in pothole detection models, contributing to safer and more trustworthy intelligent transportation systems.

Abstract Name: Socio-Environmental Life Cycle Assessment on Vanadium Production

This project examines the effects that Vanadium Oxide (V_2O_5) producing mines have on the surrounding environment and nearby communities. This will be done through a Life Cycle Analysis (LCA) of mineral production. These analyses are typically conducted from cradle to grave, meaning the analysis encompasses the collection, production, and distribution processes. However, this project will primarily focus on the collection and production portions of the LCA. The socio-environmental ramifications of Vanadium mines were quantified using historical databases of mines operating from as early as 1900 to 2014. Process pathways were examined based on metrics designed to determine which techniques of ore extraction are the most environmentally friendly. Emissions such as wastewater, noxious gases (CO_2 , HCl , SO_2), water depletion, solid waste, airborne dust, and others were taken into consideration. Using a combination of these inputs and metrics, we then constructed process flow diagrams outlining the inputs and outputs associated with each pathway of Vanadium Oxide extraction. Techniques such as sodium roasting, calcium roasting, and sub-molten salt processing were evaluated, and through this examination we identified the pathways that are most environmentally sustainable while still remaining cost and energy efficient. In essence, this Vanadium LCA can be used to encourage large corporations to employ safer practices that cause the least amount of harm, as the demand for V_2O_5 rises, so too should efforts to optimize these processes for the planet and for the local communities who bear the environmental consequences.

Abstract Name: Learning vs. Logic: A Comparative Analysis of Deep Reinforcement Learning and Heuristic Pathfinding

As AI becomes a more commonly used tool among businesses, social media, creative fields, and various other networks, understanding the optimal algorithms for specific environments becomes equally important. This research investigates the efficacy of “learning-based” approaches and traditional “heuristic-based” pathfinding. This study will utilize the OpenAI gymnasium library to simulate the classic game “Snake”, providing a standardized environment for testing AI agent adaptability in a stable environment. We will implement and compare three different algorithms: The Deep Q-Network (DQN) algorithm, a reinforcement based learning algorithm implemented by using Python and PyTorch; the A-Star search algorithm based on mathematics, and the greedy best first search algorithm, a heuristic approach that prioritizes speed and simulates human “naive” behavior. The algorithms will be evaluated based on the AI agent's ability to achieve a high score, how long it can survive, and the overall efficiency. We hypothesize that the A-Star algorithm should have consistent high scores thanks to its mathematical approach, the DQN algorithm will start weaker than the “heuristic-based” approach but will eventually outperform it thanks to its learning capabilities. Based on this we can reason that the greedy algorithm will serve as a baseline for lower performance. This project ultimately aims to conduct research on modern machine learning using classical computer science theory in the form of algorithms.

Abstract Name: Biological, Social, and Environmental Determinants of Allostatic Load in Black Woman.

This project examines how biological, social, and structural-environmental stressors shape the long-term health of Black women. The central aim of this research is to identify novel markers of health disparity within this population, using allostatic load as a key outcome measure. Allostatic load captures the cumulative physiological burden produced by chronic stress and has become an essential lens through which to understand racialized health inequities. Black women in the United States experience accelerated health deterioration, often described as weathering, driven by socio-economic pressures, behavioral demands, and persistent structural inequalities. This phenomenon has been linked to elevated mortality, pregnancy complications, and disability. While Black and Latina women consistently demonstrate the highest allostatic load scores, the mechanisms behind these disparities remain insufficiently understood. Daily stress exposure, neighborhood conditions, and environmental toxicity may jointly shape these outcomes, yet their interplay requires deeper investigation. To explore these relationships, we conducted a cross-sectional analysis using data from the National Health and Nutrition Examination Survey, a nationally representative sample. Allostatic load scores were calculated from individuals in the highest-risk quartile for pulse, C-reactive protein, urine albumin, glycohemoglobin, systolic and diastolic blood pressure, total cholesterol, and high-density lipoprotein. Demographic, laboratory, and examination variables were assessed for associations with elevated allostatic load. Sub-analyses were performed by sex and race/ethnicity, and associations were evaluated using Spearman's rank-order correlation with adjustment for multiple comparisons. Initial results

confirmed marked disparities in allostatic burden across sex and racial/ethnic groups. Significant positive correlations emerged between allostatic load and exposure biomarkers of blood lead and cadmium. We hypothesize that these relationships may be modified by sex and race/ethnicity. These findings highlight the importance of integrating biological, environmental, and social determinants when studying chronic stress. Understanding these interactions can inform effective public health strategies and interventions that reduce disparities among vulnerable communities.

Abstract Name: Racial Differences in the Relationship Between Maternal Smoking, Cesarean Delivery, and NICU admission.

Maternal smoking during pregnancy stays consistent as a preventable risk factor associated with negative neonatal outcomes, yet racial disparities concerning these outcomes still persist. This study examines whether maternal smoking during pregnancy is associated with admission into the neonatal intensive care unit (NICU), and whether cesarean delivery is a mediator in this relationship. This study will focus on the differences between non-hispanic black women, and non-hispanic white women. 2024 national birth certificate data will be used to evaluate the associations, including live, singleton births from non-Hispanic Black and White women. Multifetal pregnancies, other racial/ethnic groups will be excluded. Key variables include any smoking during pregnancy (primary; trimester specific smoking (secondary) as exposure, cesarean delivery (planned/unplanned/emergency) as mediator, NICU admission (YES/NO) as outcome, and maternal age, education, pre-pregnancy BMI, etc as some major confounders. This project's aim is to evaluate the direction and strength of the association between NICU admission and smoking to establish whether the mode of delivery somewhat explains this relationship. In conjunction, this study examines whether these associations present key differences between non-Hispanic Black and non-Hispanic White women, contributing to an in-depth understanding of racial disparities in infant and maternal health outcomes. This research is in progress. My role includes designing the study, selecting variables, refining the research question with the guidance of a research professor, examining birth certificate data, and developing the framework of a research article. By defining whether cesarean delivery acts as a mediation, this study may assist to inform clinic decision making and strategies in public health aimed at lowering NICU admissions while addressing racial disparities concerning perinatal care. Overall, the findings of this study may help improve maternal and infant outcomes across diverse populations with targeted interventions.

Abstract Name: Assessing the Presence of Microplastics in Jug Bay

In recent years, the presence of microplastics in marine environments is becoming an area of increased

environmental concern. Aquatic habitats act as a final sink for the improper disposal of plastic waste. The conditions of these environments easily degrade plastics and transport them to large bodies of water that support life around the globe. As the size of microplastics decreases, their toxicity, likelihood of being consumed increase, and ability to absorb contaminants increases. The Patuxent River, which provides drinking water to thousands of Maryland residents and acts as shelter to a variety of aquatic and terrestrial species, suffers from this issue as well. However, there are significant gaps in knowledge around the concentrations of microplastics in this river. This project explores 2 methods of analyzing microplastics in Jug Bay, a tidal estuary along the Patuxent River.

Abstract Name: The Literacy Divide: A Global Literature Review of K–8 Reading Performance During COVID-19 School Closures

The COVID-19 pandemic led to prolonged school closures, raising concerns about reading outcomes among K-8th-grade students. This review investigates international and U.S. research on how socioeconomic status, marginalization, and teacher preparedness affected student academic reading performance during closures. Eleven peer-reviewed longitudinal, mixed-methods, and cross-cohort peer-reviewed studies published between 2020 and 2024 were analyzed. Lower socioeconomic status students consistently showed larger discrepancies in academic reading scores, marginalized communities experienced exacerbated learning losses, and teacher readiness notably improved by the second set of COVID-19 school closures. These findings underscore the need for programs and initiatives that target technology access, differentiated teacher training, and policy interventions to decrease the marginalization of communities in order to avoid reading gaps and variables caused by socioeconomic status.

Abstract Name: Prolonged Endurance Exercise Enhances Insulin Sensitivity and Alters Adiponectin During Recovery

Purpose/Hypothesis This study examined how marathon running affects circulating adiponectin and insulin, two hormones involved in lipid metabolism and glucose regulation. Adiponectin promotes fatty acid oxidation and increases insulin sensitivity, while insulin regulates glucose uptake and storage. Understanding how these hormones respond to prolonged endurance exercise can provide insight into post-exercise metabolic recovery. We hypothesize that insulin will show an immediate reduction after the marathon, while adiponectin will increase during the recovery period. **Methodology** Thirty adults participating in the 2024 Ogden Marathon were recruited. Blood samples were collected at three time points: (1) before the race

baseline, (2) immediately after finishing the race, and (3) 48 hours post-race. Plasma was analyzed using a Luminex® MAGPIX® immunoassay to quantify adiponectin (ng/mL) and insulin (pmol/L). A repeated measures ANOVA with least significant difference pairwise comparisons evaluated changes over time. Results Insulin levels decreased significantly from pre-race ($M = 81.14$ pmol/L) to immediately post-race ($M = 25.93$ pmol/L, $p < .001$) and remained lower at 48 hours ($M = 33.70$ pmol/L, $p < .001$ vs. pre-race), with no significant difference between post-race and 48-hour insulin ($p = .178$). Adiponectin did not significantly change immediately post-race ($M = 2368.48$ to 2847.77 ng/mL, $p = .093$), but increased significantly at 48 hours ($M = 4583.96$ ng/mL, $p < .001$). Conclusion Insulin decreased sharply after the marathon and remained low during recovery, while adiponectin increased later at 48 hours. This pattern suggests that marathon running induces a prolonged shift toward greater insulin sensitivity and enhanced lipid utilization during the post-exercise recovery period.

Abstract Name: Investigating Mechanistic Consequences of GSDMD Assembly at Mitochondria in Models of Alpha-Synucleinopathies

Parkinson's disease (PD) is a prevalent neurodegenerative disorder characterized by the accumulation of misfolded alpha-synuclein (α -syn) and chronic neuroinflammation. One pathway implicated in this neuroinflammatory response involves Gasdermin D (GSDMD), a key effector downstream of the NLRP3 inflammasome, which is cleaved upon activation and forms pores in the membrane that facilitate the release of inflammatory cytokines. In macrophages, cleaved GSDMD has been shown to localize to mitochondria, forming pores that lead to mitochondrial DNA release and activation of the cGAS/STING pathway. However, this mechanism has not yet been investigated in microglia, the brain's resident immune cells. This project aims to determine whether GSDMD contributes to mitochondrial dysfunction and neuroinflammation in microglia. To examine inflammasome activation, microglial cells from wild-type and Caspase-1 knockout mice have been treated with LPS and LPS combined with ATP at different time points. Western blotting was used to assess inflammasome activation by detecting markers such as NLRP3 and GSDMD. DNA leakage assays, including qPCR, were used to quantify cytosolic mitochondrial DNA. Moreover, to model PD-relevant conditions, primary microglial cells from wild-type and GSDMD knockout mice were treated with α -syn preformed fibrils. The hypothesis states that knocking out GSDMD will prevent pore formation in the mitochondria, thereby decreasing mitochondrial DNA leakage and activation of the cGAS/STING pathway. These findings would support a mechanistic link between GSDMD-mediated mitochondrial damage and neuroinflammation in PD. By clarifying GSDMD's role in microglial immune signaling, this project aims to address critical gaps in the understanding of PD pathogenesis and inform future therapeutic strategies targeting neuroinflammation in alpha-synucleinopathies.

Abstract Name: Placemaking Narratives in Food Halls

Today, in cities across the US, it is possible to walk into an old industrial building and order a fusion meal accompanied by entertainment, showcasing the gastronomy of urban restructuring. Using secondary data and literature review, we aim to explore how food halls rely on adaptive reuse and market themselves to contribute to developing contemporary cities. We created a database of all 360 operational food halls in the U.S and searched for patterns such as how many food halls serve immigrant foods, reside in reused spaces, and have small or local businesses under their roof. We then analyzed these characteristics to identify patterns in how food halls aim to integrate themselves into the urban fabric and cater to the experience economy, wherein memories outperform individual services. To better understand these patterns, we turned to the literature on food halls to examine how reusing buildings influences modern attitudes toward sustainable practices within architecture and food systems. By integrating the food halls database with existing literature, we found that food halls showcase changing consumer attitudes regarding land use and historical preservation. Food halls market themselves through ideals of sustainability, ethnic variety, and cultural significance, reflecting changes in urban redevelopment that demonstrate a consumer society valuing these ideals.

Abstract Name: Manganese induces oxidative RNA damage on R-loops of a long noncoding RNA in human cancer cells

Manganese (Mn^{2+}) is an essential trace metal for human life. However, a high level of exposure to Mn^{2+} can cause oxidative stress, DNA damage, and mutations, leading to neurodegenerative diseases and cancer. We have recently found that the gene transcription intermediate R-loops form hotspots of DNA and RNA damage. We further hypothesize that high level of Mn^{2+} can damage RNA and DNA on R-loops, thereby compromising RNA-guided DNA base damage repair. To test this hypothesis, we determined if a high level of Mn^{2+} can induce oxidative RNA damage on the R-loops of the long noncoding RNA gene MALAT1 in human kidney cancer cells without or with the deficiency of human translesion DNA polymerase pol η . The results showed that pol η gene knockout significantly increased the amount and frequency of RNA strand breaks and abasic sites on MALAT1 R-loops, indicating that pol η plays a crucial role in maintaining RNA integrity. We further demonstrated that 500 μM Mn^{2+} induced RNA base damage hotspots which are predominantly located on As and Us on MALAT1 R-loops. Our study provides the first evidence of Mn^{2+} -induced RNA damage on R-loops, opening a new avenue to reveal Mn^{2+} -induced genome instability in causing human neurodegenerative diseases and cancer via oxidative RNA damage.

Abstract Name: Understanding Student Thought Processes in General Chemistry and Introductory Physics

Introductory chemistry and physics are foundational to building students' knowledge and problem-solving skills that they will use throughout their time in college. However, students often struggle to apply their conceptual knowledge and mathematical skills to problems. As such, there appears to be a disconnect between what students know about content and how they solve problems. This project aims to help clarify this disconnect in knowledge and application. To do this, think aloud interviews were conducted with students where students worked through problems while explaining each step in their thought process. Questions were formulated from sources such as the Group Assessment of Logical Thinking, the Force Concept Inventory, and chemistry textbooks. Students were asked questions for both chemistry and physics topics, and introductory students and upper division students were both interviewed with the same set of questions. These interviews were then analyzed to determine the method that students think through the problem, specifically in terms of pattern recognition and proportional reasoning. These results will then hopefully be formulated into a plan that can be used by professors to adjust teaching strategies to increase student success. Future work will also aim to connect these results to common misconceptions that students have in these classes.

Abstract Name: SentimentVoice Korea

“SentimentVoice” is an ongoing series of immersive work exploring emotions and immigrant voices across cultures. The original project presents stories in the U.S. context, while “SentimentVoice Korea” adapts the concept to marriage migrant women in Korea and their experiences, expanding the dialogue through a different cultural lens. We want to focus on how emotions that technology fails to capture—complex, contradictory, and lingering outside of language—are marginalized. Interviewees reconstruct the emotional shifts they have experienced within Korean society in their own words, offering testimonies of how culturally specific emotional codes—such as *han* and *jeong*—have been received and internalized in their lives. These narratives move beyond individual stories to function as an emotional lens, revealing how Korean society constructs and maintains “othered emotions.”

Abstract Name: Using NADH-phasor FLIM to Monitor Changes in Mitochondrial Metabolism of Squamous Cell Carcinoma Cultured in Atmospheric and Hypoxic Environments and Differing HER2 Expression Levels

Squamous cell carcinoma (SCC) is an aggressive form of skin cancer and is among the most commonly treated cancers in the United States, with millions of patients being treated for SCC annually. While highly effective, current methods of diagnosing SCC are invasive and cannot monitor long-term changes in cellular metabolism. Our group investigated the use of an all-optical non-invasive method to simultaneously monitor changes in cellular metabolism and collagen in the extracellular matrix. To assess metabolic changes, we measured the levels of free and protein-bound NADH in cancerous cells using Phasor Fluorescence Lifetime Imaging Microscopy (FLIM). Critically, our group investigated changes in the metabolism of cells grown at atmospheric and hypoxic O₂ levels, as many cancerous tumors proliferate in hypoxic environments. Metabolism of SCC grown at atmospheric and hypoxic O₂ levels was investigated in conditions with and without glucose, and in the presence of electron transport chain (ETC) uncoupling and inhibition. We found that cells grown in hypoxic conditions shift from aerobic to anaerobic metabolism and rely less on the ETC. Our group was also interested in the expression of HER2 in SCC cells, a protein responsible for cell cycle regulation that is often overactive in cancerous cells. We quantified relative HER2 expression of cells grown at low and high O₂ and measured mitochondrial metabolism via NADH-phasor FLIM in the presence or absence of the HER2 inhibitor AG825. We found in SCC that the fraction of protein-bound NADH was higher in the absence of glucose, decreased in the presence of ETC inhibitors, and decreased when cells were exposed to AG825. We can conclude that NADH-phasor FLIM is an effective way to detect SCC based on changes in cellular mitochondrial metabolism.

Abstract Name: Automated Post-Disaster Building Damage Assessment Using Drone Imagery and Deep Learning

Natural disasters such as hurricanes, tornadoes, and earthquakes can cause widespread structural damage, posing immediate safety hazards, and complicating recovery efforts. Timely and accurate damage assessment is critical for guiding emergency response, allocating resources, and planning reconstruction. However, traditional assessment methods often rely on manual inspections, which can be slow, labor-intensive, and potentially dangerous for inspectors operating in unstable environments. This project aims to develop an automated system for post-disaster building damage assessment using aerial imagery collected by drone combined with advanced deep learning techniques. The system will be capable of processing high-resolution images to identify and categorize damage levels rapidly and consistently, enabling faster and more informed decision-making for emergency managers and government agencies. Data was collected using drones equipped with high resolution cameras that have captured aerial imagery of buildings in post disaster environments. These images will be hand segmented to classify the different types of structural damage (e.g, no damage, minor damage, major damage, destroyed). A state-of-the-art deep learning model will then be trained to recognize and classify the verifying degrees of structural damage. The trained models will be incorporated into a prototype application that can automatically process drone imagery and generate visual and numerical damage reports. The system will be evaluated using datasets and, where possible, real-world disaster imagery. By automating the building damage assessment process, this project has the potential to significantly reduce the time required to assess disaster impacts, minimize risks to human inspectors, and improve the overall effectiveness of disaster response. Beyond emergency management, the technology could also be applied to routine infrastructure monitoring and resilience planning, making it a valuable contribution to the fields of civil engineering, computer vision, and disaster management.

Lou O'Neil

Authors:

Abstract Name: Wear Is Your Hunger?

I aim to explore the line between animal and human in terms of emotional expression, value, and personal relationships. My argument is that we are animals at heart; it is not us vs them but instead we. I would like to have three models that each represent a different animal and slowly they fall into madness, fear, shame and go against each other instead of the common enemy- the hunter. The hunter is played by the camera, you never see this character, you only experience the scenes through their 'eyes'. The five final images will each depict an emotion along the journey of being hunted. Starting with docile transitioning into fear as the subject starts to become aware of the hunter, madness as the subject cannot find the source of their fear and starts to turn on its brethren/self, violence against the self as the madness sets in, and the finale is shame. The shots will alternate between far away shots and close ups. Docile- far, fear- close, madness- far, violence- close, shame- far. To complete my vision for the preliminary shoot, I worked with my model who is a dancer to determine

the body language that would convey each emotion best. Through my knowledge of photography and art, defining space, color use, and lighting, and her knowledge of dance, conveying emotions to an audience and body movement, I was able to articulate the concepts I had worked hard to put into words. This shoot was successful at seeing how audiences would perceive the work and figuring out how to better the images for the final shoot. For this shoot I only was able to use one model but plan to extend the shoot with other models, props, and lighting.

Abstract Name: The Intimacy of an Overcrowded Table

Though a dinner table is an inanimate object, it is too a place for individuals to come together to become a collective. Conversation flows around the table, alliances form and deconstruct as topics change, but there is a group mindset of being together in this place at this time, to listen and tell all at once. It can become a saving grace, a foundation of comfort, an atmosphere of home. I grew up having very individual relationships with my parents and not an encompassing family dynamic. This changed when I started being included in family dinners at my partner's house. At first, I felt uncomfortable with the idea of being trapped at a table with a group of people I felt I did not belong too. But every time I was told 'there is always enough room for you'. The sculpture is multimedia, a mix of woodwork, plaster, and 3D printing. The choice of the piece being primarily white is to convey the idea that these items are inanimate and do not hold the life and promise that the figures who would sit around these objects would. The mirror paper is to take place of shadow that the base of the piece resides on, which creates the shape of a house. The table, cutlery, and chairs are 3D printed to create a uniform and lifeless feel. The red thread symbolizes the conversation flow around the table as well as the connection binding them together. The table is merely an item, a tool, that can be utilized by people if they so choose. The people (absent intentionally in the piece) are what create the life; their conversations and jokes, anger and sorrow, these are what bring life. Through this sculpture I found my artistic voice. a

Abstract Name: Ukrainian Resistance in the Face of Russification: Nestor Makhno and Anarchism

In 1917, the Russian state saw great political change as the communist Bolshevik party replaced the traditional monarchy. The ensuing Civil War, which lasted from 1918 to 1922, saw the Bolsheviks attempt to gain control over the territories that made up the former Russian empire. Their efforts towards the incorporation and assimilation of other non-Russians is known as "Russification." The Bolsheviks faced numerous opponents and resistance movements, including the Makhno movement, or Makhnovshchina, that emerged in Ukraine in 1917. This research is on Nestor Makhno, the prominent leader of the Makhnovshchina. Makhnovshchina was a major Ukrainian anarchist movement that combatted Soviet oppression and Bolshevik rule at the turn of the twentieth century. Makhno used anarcho-communist principles to resist—both actively and passively—Soviet attempts to control the Ukrainian territory and suppress Ukrainian culture. Besides violence, the movement's focus on Ukrainian literacy and education,

anarchist ideology, peasant desires for political and economic autonomy, and the dissemination of anti-Bolshevik literature served as forms of resistance against Bolshevik Russification. This research examines the complex impact of Russification policies in Ukraine, contributing to a better understanding of how Soviet policies functioned and how Soviet authorities dealt with the local Ukrainian population. A study of the Makhnovshchina is especially significant today, as there is a destructive war currently unfolding between Russia and Ukraine that features a similar assimilation policy from the current Russian government as the one used by the Soviets toward Ukraine from 1917-1921. This analysis uses primary accounts derived from members, associates, and witnesses of the Makhnovshchina, such as Peter Arshinov's History of the Makhnovist Movement and several leaflets produced by the Makhnovists. This work also uses secondary sources that discuss other aspects of the movement, such as its exceptional use of violence and the peculiarity of its political ideology.

Abstract Name: Gendered Perceptions of Gene Editing: A Survey of Public Comfort with Somatic vs. Germline Gene Editing

The modernization of medical science has led to innovative biomedical procedures addressing persistent health conditions. With the introduction of CRISPR technology, gene editing has become possible; however, its implementation has led to controversy. To better understand the public's perception of gene editing, I distributed an 18-question survey through REP Data, receiving 417 total responses. Analysis of the results revealed clear gender differences in comfort levels toward various gene-editing applications. Males were more likely to endorse germline¹ editing for serious disease prevention (45.4% male vs. 31.0% female), a difference found to be statistically significant at the 0.01% level. In contrast, females demonstrated substantially higher uncertainty toward germline interventions (25.2% female vs. 6.3% male), suggesting heightened ethical caution surrounding genetic modifications passed to future generations. However, this hesitancy diminishes when the focus shifts to somatic² gene editing. A majority of female respondents (51.9%) supported somatic editing for serious disease prevention, indicating greater acceptance when genetic modifications affect only the treated individual rather than offspring. These patterns suggest that female reservations toward germline editing may be shaped by deeper associations with maternal identity and nurturing roles, reinforcing concerns about protecting potential children and maintaining natural developmental processes. This gender divergence highlights the importance of understanding how ethical perspectives informed by social and biological roles influence public acceptance of emerging biotechnologies. 1: Inheritable changes to the DNA of reproductive cells where traits continue through successive generations. 2: Non-inheritable changes to the DNA of reproductive cells.

Abstract Name: "Therapy is Not For Us": Understanding Community and Self-Imposed Stigma on Mental

Health Help-Seeking Behaviors in Black University Students

In the U.S., research has shown that mental illness prevalence is rising among youth. While mental health awareness has also increased, both acceptance and severity of symptoms are not uniform among demographics. For example, previous literature shows that black populations tend to have more disabling symptoms, yet are less likely to utilize mental health care. The main objective of this qualitative study is to understand factors that impede and facilitate mental health help-seeking behavior in black ethnic groups. A supplemental goal is understanding the nuances among ethnic groups and genders regarding MHHS. We intend to meet these goals by answering the following questions: 1. What factors do black individuals consider when seeking formal and informal help? 2. When black individuals have positive attitudes towards mental health help-seeking, what are some reasons they still don't seek help? 3. Through the lens of the Theory of Planned Behavior (TPB), what common themes contribute to lower perceived behavioral control (i.e., confidence in one's ability to change a situation through actions) in black, U.S.-based university students? 4. What effect does living in a predominantly non-black community (PNBC) have on mental health help-seeking behaviors in black adults? Data was collected through an online survey. Results were analyzed using thematic analysis and interpreted through the TPB. Most participants stated that an unbiased support source (45.7%) and stigma surrounding mental health (30.5%) were factors when considering MHHS. For those who said they would not seek help, self-reliance, being uncomfortable with sharing personal issues, and prayer were common reasons. Lack of financial resources, perceived inefficacy of counseling, and reliance on parental/community approval were common themes that contributed to lower perceived behavioral control. Most participants (36.2%) felt uncomfortable seeking help in a PNBC due to fears of dismissal and discrimination.

Abstract Name: Death By Beauty: Aesthetic Desire in Flaubert and Süsskind

This essay compares Gustave Flaubert's *Madame Bovary* and Patrick Süskind's *Perfume* to show how obsessive desire for beauty, when pursued for the purpose of possession leads not to revelation, but to moral ruin. Though Emma Bovary and Jean-Baptiste Grenouille differ in temperament, Emma is driven by romantic conceptions of beauty and Grenouille by detached aesthetic obsession, both characters treat beauty as an absolute and only, rather than one element of a balanced human life. Emma's longing to possess the romanticism of the novels she reads blinds her to reality, turning her romantic and spiritual yearnings and capacity for aesthetic experience into self-destruction. Grenouille's pursuit of olfactory perfection dehumanizes others while reducing beauty to an object that can be possessed and used to manipulate others. Both characters demonstrate how aesthetic desire for possession or embodiment, when uncoupled from morality and the lived world, becomes fatally misplaced. Their deaths, suicide, and ecstatic dismemberment respectively reflect each other as tragic culminations of aesthetic obsession. Through these dual downfalls Flaubert and Süskind criticize the traditional link between beauty and goodness, demonstrating that the unchecked pursuit of the sublime, or at least the attempt to own it, leads not to enlightenment, but to moral decay and death.

Abstract Name: Examining the Representation in Children's Media of Hearing Aids and the Connection to Positive Self-Image

About 20% of children ages 12 and under experience some degree of hearing loss (Boston Hospital). Causes of children's hearing loss can be attributed to otitis media, congenital factors, certain illnesses, and more (ASHA). Hearing aids, devices fitted in or behind the ear which amplify sound, can be prescribed for children with hearing loss as one of multiple options (NIH). However, research shows that the majority of individuals who would benefit from hearing aids do not use one, which can be attributed to many different factors (NIH). Though hearing aids are not the only option for children with hearing loss, they are an important consideration for those who are recommended these devices, as early use of hearing aids can help facilitate crucial communication and social development skills (ASHA). However, not all children show eagerness to wear hearing aids, and some may even reject them. This research will study children's attitudes towards hearing aids, the representation of hearing aids in media, toys, and books, and how to promote children's positive-self image with hearing aid use. These results will help educate how to promote positive perception of hearing aids for all children and increase the comfortability of children with hearing loss in receiving these devices. This research will also be implemented into Camp Hearo, an aural rehabilitation camp for children focused around positive representation.

Abstract Name: Robust Group PCA for Separable Noise: An Argument for Subject-Level PCA With Whitening

Functional magnetic resonance imaging (fMRI) indirectly captures neural function with high spatial resolution and has driven discoveries in brain connectivity across age, gender, and developmental stages. As fMRI datasets grow, loss of subject-specific details can bias group estimates, limit replication, and exclude minorities. Group principal component analysis (PCA) is the de facto tool to aggregate individual data, but it varies across implementations. Tools like FSL and GIFT support group PCA (gPCA) and have shaped neuroimaging studies for decades. Yet, the impact of subject variability on group results remains unquantified. This study aims to identify optimal approaches for group dimensionality reduction while preserving the ground-truth mean information. Three GPCA implementations are considered: 1) simple concatenation, 2) concatenation with variance normalization, and 3) concatenation with subject-level PCA whitening. We manipulate three key parameters: 1) the proportion of total variance assigned to signal sources, 2) the variance profile, which determines the subjects emphasized at the group level, and 3) subject rank, which accounts for subjects with differing component manifold projections. We also study two types of additive noise: a simple case where noise is orthogonal to the signal, and a hard case where noise is not orthogonal to signal, and we investigate the threshold for variability retained during subject-level PCA whitening. Our results show that the ground-truth mean captures variability poorly for highly dissimilar sources across subjects, revealing that even the idealized ground-truth mean can bias inferences about atypical subjects. Additionally, in the hard noise case, there is no prevailing method; however, in the simple noise case, only subject-level PCA with whitening and no data reduction uniformly outperformed all other approaches relative to the ground-truth mean performance and preliminary results show increasing the number of subjects improves gPCA approximation. Future work will explore rank sensitive approaches to establish final recommendations for neuroimaging analyses.

Abstract Name: How Virtual Reality Can Be Used to Further Our Understanding of the Urbino Studiolo

The Renaissance studiolo, Italian for study, or office, proves itself to be much more than a simple room with a desk. The studiolo in Urbino, Italy, once the office of the great humanist Federico da Montefeltro, and an excellent case study into the history of studioli, is one of the most celebrated examples from the Renaissance. The private chamber is lined with elaborate wooden inlay panels called intarsia and portraits of the great thinkers of antiquity. In addition to being used as a private study for the duke, it served as a display of Montefeltro's identity and values. By inspecting the space, we can gain insight into the duke's character, habits, and relationships. The original function of the studiolo has been somewhat obscured over time, especially since the palace was converted into a museum. To better understand and experience the studiolo as it once was, virtual reality (VR) will be used to recreate its historical context and significance within art history. Using the Urbino studiolo as a case study, my research aims to demonstrate how immersive technologies like VR change the way we analyze and experience historic spaces. To address this question, LiDAR scanning, photogrammetry, and 3D modeling have been used to create a high-resolution VR reconstruction of the Urbino studiolo. This model allows users to inhabit the space virtually, replicating the scale, atmosphere, and perspective encountered by its original visitors. By bridging Renaissance art history with VR technology within the field of digital humanities, this project demonstrates and concludes how immersive methods can enhance scholarship, enrich teaching, and make cultural heritage accessible to broader audiences.

Abstract Name: Denominational Influences on Christian Nationalist Beliefs

Christian nationalism has gained increasing attention as a cultural and political framework that blends national identity with personal religious dogma, and traditional, conservative belief systems. This study investigates the relationship between Christian church denominations, and the likelihood of endorsing Christian nationalist systems of belief. Using a quantitative survey design, participants completed the six-item Cambridge Christian Nationalism Scale, which measures the degree to which individuals support the fusion of Christianity with American civic life and the role of religion and God in political and public spaces. Responses were analyzed to assess variations in Christian nationalism scores across denominational categories, including Baptist, Nondenominational, evangelical Protestant, mainline Protestant, Catholic, and other Christian traditions. Preliminary analysis indicates meaningful denominational differences in the endorsement of Christian nationalist beliefs, with some groups exhibiting significantly higher alignment with Christian nationalist ideology and others showing more center to left leaning ideologies. These findings contribute to a deeper understanding of how religious affiliation shapes sociopolitical attitudes and highlight the importance of denominational context in discussions of religion and national identity.

Abstract Name: AI Adoption and Its Perceived Impact on College Education

Artificial intelligence is the fastest-growing technological field of the 21st century, and is influencing how we work, learn, and communicate. With its rapid integration across various industries, questions arise on its impact on the education system. The purpose of this research is to examine Americans' views on AI tool adoption and its impact on a college education. Furthermore, I am interested to test if these views vary by both age and level of education. To this end, I designed a 15 question survey and collected 447 responses using RepData. The results revealed that younger individuals use AI tools more often, compared to those aged 65 or older. Among education levels, those with some college and higher levels of education believe AI will bring more change to the college education system, compared to those with a high school education or less. These differences not only highlight pronounced generational and educational divides, but also raise critical questions about the future of the job market and the role of higher education. Younger and more educated individuals, who frequently use AI, are poised to benefit in a job market where AI competencies are increasingly essential. In contrast, lower adoption rates among older and less educated groups point to a growing risk of workforce displacement. The strong belief among college-educated respondents that AI will reshape education further suggests that academic institutions must adapt their curricula. Without integrating AI literacy, colleges risk failing to prepare students for a labor market already being transformed by AI.

Abstract Name: Exploring the Antimicrobial and Biofilm Activities of Common Food Dyes

Synthetic dyes are widely used in the food industry to enhance the visual appeal of processed products, yet their interactions with microorganisms remain underexplored. While some dyes are biodegradable, azo dyes in particular can persist in wastewater and soil, leading to ecological consequences that threaten soil quality and aquatic ecosystems. This study evaluated the effects of commonly used synthetic food dyes, red, blue, and green, on microbial growth and biofilm formation using 96-well plate assays against multiple bacterial strains and one fungal strain. Red dye had little effect on the growth of most tested microorganisms, though it slightly inhibited *Staphylococcus aureus*. It also promoted biofilm formation in *S. aureus*, *Enterococcus faecalis*, and *Staphylococcus epidermidis*. Blue dye enhanced growth in several Gram-negative bacteria and in *Candida albicans*, although overall growth was minimal. In contrast, green dye consistently inhibited microbial growth, with most activity observed against *Streptococcus oralis*, *E. faecalis*, *Listeria monocytogenes*, and *S. aureus* at different concentrations. These findings highlight the diverse and sometimes opposing effects of synthetic food dyes on microbial physiology, which emphasize the importance of further research into their implications for human and environmental health.

Abstract Name: Enhancing Student Success in APA 7th Edition: A Data-Driven Video Project for Social Work Education By Ruby Ortiz-Lopez

This Honors research project analyzes survey results identifying the most common areas where students struggle with APA 7th edition formatting and creates an instructional video offering step-by-step tips to improve their skills. Understanding and addressing these challenges helps students produce more professional, credible academic work and reduces formatting-related stress. Descriptive statistics such as frequencies and percentages will be used to identify the top survey responses and trends among students APA formatting challenges. Preliminary results included five qualitative responses from student participants. Other results indicated 76% reported being taught APA 7 in college. The majority feel confident in basic APA tasks like cover pages (28), title pages (28), and page formatting (24). However, students reported struggling most with annotated bibliographies (24), block quotes (23), and abstracts (18). Confidence levels were highest for title pages (53% extremely confident) and lowest for block quotes and annotated bibliographies. Despite challenges, 47% of students expect to graduate. Suggestions for improvement were limited, but some students expressed they are still learning or unsure how to improve. Most students have been taught APA 7, but significant gaps remain in applying complex formatting elements like annotated bibliographies, block quotes, and abstracts. Confidence is highest in basic elements like title pages and cover pages, but lowest in advanced formatting, suggesting uneven skill development. Graduate students and seniors made up the majority of participants, indicating that APA struggles persist even at higher levels of education. Student feedback was limited but indicated a willingness to learn and a need for clearer resources or ongoing support. The survey highlights the need for targeted educational support to build APA competence, especially in advanced writing skills. Findings are relevant to social work education by emphasizing the role of academic writing in preparing students for professional communication and documentation.

Abstract Name: Assessing Communication Between Social Service Agencies and Rural Communities

This study aims to assess how communication methods impact residents' awareness and utilization of services provided by social service agencies in rural communities. Participants were recruited through the collaboration with Meals on Wheels, flyers, email communication, phone calls, and snowball sampling. A local social service agency assisted in the distribution of recruitment flyers to clients. Additional participants were identified through the distribution of flyers in local community spaces, including clinics, churches, and community centers. The purpose of the study is to assess the perception of communication between social agencies and clients in rural communities, identify existing obstacles, and evaluate the impact of communication on awareness and utilization of local services. The results inform effective communication with their social services. This indicates that participants had rated the Likert scale as "very effective" with their social services in their rural community (68%;n=17). Participants who received less services, felt more confident in knowing where to locate social service agencies. Also, participants who reported receiving more resources have higher confidence levels than person who has less resources. The student researcher ran a sample of goodness of fit to determine if there was a difference in the highest level of education completed

among participants. Results indicated there was a statistically significance in education level among participants ($\chi^2(5)=11.72; p<.05; p=.039$). The knowledge obtained from this study is important as it will provide alternative perspectives on how social service agencies can better engage with rural populations, particularly in terms of outreach, communication strategies, and client involvement. The results inform policy decisions, improve service delivery models, and enhance the overall effectiveness of social service programs in rural settings. This research contributes to a broader understanding of challenges and opportunities in rural service delivery, benefiting not only the participants but also the wider community.

Abstract Name: From “Me” to “We”: Reimagining Vocation as a Shared and Inclusive Journey Through Student Co-Researcher Experiences

This project seeks to explore emerging insights from a community-based participatory research project embedded within Augustana Leaders in Vocational Exploration (ALIVE), a year-long program that invites sophomores to engage in sustained reflection on vocation, purpose, and belonging. Now in its fifth year, ALIVE has increasingly emphasized the relational and communal dimensions of vocational exploration. Responding to broader calls to move beyond individualized understandings of calling, this project examines how students and mentors navigate questions of meaning and contribution through shared practices of reflection, dialogue, and creative expression. Working alongside three student co-researchers - who simultaneously participate in ALIVE - we collaboratively designed the research questions, collected qualitative data through reflective journals, group conversations, participatory workshops, and creative artifacts, and engaged in group interpretation of the findings. Early results reveal how shared storytelling, intentional vulnerability, and creative engagement cultivate a deep sense of belonging and reshape participants' understanding of vocation from a solitary, self-directed quest into a collective, interdependent journey. In addition to presenting our initial research findings, we will reflect on our dual experiences as both ALIVE participants and co-researchers. This dual positionality offers a unique perspective into how collaborative inquiry supports personal growth while strengthening community connections. By drawing on our lived experiences, navigating uncertainty, building trust within a cohort, and engaging in communal meaning-making we aim to illustrate how ALIVE's model fosters purpose development through relationship-centred practices. Ultimately, this presentation highlights what ALIVE's evolving approach to vocational exploration reveals about nurturing purpose, belonging, and agency within a liberal arts context. Our hope is to contribute to ongoing conversations about how participatory, community-engaged models can expand vocational education to be more inclusive, relational, and responsive to the diverse experiences of students today.

Abstract Name: Parenting Stress and Couple Intimacy in Families of Autistic and Neurotypical Children

The current study examines whether parent gender, socioeconomic status (SES), and autism context moderate the relationship between parenting stress and couple intimacy. I hypothesized that parenting stress will be more strongly associated with lower intimacy in (1) families with autistic children compared to neurotypical children; (2) families with a lower SES compared to families with a higher SES; and (3) mothers compared to fathers. This is a secondary data analysis of data collected from 344 cohabiting couples, including both autistic and neurotypical children (aged 5–12 years; Hartley, Papp, & Bolt, 2017). Household income ranged from under \$40,000 to \$140,000+. The Personal Assessment of Intimacy in Relationships measure (Schaefer, et al., 1981) assessed relationship intimacy, and the Parenting Stress measure (Zarit et al., 1980) assessed parenting stress. Stress was negatively related to all types of intimacy for both mothers and fathers (all p values $< .01$), although the negative correlation between stress and intimacy did not differ between mothers and fathers. Stress and intimacy were also more strongly related in families of autistic children (r ranged from $-.12$ to $-.35$, all $ps < .01$) than in neurotypical families (r ranged from $-.08$ to $-.21$ and were not all significant). Finally, the association between stress and intimacy was non-significant in low-income families (\$40,000 or less), but significant in all other income brackets. These findings suggest that while there is a relationship between stress and intimacy in all families, there is a stronger negative correlation between stress and intimacy within families raising an autistic child, and within families with a higher SES, as opposed to families with a lower SES. These findings can help bolster further research surrounding stress-related interventions that could lead to more positive outcomes, such as increased intimacy and closeness within the parental relationship.

Abstract Name: Examining the Impact of the COVID-19 Pandemic on Hospitalists' Work Well-Being and Desire to Practice Medicine

Background: The COVID-19 pandemic had profound effects on healthcare, particularly on hospitalists (physicians who specialize in the care of hospitalized patients). Hospitalists were exposed to high stress and heavy workloads during the pandemic, which may have influenced work well-being and desire to practice medicine. Because hospitalists have higher turnover than other specialties, understanding these impacts is critical to addressing burnout and retaining providers. Therefore, changes in hospitalists' work well-being and desire to practice medicine were examined before, during, and after the COVID-19 pandemic. **Methods:** Anonymous surveys were administered at three time points: 2019 (pre-COVID-19), 2021 (during COVID-19), and 2024 (post-COVID-19). Surveys were sent to hospitalists at a community hospital in a Washington, DC, suburb. Desire to practice medicine was assessed on a 0-4 scale (0=regret becoming a doctor, 4=very strong desire). Work well-being was measured with the Work Well-Being Scale, which consisted of five questions each using a 7-point Likert scale. ANOVAs investigated the changes over time on the hospitalists' desire to practice medicine and work well-being. Statistical significance was set at $p < 0.05$. **Results:** There were 45 participants pre-COVID-19 (42.2% female), 38 participants during COVID-19 (52.6% female), and 45 participants post-COVID (48.9% female). Work well-being statistically significantly changed ($p < 0.007$) over time, specifically it was lowest during COVID-19 (25.1 ± 7.4), but similar before COVID-19 (30.3 ± 7.8) and after COVID-19 (29.4 ± 7.3). Hospitalists' desire to practice medicine was not statistically significantly different over time ($p = 0.26$). **Conclusion:** Hospitalists experienced a decline in work well-being during COVID-19, yet desire to practice medicine remained stable. This divergence suggests that despite reduced work well-being, potentially due to inadequate staffing, long hours, and moral distress, their sense of

professional purpose may have been strengthened. Future research should examine factors that may sustain a desire to practice medicine independent of work well-being.

Abstract Name: Developing a Grounded Theory of (Ex)Cannabis Users' Health Talk in Reddit Communities

Reddit has become one of the fastest-growing social media platforms with roughly 52 million active users daily. This platform allows people to create anonymous profiles where they interact with others or remain lurkers. Studies have found that social media platforms offer meaningful spaces for informal health communication and can empower individuals in their health decision-making. Studies have also looked at online health communication surrounding cannabis use and cessation, due to the widespread legalization and liberalization of cannabis. This research aims to understand the process of health communication online via the Reddit platform amongst (ex)cannabis users. The data were collected from four cannabis-focused subreddits (i.e., r/petioles, r/leaves, r/weed, and r/trees). This study used a netnographic approach and analyzed the data with constructivist grounded theory, moving through initial, focused, and theoretical coding. In total, 2532 original posts and comments were collected, and the current preliminary data analysis includes 628 coded posts. The data sheds light on the process and content sharing that exists in online cannabis spaces on Reddit. Specifically, people with faceless online profiles engage with one another from different cannabis use positions: (1) as current users, (2) as users who are interested in quitting or reducing use, or (3) as ex-users who have quit or moderated use. Within these online spaces (ex, users utilize Reddit as a channel for sharing and relating their experiences of cannabis-related health outcomes across mental, social, and physical well-being dimensions, as a source of supportive community (e.g., encouraging cannabis use goals), and for consulting with one another about harm reduction/abstinence strategies. Previous studies have also found that Reddit is used for discussing cannabis experiences and health information. However, researchers also warn of the risks of misinformation in these spaces. These findings can inform cannabis health education and expand knowledge about digital health literacy.

Abstract Name: Biophysical Investigations Into the Structure and Function of Pa and Bt Nitric oxide sensing Proteins

Nitric oxide sensing Proteins (NosPs) have been studied as important signaling molecules in various organisms. Particularly in *Pseudomonas aeruginosa*, NosP plays a role in heme binding and controlling the phosphorylation of NosP's associated histidine kinase, NahK. Recently, heme binding has been of particular

interest and how this is associated with the signaling pathways in bacterial biofilm formation. Computational structural characterization of *Pseudomonas aeruginosa* NosP predicts that heme binding occurs between the tri-symmetrical base and disordered cap regions. The cap is believed to open and secure the heme in position. Despite these predictions, the role of NosP's cap remains poorly uncharacterized. As a result, it was hypothesized that generating a NosP construct without the cap ($\Delta 208-301$) will diminish kinase inhibition and heme binding during in vivo and in vitro testing. To test this, capless, tagless, NosP was generated and purified, and the apo, ferric, and ferrous complex ligation states were assessed with UV-Vis spectroscopy. The inhibitory potential of these complexes with NahK was tested using HPLC analysis. The phenotypes downstream of NahK, such as the production of pyocyanin and swarming motility, were checked to see if the cap affects the ability of it to inhibit NahK. Interestingly, the in vivo data shows strong phenotypic evidence of the capless NosP exhibiting tighter inhibition, while the preliminary investigation into the capless mutant's heme binding properties show altered mechanics and reduced inhibition in vitro. Therefore, future work is needed to further understand how the heme binding plays a role in kinase inhibition.

Abstract Name: The Privatization of Black History

My project rhetorically analyzes the presentation of African American history in two slave plantations in South Carolina: McLeod and Boone Hall. Researchers have written about the presentation of African American history in public and private plantations, evaluating their sensitivity, correctness, and effectiveness. Most concluded that both public and private plantations have a long way to go, citing the language and speeches of the administrations. However, there is little focus on plantations in South Carolina, which was the port of entry for the transatlantic slave trade, and few dissect the rhetoric of the plaques used across the plantations. Additionally, due to the new governmental efforts to defund public parks and censor American history, there have been few academic articles written about the effects of such regulations. My presentation focuses on the representations of African American enslaved history in plantations, comparing the information presented in Boone Hall, a private plantation, and McLeod, a county-owned park. During my time at these plantations, I found that both plantations censor their language to cater to a white-majority audience. This could especially be seen at Boone Hall, where the history was inaccurate, incomplete, and often romanticized the lives of planters and their relationships with the enslaved. In contrast, McLeod's presentation of slave history was more accurate and revolved around the experience of enslaved African Americans. Based on these findings, I argue that public parks have made an overall more concerted effort to properly represent and preserve the history of African Americans, but the current government administration's regulations will further censor the presentations of such history. I argue so by analyzing the rhetoric of the plaques presented at various public and private plantations, their websites, and event advertisements, tying those rhetorical analyses to governmental funding cuts, content reviews, and regulations.

Abstract Name: Does the Hemoglobin Level in Daphnia Affect Their Phototactic Response to Predator Cues?

Nutrient pollution and climate warming interact to promote intensified seasonal hypoxia in lakes by causing larger phytoplankton blooms and organic matter deposition in deep water, and stronger thermal stratification, which inhibits mixing of oxygenated water into deeper depths. The crustacean zooplankton *Daphnia* are capable of producing hemoglobin (Hb), which enables them to better scavenge dissolved oxygen and improves their ability to survive under hypoxic conditions. However, the trade-off is that expression of reddish Hb makes *Daphnia* more conspicuous and more vulnerable to predation by visually-oriented predators (e.g., fish). *Daphnia* typically perform diel vertical migrations (DVM) in which they migrate to deep water during the day to avoid visual predators, and ascend to the surface at night for grazing and to experience warmer waters. *Daphnia* are known to assess their predation risks and to modify their response to light (phototaxis) and DVM behavior by detecting chemical cues passively released from predators (kairomones). This study examined the relationship between Hb level in *Daphnia* and their phototactic response to media infused with kairomones from visual predators (fish), non-visual predators (larvae of *Chaoborus*, the phantom midge), and control media (no predator cues). *Daphnia* obtained from two Minnesota lakes were sorted based on Hb level and used in laboratory phototactic assays. Consistent with expectations, we found that high Hb *Daphnia* were significantly more negatively phototactic than were low-Hb *Daphnia* in the presence of fish kairomones, and that *Daphnia* were less negatively phototactic in response to kairomones from a non-visual predator (*Chaoborus*, the phantom midge). These results suggest that *Daphnia* are capable of optimally tuning their phototactic response and DVM behavior in response to the type of predation risks that they are experiencing and their own Hb level. Future research will expand the number of populations examined to assess how generalizable these findings are.

Abstract Name: Effects of an 11-Week High Functional Resistance Training Program on Indices of Arterial Stiffness

Arterial stiffness is a systemic loss of elastic properties that significantly augment cardiovascular disease risk in adults. Investigations into specific behaviors and practices that influence arterial stiffness has been a priority in the past few years. Chronic aerobic and anaerobic exercise activity has consistently shown to attenuate or not influence markers of arterial stiffness in adults with chronic disease and otherwise healthy adults. Chronic high functional resistance training's effect on vascular compliance is less understood.

PURPOSE: To determine the effects of a chronic high functional resistance training program on pulse wave velocity and beta-stiffness index. **METHODS:** Participants (18-40 years old) were placed in a non-randomized fashion into high functional resistance training (HFRT) group ($n = 9$; ≥ 6 months of CrossFit experience; 4 female), or control (CON) group ($n = 8$; ≤ 6 months of exercise experience; 6 female).

Participants in the HFRT group trained at the same local facility 4-5 days a week, utilizing the same training program. CON group refrained from exercise during the study period. Body composition, 1,000 meter rowing test, deadlift 1 repetition maximum (1 RM), hemodynamic assessments and vascular compliance was assessed at baseline and follow-up. Repeated measures analysis of variance was used to examine within and between interactions on indices of arterial stiffness. **RESULTS:** There were baseline differences between groups in deadlift 1 RM (72.3 ± 18.2 kg mean difference (MD), $p < 0.01$), rowing time (143.8 ± 35.7 sec MD,

$p < 0.01$), and rowing average watts (153.8 ± 34.6 watts MD, $p < 0.01$). Following the intervention, seated diastolic blood pressure (DBP) increased only in the CON group (3 ± 4 mmHg MD, $p = 0.04$). No significant within and between group interactions were found in arterial stiffness variables. CONCLUSIONS: The findings indicate indices of arterial stiffness are not influenced by participation in chronic high functional resistance training

Abstract Name: 3D Printed and Phase Casted Bioabsorbable Interlocked Nail System for Segmental Bone Defect

This study was to evaluate bioabsorbable polycaprolactone–hydroxyapatite (PCL-HA) scaffolds and an intramedullary nail system for repairing critical-sized segmental long bone defects. The study utilized biocompatible and biodegradable materials—phase-cast PCL and PCL-HA—to fabricate scaffolds, nails, and screws for potential use in load-sharing fixation. There were three primary objectives: (1) fabricate porous PCL-HA scaffolds and an intramedullary nail system suitable for stabilizing a large tibial defect using polymer casting methods, (2) develop a custom targeting jig using stereolithography (SLA) printing to enable accurate delivery and fixation of the implant system within a goat tibia model, and (3) assess mechanical performance, biodegradation behavior, and BMSC compatibility of PCL and PCL-HA materials. The resulting bioabsorbable scaffold demonstrated cancellous-bone–range compressive strength, enhanced water absorption, and favorable degradation behavior. The targeting jig enabled accurate placement of the intramedullary nail and scaffold ex vivo, though screw strength remains an engineering challenge. Finite element analysis further showed reduced bone stress and acceptable deformation of PCL-HA components compared to titanium hardware. Ongoing in vivo evaluation aims to optimize mechanical stability while supporting osteogenesis using BMSC-seeded PCL-HA scaffolds.

Abstract Name: When Work Comes Home: An Empirical Assessment of Remote Work and Urban Travel Behavior

This research examines how the rise of remote work is reshaping urban transportation demand across major U.S. metropolitan areas. As telework becomes more prevalent, especially following the COVID-19 pandemic, cities are experiencing notable shifts in commuting patterns, yet the magnitude and drivers of these changes remain insufficiently understood. Using panel data from 2018 to 2024, this study integrates information from the Bureau of Transportation Statistics, the Federal Highway Administration, and the American Community Survey to analyze how changes in the share of remote workers relate to vehicle miles traveled (VMT) and public transit ridership. The dataset includes additional controls—such as local gas prices, employment rates, and population density—to better isolate the effects of remote work on mobility outcomes. A fixed-effects regression approach is used to account for time-invariant differences across metropolitan areas, enabling the study to assess how within-city changes in remote work adoption correspond with shifts in transportation demand over time. Preliminary results indicate that increases in remote work are associated with lower

commuting intensity, decreased peak- hour traffic, and notable changes in transit ridership patterns, with variations observed across regions and industry structures. These early findings contribute to a broader understanding of evolving post-pandemic mobility trends and offer relevant insights for planners and policymakers seeking to design sustainable transportation systems, allocate infrastructure investments, and adapt transit services to new patterns of urban activity.

Abstract Name: Social Media's Influence on Teens' Perception of Romantic Relationships

Social media is a powerful force that influences how teenagers view relationships. Apps like Instagram, Snapchat, and TikTok often show couples in a setting that may be perceived as perfect. They are always going on dates, happy, and posting pictures to show their emotional connection. Posting these things gives the viewer the idea that a typical relationship should always be fun, romantic, and easy. Because of this, many teenagers strive to be the same when it comes to their relationships. When their relationships don't match the relationship standards, teenagers may feel disappointed in the relationship they're in. Expectations may not be met, resulting in arguments that may lead to stressed or fractured relationships. Social media may also provide incidents where toxicity and jealousy occur, which may be viewed as normal. This may cause a wall between a healthy environment and an unhealthy environment. This proposed research study poses the following central research question: Does social media's portrayal of romantic relationships influence teenagers' expectations of real-life relationships? Semi-structured interviews will be conducted in order to solicit feedback regarding what teenagers view and understand about online relationship representation. Even more, this study will explore how social media's portrayal of romantic relationships influences teenagers' expectations of real-life relationships through an approach designed to capture teenage perspectives. By engaging in-depth questions that go beyond surface-level observations, this research will uncover the ways social media shapes relationship expectations during developmental years. By exploring this question, this study joins a broader conversation about digital media's impact on relationship development, but distinguishes itself through its specific focus on experiences, platform-specific content analysis, and qualitative methodology designed to capture emotional nuance.

Abstract Name: Personal Ambition is Found to be the Primary Driver of Academic Competition in South Asian Magnet School Students

Academic competitiveness among high school students is shaped by cultural, social, and familial factors. This study investigates the various drivers of academic competition among South Asian students at Woodbridge Academy Magnet School, with a focus on parental involvement, generational status, and cultural ties to India. Using a comparative study-based design, students rated their level of academic competitiveness on a scale from 0 to 10 and responded to questions regarding their backgrounds and environments. Quantitative data

were analyzed using bar graphs and a one-way ANOVA to find patterns and relationships between academic competitiveness and the different factors that could potentially influence it. The initial ANOVA, which compared competitiveness across the different drivers, yielded a p-value less than 0.05, indicating a statistically significant difference among groups. However, the rest of the results, in relation to generational status, frequency of visiting the country of origin, and parental involvement, all resulted in insignificant values. These findings suggest that while variability in competitiveness exists within the sample, the measured cultural and familial factors do not independently account for these differences. Instead, the complexity of student motivation may be more strongly influenced by internal characteristics such as personal ambition and individual personality traits. Further research should be conducted using a mixed-method approach, adding qualitative components such as interviews or focus groups to better capture the motivations and experiences that shape academic competitiveness among South Asian high school students.

Abstract Name: Investigation of novel capecitabine derivatives as colorectal cancer therapeutics targeting HT-29 cells

Capecitabine (CAP (pentyl side chain) is a widely used oral chemotherapy drug for cancer patients, recognized for its three-step metabolism into the commonly employed chemotherapy agent, 5-fluorouracil (5-FU). Mouse carboxylesterase 2 (mCES2) and human carboxylesterase 2 (CES2) perform a de-esterification step in the conversion of prodrugs, converting the drug into the active 5-FU component, which is hypothesized to be 60 times faster than the previously targeted carboxylesterase 1 (CES1). On the basis of enhancing the speed of the first step of CAP metabolism, CES2 would be targeted; however, due to the lack of availability of a defined protein structure of CES2, mCES2 was used to hypothesize modification of the ester side chain, thereby affecting CAP's overall delivery speed. The binding affinities of a structurally modified CAP were computationally measured in ICM Molsoft. The hexyl CAP derivative displayed an average higher docking score in mCES2 than the original CAP when in the tested pocket. Computational toxicity data was collected using ProTox3 and SwissADME, in conjunction with binding affinity, and analyzed to identify differences between the derivatives. The hexyl derivative showed a promising result with a stronger binding affinity than the control CAP. Further testing via QSAR indicates a potential benefit for a proposed hexyl derivative, with a decreased predicted IC₅₀ when compared to the control CAP. The hexyl derivative's potential as an improved alternative to the pentyl group is also supported by remaining within toxicity constraints while displaying an increased binding affinity in comparison to the original pentyl group.

Abstract Name: Assessing the Role of HSF in Regulating Aging

(Background) Heat shock factor (HSF) is a highly conserved transcriptional regulator in eukaryotes that activates the transcription of heat shock proteins essential for maintaining proteostasis during cellular stress. Thus, HSF coordinates chaperone networks to ensure proper protein folding and promote recovery from proteotoxic damage. Because age-associated decline in proteostasis is a hallmark of aging, HSF has been proposed to influence lifespan. However, the specific contribution of HSF activity to aging remains insufficiently understood. (Aim/Purpose) This study aims to determine whether alterations in HSF function affect longevity. Specifically, we sought to compare the chronological lifespan (CLS) of yeast expressing wild-type (WT) HSF versus mutant variants to assess whether HSF mutations extend lifespan or compromise survival relative to WT. (Approach/Methodology) CLS was measured using the DNY248 yeast strain, which requires exogenous HSF for viability. HSF WT and mutant alleles were expressed from His-marked plasmids, and 5-FOA counterselection was used to eliminate the URA3-based HSF plasmid. Following counterselection, single colonies containing HSF WT and mutant HSF were isolated and used to perform CLS assays. (Results) Preliminary data indicate that yeast expressing mutant HSF displays a significantly extended chronological lifespan compared to cells expressing WT HSF. This suggests that alterations in HSF function can influence long-term cellular survival. (Conclusions) These results support the idea that HSF contributes not only to acute stress responses but also to the regulation of aging. The identified mutation appears to enhance the activity of HSF, potentially improving proteostasis and thereby extending chronological lifespan relative to WT. These findings provide valuable insight into how modulating HSF may serve as a strategy to promote longevity.

Abstract Name: W7 as a Therapeutic Modulator of Sarcomeric Dysfunction in a Hypertrophic Cardiomyopathy Model, R92W-cTnT

Hypertrophic cardiomyopathy (HCM) is a heritable cardiac disorder marked by hypercontractility, myofibrillar disarray, and increased risk of sudden cardiac death in young adults. Hypertrophic cardiomyopathy (HCM) is a disease of the heart muscle characterized by thickening of the left ventricular and impaired relaxation of the heart. Mutations in the cardiac thin filament proteins have been linked to the development of HCM. An HCM-linked mutation in cardiac troponin T (cTnT), Arginine-92-to-Tryptophan (R92W), has been shown to increase myofilament calcium sensitivity contributing to altered systolic and diastolic function. Current treatments for HCM are limited and to date only one FDA-approved drug, Camzyos, targets mutation-specific mechanisms, proving the need for precision therapeutics. Previous groups identified a calcium desensitizer W7, a small-molecule inhibitor that binds to TnC and alters cTnI-cTnC interactions and decreases calcium-induced activation of the thin filament. We hypothesize that calcium desensitization in R92W myofibrils via W7 intervention can reduce ATPase activity. To explore this, we isolated cardiac myofibrils from transgenic mouse models expressing the R92W mutation and conducted NADH-coupled ATPase assays under physiological calcium concentrations to assess functional contractile parameters. Our results demonstrate that W7 decreases sarcomere ATPase activity in R92W-mutant myofibrils. Future studies will investigate other mutations in the same cTnT residue, R92L, R92Q and the effects of W7 on ATPase activity. Additionally, we will be titrating different calcium concentrations to generate a curve of calcium vs ATPase activity to look at the effects of W7 on myofibril activation.

Abstract Name: Language, Education, and Receipt of Therapy Services for Autism

Behavior therapies for autism help children to learn skills and adapt to new situations, but for families with limited levels of English proficiency and education, healthcare is difficult to access. Differential stigmatization of autism in certain communities may additionally affect parents' use of autism services for their children. This analysis focused on disparities in behavior therapy use for autistic children by primary household language (PHHL) (English vs. Spanish vs. other language) and parent education level (less than high school vs. high school or equivalent vs. more than high school) using 2022-2023 National Survey of Children's Health data. The sample included 4,612 children currently with autism ages 3-17 years. RStudio was used to compute descriptive statistics and a fit logistic regression model examining associations of PHHL and parent education with behavior therapy use. The model was adjusted for sex, age, race, household income, and insurance type. PHHL was not significantly associated with behavior therapy (Spanish: 95% CI [0.83, 3.26]; other language: 95% CI [0.41, 2.71]). Parent education level was significantly associated with behavior therapy use: parents with less than a high school education had 65% lower adjusted odds of behavior therapy use than parents with a completed high school education or equivalent (95% CI [0.18, 0.69]). The lack of data on households speaking non-English languages (n=290) in this sample may limit study findings. Measures to improve public health knowledge of non-English speakers in the U.S. could include comprehensive anonymity of responses, translation of surveying documents into languages other than English and Spanish, and consideration for low literacy levels more generally. Significant associations of parent education and behavior therapy use highlight the importance of referral, care coordination, and other supports to help parents with lower education levels access autism services for their children.

Abstract Name: An Evaluation of Automated and Machine Learning Tracking Systems in Characterizing Negative Geotaxis in Zebrafish (*Danio rerio*)

Zebrafish (*Danio rerio*) serve as a prominent model in behavioral neuroscience, particularly for evaluating

stress and anxiety-like responses (e.g. negative geotaxis). The present study investigated negative geotaxis in adult zebrafish responding visually to mixed sex shoals in an adjacent tank. Subjects' responses were assessed using a 3-Chamber Open Tank Free Swim Task (3-COTFST) in which the subject swam freely in a central tank flanked by two stimulus tanks, each flanking tank contained either an alarmed or unalarmed shoal. Subjects had visual exposure to small shoals ($n = 4$) in each of the flanking tanks. One shoal is unalarmed while the alarmed shoal is exposed to 1.5 nM, 3.0 nM, or 5.0 nM concentrations of H_3NO . Digital videos were processed using EthoVision XT, a proprietary motion-tracking application, and DeepLabCut, an open-source machine-learning tool. Both platforms reliably quantified anti-predation responding, demonstrating a strong correlation between applications for spatial metrics such as cumulative duration in zone while other metrics had weaker, but still significant, correlations. Data from the Ethovision analysis provided significant main effects for condition and zone, confirming increased freezing and bottom dwelling at higher concentrations. Data from the DeepLabCut analysis offered superior resolution regarding individual variability, revealing specific Condition by Sex interactions for distance moved that were less distinct in standard tracking. While EthoVision provides a standardized, accessible platform ideal for reproducible group-level comparisons (quantal approach), DeepLabCut allows for flexible, fine-scale characterization of complex behavioral patterns (graded approach). These findings suggest researchers should select tracking software based on the specific need for rapid screening versus detailed analysis.

Abstract Name: Financial Education Channels, Capability and Well-being: A Validated Survey Instrument

Approximately two-thirds of US citizens are financially unhealthy (Financial Health Pulse, 2024). This number is anticipated to be higher with ALICE (Asset Limited, Income Constrained, yet Employed) families in Hawai'i. Mainstream individual-centric financial education does not resonate with the host culture of Hawai'i where family and communal cultures are strongly valued. This study presents a validated, culturally appropriate survey instrument investigating various channels of financial education and its association with individual financial capabilities and definitions of financial well-being. Previous research shows a positive relationship between financial education and improved financial knowledge, attitudes, and practices (KAP), however less is known about how other channels of financial education, such as family socialization, may influence financial behaviors, financial well-being, and financial priorities. Our draft survey, based on existing literature, included measures of financial KAP, financial educational channels (including formal, such as direct schooling, and informal educational channels, such as via family and friends), self-reported financial well-being, socioeconomic status, and demographics. We use the Family Dinner Index (FDI), a measuring tool rating the time and quality of family mealtime interactions, as an indicator for family financial socialization. The survey will allow us to study how financial education channels influence individuals' definitions of well-being and how family contexts, particularly through the FDI, shape financial KAP. Our survey, which will be finalized through expertise review involving 40 scholars and cultural practitioners in the field, will be administered to adult and college student participants in Hawai'i during Fall 2026. Results of this study will offer insight for policymakers and practitioners on the proper financial education channels, contents, and best approaches for Hawaii and beyond.

Abstract Name: Investigating the Functions of DRP1 Splice Variants in the Brain and Skeletal Muscle

Mitochondria play a crucial role in cellular functions ranging from energy production to cell death. As such, maintaining mitochondrial health is essential. Mitochondrial health is dictated by a balance of two opposing forces: fission and fusion. Dynamin-related protein 1 (DRP1) is the key driver of fission, and DRP1 expression and activation changes have been associated with various disease states, including diseases of the brain and skeletal muscle, both tissues with high metabolic demand heavily reliant upon mitochondrial health. It is well known that DRP1 undergoes post-translational modification in the cell, but little research has investigated DRP1 splice variants. The Hempel Lab has previously demonstrated that certain DRP1 splice variants are differentially expressed in various tissues, with skeletal muscle and brain tissue expressing distinct splice variant profiles that differ from each other. Prior research has shown that exons 16 and 17 play a crucial role in DRP1 reliance on interaction with various fission adaptor proteins and the mitochondrial membrane. The question that remains, and what this project attempts to answer, is what interactions are favored by the different DRP1 splice variants in the brain versus skeletal muscle, and why? We have bred and maintained mice that uniquely express single DRP1 splice variants, the long variant, which contains both exons 16 and 17, and the short variant, which lacks exons 16 and 17. We then utilized these mice for skeletal muscle and brain harvests, which will be used for Western blots and co-immunoprecipitations to probe for various adaptor proteins used by DRP1 to facilitate fission. We expect that DRP1 variants will interact with/rely on different adaptor proteins. Specifically, we anticipate that the brain, which highly expresses the long variant, will rely on mitochondrial fission factor (MFF) more heavily when compared to the skeletal muscle, which highly expresses the short variant.

Abstract Name: Understanding Mosquitoes' Plant Choices: Chemical Attractions Underlying Mosquito Phytophagy

With an estimated billion people impacted by malaria, yellow fever, and zika every year, the mosquito was declared the "World's Deadliest Animal" by the CDC in 2024. Mosquitoes have an exquisite sense of smell, widely studied for its role in locating human hosts for blood meals. However, mosquitoes also use their olfactory systems to locate and assess sources of plant sugar— an essential food for longevity and fecundity. In fact, only female mosquitoes feed on human blood for egg maturation, whereas all mosquitoes rely on plant sugar as a source of energy. Despite plant sugar being an essential nutrient source, relatively little is known about the identity of plants preferred by mosquitoes for their sugar meals. Unlike prior studies, this research utilizes molecular techniques to uncover the mosquito plant diet as found directly within the mosquito gut. In my research, I use wild-caught *Aedes aegypti* and *Aedes albopictus* mosquitoes, or the vectors for yellow fever, zika, dengue, and chikungunya. I first extract the DNA from the mosquito's digestive tract, then conduct PCR to amplify plant-specific sequences. Following, I use DNA sequencing to identify the plant species consumed by mosquitoes based on barcoding markers. Each plant species possesses a unique bouquet of scent chemicals, which may influence mosquitoes' foraging behaviors. To further investigate the chemical profiles of mosquito-attractive plants, I analyze its volatile organic compounds (VOCs) using gas chromatography-mass spectrometry (GC-MS). With GC-MS, I separate the chemical compounds within a

plant's odor bouquet to identify as well as quantify its relative abundances. By linking chemical profiles to mosquitoes' feeding preferences, this research helps determine which plant volatiles attract mosquitoes, providing insights into how odor-based mosquito traps can be improved. This work contributes to a broader understanding of mosquito feeding ecology, with applications for global public health and mosquito population management.

Abstract Name: The Impact of Ongoing Violence on Street-Level Bureaucrat Peacebuilding in Colombia

Successful implementation of a peace agreement can alleviate enduring systemic cycles of poverty, violence, and instability, significantly improving the well-being of millions of people. However, countries that have undergone a peace agreement are often highly volatile, which makes bureaucratic action ineffective and causes the implementation of post-conflict public policy to fail. Scholarly works have examined the nature of bureaucrats' work in the field, as well as their motivations to commit to implementing a peace agreement. Nevertheless, the literature has overlooked a crucial factor that could impact bureaucrats' work and hinder peace agreement implementation: ongoing levels of violence that persist within regions, created by multiple third-party actors, even after the agreement has been signed. This paper studies the Colombian 2016 Peace Agreement between the Colombian government and the FARC guerrilla to answer the following question: Does the level of ongoing violence within a region hinder the peace agreement implementation by street-level bureaucrats? The question is answered via a theoretical framework that posits street-level bureaucrat motivation as the causal mechanism through which local levels of violence (operationalized by the number of homicides) lead to fewer peace agreement implementation projects. This relationship is measured using a cross-sectional time series observational study with quantitative data analysis across the 170 municipalities included in the Colombian Territorially Focused Development Programs (PDET) public policy. The expected finding is a negative causal relationship between violence and the number of implemented projects. This research will shed light on how local levels of violence can hinder nationwide bureaucratic peacebuilding efforts and how external factors can have an impact on the motivation of street-level bureaucrats.

Abstract Name: High Functioning: Understanding the Autistic Experience through Ceramic Tableware

Autistic people are often misunderstood for not being able to meet expectations without accommodations. Often, autistics look for strategies to get around such obstacles. Perhaps exposing an audience to ceramic objects that appear one way but function in a different way would be helpful in increasing understanding of the strategies that disabled people must use every day. The researcher designed uniquely functioning ceramic tableware to help the observer or user better empathize with the experience of autism. The researcher sought efficiency of design, ease of use, and something aesthetically pleasing whenever possible. Tableware pieces were designed and produced through wheel throwing, including cups, bowls, plates, jars, pitchers, and teapots. Each completed piece met one of the following criteria: looking non-functional but functioning in a

new way, looking like the average piece, e.g., a teapot, but functioning differently, a multi-functional piece, or exploring an unexpected property of the ceramic clay body, i.e., sound. The exhibition of the pieces will include two divided spaces. In the first space, observers will have a chance to interact with the pieces and think about their functions. In the second space, the audience will view the pieces as they were meant to function by seeing a video of people using the pieces during a party. The juxtaposition is meant to give viewers an insider glance at autism as an analogy to the ceramic hacks. In a world where individuals are valued for their functions, or what they produce that is valuable to others, pieces were designed to separate out the idea of the value of an object from its function. The hypothesis is that this analogy will be useful in helping viewers empathize with autistics' experience of being misunderstood.

Abstract Name: Tissue-Specific Differences in Genomic DNA Yield and Oxidative Damage in Mice

The efficiency of genomic DNA (gDNA) extraction can vary considerably among organ tissues due to differences in cell composition and metabolic activity. This study quantifies DNA yield and oxidative nucleoside content across multiple mouse tissues to evaluate tissue-dependent variations in extraction efficiency. Although tissue-specific variation in oxidative DNA damage has been previously studied, the combined influence of extraction efficiency and nucleoside recovery is still not well defined. This project addresses that gap by comparing multiple tissues under identical handling and processing conditions. Samples were collected from three adult mice, with each organ divided into three 20 mg aliquots, yielding nine replicates per tissue type. The organs examined included kidney, liver, heart (whole and partitioned), lung, brain, gastrointestinal tract (whole and partitioned), testis/ovaries, and esophagus. High-molecular-weight (HMW) gDNA was extracted using the Monarch HMW DNA Extraction Kit for Tissue (NEB T3060), and concentrations were determined by NanoDrop spectrophotometry. All tissue handling and extraction steps were performed under cold conditions with frequent ethanol decontamination to prevent degradation and contamination. DNA hydrolysis was conducted as an effective procedure, in which isolated nucleosides can be accurately measured for oxidatively generated DNA damage. DNA hydrolysates were analyzed by LC-MS/MS to quantify deoxyguanosine (dG) and 8-oxo-deoxyguanosine (8-oxo-dG) as markers of oxidatively generated DNA damage. It is hypothesized that tissues with higher metabolic rates, such as liver and heart, will yield greater total DNA amounts but also exhibit higher levels of oxidatively generated DNA damage. The results of this study will establish baseline tissue-specific DNA yields and oxidation information. These baseline measurements could guide future studies evaluating tissue-specific responses to antioxidant therapies or aging-related oxidative stress.

Abstract Name: Strength in Simplicity: Evaluating Adversarial Transferability in Quantized Lightweight CNNs

Deep learning (DL) models are central to many vision-based applications, from facial recognition and autonomous driving to environmental monitoring, and are often deployed on edge or IoT devices with limited computational and energy resources. This necessitates the use of lightweight DL architectures for efficient processing, which in turn introduces new trade-offs between model efficiency and security. Among these challenges, adversarial attacks pose a unique risk, as they can be applied to physical objects in the form of patches and remain effective across viewpoints and lighting conditions. These attacks are generated by using the gradients of a neural network's loss function with respect to the input image to identify small pixel changes that cause misclassification. Studies have shown that such gradient-based attacks can transfer between DL models, meaning that an attack designed to fool one vision system can also deceive others. Prior work suggests that attacks crafted for standard Convolutional Neural Networks (CNN) transfer poorly to algorithmic lightweight variants such as Dilated CNNs. However, the effect of these attacks on structure-based lightweight models obtained through pruning or quantization requires further investigation. In this study, we focus on generating adversarial attacks using both standard CNN models and lightweight variants obtained through pruning and quantization and we evaluate their transferability between these models. We train and test our approaches on two datasets: (1) a high-resolution animal image dataset and (2) the low-resolution Fashion-MNIST dataset, to capture differences across varying levels of visual detail. Based on preliminary experiments, we expect that attacks crafted for standard CNNs will be notably less effective against pruned and quantized models. The results of this research will advance the understanding of CNN defense capabilities and how these are affected by architectural and algorithmic modifications, to assist in developing more effective defense strategies.

Abstract Name: Identifying Metabolites and Their Functions Found in Native and Invasive *Phragmites australis*

Phragmites australis is found in both North America and Eurasia. The Eurasian subspecies became invasive to North America in the 1800's. Millions of dollars have been spent annually in efforts to remove these invasive plants. In order to understand the similarities and differences between native and invasive *P. australis*, we analyzed the metabolites found inside them. We performed Liquid Chromatography-Mass Spectrometry analysis of native and invasive plant roots collected from five sites in Minnesota. These metabolites were sorted based on their presence and abundance in native plants, invasive plants or both. In order to further quantitate how much of these metabolites are present, they were also sorted by a logarithmic abundance ratio of invasive/native. Those with a negative ratio were found in greater abundance in native plants and those with a positive ratio were found in greater abundance in invasive plants. If the abundance ratio was between (-1) and (1), that data was excluded from the analysis. A total of 1290 metabolites were identified between all of the samples and a total of 446 were sorted. 58 were found strictly in the native plants, 13 were found strictly in the invasive plants and the remaining 375 were found in both. After determining the quantity of the metabolites, qualitative analysis was performed by considering their biological, cellular and molecular functions. Taking a look at the functions of these metabolites allows for a better understanding of how each of these plants survive and react to biotic stressors like pathogens and predators as well as abiotic stressors like temperature, drought, salinity and oxidative stress. These results will determine which metabolites are responsible for the spread and resistance of invasive *P. australis* as well as the metabolites that allow the native *P. australis* to remain present and healthy in their habitats.

Abstract Name: Sculpting the Soundscape: Creating Refuge Spaces for Neurodivergent People

Loud honking, steady movement, constant chatter, and tumult. Cities are full of sound. For most people, this background noise fades away. Yet, for many neurodiverse individuals, these sounds can become overstimulating, exhausting, if not stifling. Clinical research has shown how a controlled environment can improve the neurodivergent experiences, especially when space filters sound in nuanced ways. However, such controlled spaces are not typically in reach in urban settings. How can we insert spaces for relief in urban life beyond clinical facilities? This design research explores the capacities of architectural interventions to create spaces for neurodivergent refuge. The challenge is that architecture is often approached as something to be seen and occupied. This research explores how we can intentionally sculpt sound to create restorative, yet sensory-inclusive retreats within urban environments. This work begins with the idea that sound can be designed. By using methods such as shaping geometries, surfaces, and natural buffers, architecture can turn noise into calm. This is achieved by diffusing, absorbing, reflecting, and reframing sound into a rhythm. This study focuses on how these spatial and acoustic strategies can help regulate sensory input, giving users a sense of calm, control, and grounding within the intensity of the city. This proposal develops a network of small, neuro-inclusive spaces that sit within the city while providing separation from it. In an effort to shift sound by creating transitions between intensity into quietness, techniques such as gravel paths, wood paths, water, and planted buffers will be used. This paper argues that architecture can act as an instrument for listening while also shaping how sound is perceived and felt. By reframing urban design through sound and sensory inclusion, this research imagines a city that doesn't just make room for quiet but essentially learns how to listen.

Abstract Name: Floor Bacteria Mitigation: An Integrated Approach using DBD Plasma Jet and an Autonomous Robot

A study by the LCSVA Medical Center found that hospital floors are major hotspots for bacteria. While traditional disinfectants are effective, they contain harsh chemicals that have a negative impact on the environment, and they often have harsh chemicals that pose environmental and occupational health risks. We hypothesize that an autonomous system utilizing a Dielectric Barrier Discharge (DBD) plasma jets can be used as eco-friendly methods to eliminate surface bacteria on hospital floors. To test this, a locally fabricated DBD plasma torch was made using a glass dielectric barrier with two electrodes to generate a helium plasma jet (~15–20 slpm, ~3–4 kV, 20–40 kHz), and characterized it by measuring input power (~10–15 W) and performing emission spectroscopy to identify active radicals. A key objective was to determine and maintain the optimal torch-to-surface distance for effective sterilization throughout the robot's operation. An automated robot equipped with the plasma torch was also developed to scan the floor, it utilizes 80 mm Mecanum

wheels for omnidirectional movement at 5 ft/s and four 12V DC 37D 6.25:1 metal-gear motors. The chassis was fabricated from 0.375-inch thick extruded acrylic to ensure rigidity and safely support the payload, which includes the plasma drivers for three plasma torches needed for complete floor coverage, along with custom mounts. The robot's control system is built around an ESP32-WROOM microcontroller which enables both manual control (via a Bluetooth controller) for functionality and maneuverability. The final presentation will detail the full engineering design methodology, as well as the plasma characterization process, the mechanical and control system implementation, and the comprehensive safety plan. It will also include ongoing results from *E. coli* mitigation experiments conducted under stationary and moving conditions.

Abstract Name: Rotational Spectroscopy of Carbon Dioxide Clusters for Green Solvent Development

Many solvents that are used for industrial and synthetic purposes have caused deterioration and toxicity in the environment. The purpose of this project is to determine whether a fluid form of carbon dioxide (supercritical CO₂) would be an effective, environmentally friendly solvent, making industrial chemistry greener. This can be answered by observing how different compounds interact with carbon dioxide. Specifically, identifying molecular clusters of different sizes helps reveal the orientations and positions of molecules as they interact. The initial aim was to identify a cluster of three difluoroethylene (C₂H₂F₂, DFE) molecules with one CO₂. Difluoroethylene is a small molecule that can interact strongly with a range of different solvents. In a microwave spectrometer, gas is sprayed into a vacuum, causing molecules to cool and cluster together. Each cluster absorbs different frequencies of microwave radiation, producing a series of lines called a spectrum. The lines act like a barcode, giving a unique pattern that provides insight into how these molecules interact with each other and their specific arrangements. Analysis focuses on identifying distinct patterns related to the structure of interest among thousands of possible lines in the spectrum. Analytical tools in Python help identify groups of lines that go together, revealing patterns of large clusters. The project method involved recording a microwave spectrum of a DFE and CO₂ mixture. A computational chemistry program was used to predict the most stable cluster arrangement. Predicted structures were then used to estimate what the spectroscopic patterns would look like. Expected results included a 3 DFE:1 CO₂ cluster, but observations were not consistent with that. Further analysis led to a hypothesis that the structure may be a 3:2 cluster. Observed results showed that as clusters increase in size, the carbon dioxide and DFE molecules arrange themselves in a contrasting way, compared to smaller clusters.

Abstract Name: Women's Participation in Anticommunism as a Benefit and Detriment

Though women played a significant role in shaping the domestic success of anticommunism during the 1950s, they are often left out of the historical discussion. By conducting original research on primary sources, I discovered that in fact, white middle and upper-class women propelled anticommunism, and that they did so

by relying on traditional, prescriptive gender ideals. At the same time, conservative women actually moved quite effectively into the public sphere, playing critical roles in politics and civic initiatives. Ultimately, conservative women set the stage for the emergence of the New Right. They did, however, ostracize and leave out progressive and liberal Black women, because they believed that racial equality was connected to communist ideology. Many fighting for civil rights had to limit their political participation out of fear of being accused of communism and even attacked. In contrast to white women, Black anticommunist women were motivated by their dislike of how the Communist Party adopted a patronizing approach to civil rights in order to draw in more members. Thus, conservative white and Black women at odds with each other. Further, working-class women differed from middle and upper-class women, especially those in unions, who advocated a more moderate stance. They supported the Communist Party's campaigns for greater social and labor benefits. Thus, by analyzing diverse women's different agendas in regard to anticommunist activity, we gain a more accurate understanding of women's vital role in shaping the national, postwar anticommunist movement.

Abstract Name: LIPA Inhibition Enhances the Therapeutic Efficacy of DNA-Damaging Agents in Ovarian Cancer Through Induction of ER Stress and Enhancing DNA Damage

Ovarian cancer (OCa) is the most lethal gynecologic malignancy in the United States, largely due to limited early detection and the development of chemoresistance following initial treatment. This highlights the need for improved therapeutic strategies. Recently, our team identified ERX-208, a novel molecule with strong activity against OCa cells. ERX-208 targets lysosomal acid lipase A (LIPA), inducing endoplasmic reticulum (ER) stress, disrupting protein synthesis, and promoting apoptosis. The objective of this study is to evaluate the potential of ERX-208 to enhance the efficacy of FDA-approved chemotherapeutics. We performed in vitro screening of 147 FDA-approved chemotherapy drugs in combination with ERX-208 to assess effects on OCa cell viability. Dose-response data were analyzed using SynergyFinder Plus. To validate synergistic effects, we conducted cell proliferation, colony formation, cell cycle, apoptosis, invasion, DNA damage, and comet assays. Preclinical studies using patient-derived organoids (PDO) and xenograft (PDX) models evaluated combination efficacy in clinically relevant systems. Drug-combination screening identified multiple synergistic pairs in OCa models. SynergyFinder analysis revealed strong sensitivity and synergy scores for several DNA-damaging agents. ERX-208 monotherapy inhibited OCa cell growth in vitro and in vivo, consistent with its induction of LIPA-dependent ER stress. Combination treatments with paclitaxel or cisplatin further amplified these effects, significantly reducing viability across OCa cell lines. Mechanistic studies showed enhanced gamma-H2AX accumulation, increased DNA damage, robust induction of ER stress markers, and reduced invasion following combination treatment. In PDO and PDX models, ERX-208 combined with DNA-damaging agents produced marked tumor suppression beyond monotherapies, confirming translational relevance. ERX-208 also reduced viability of therapy-resistant OCa models in vitro

and inhibited xenograft growth in vivo. These findings support ERX-208 as a potent ER stress-inducing agent that enhances the therapeutic efficacy of standard chemotherapies in OCa models. The patents surrounding ERX-208 are licensed to EтираRx.

Abstract Name: Starlink-Based Navigation System for Fixed-Wing UAV

Conventional UAV navigation and control systems rely on short-range RF communication, imposing significant limitations on operational range, real-time control capabilities, and autonomous mission execution. While existing research addresses regulatory frameworks, communication relay strategies, and UAV positioning optimization for extended-range operations, a comprehensive and cost-effective solution integrating satellite-based Internet connectivity with web-accessible control remains absent from the literature. This project presents a Starlink-based navigation and control system for fixed-wing UAVs, enabling real-time telemetry monitoring and command transmission through a web-based interface accessible globally from any Internet-connected device. By leveraging low-earth orbit satellite connectivity, the system overcomes the range constraints inherent to traditional RF approaches while providing operators with a flexible, customizable control environment. The proposed architecture addresses the critical gap between current commercial drone limitations and the demands of extended-range autonomous operations, offering a scalable framework for UAV missions beyond visual line of sight.

Abstract Name: The Opioid Epidemic in America: How Science, History, and Policy Collide in a Crisis Repeating Itself

The opioid epidemic in America is a multifaceted, complex crisis shaped by historical, scientific, and policy failures. This paper examines the origins of the nationwide public health emergency that is the misuse of opioid medications and their evolution, by tracing the effects of pharmaceutical marketing in the 1990s and the rise of synthetic opioids, such as heroin and fentanyl. Through using current research on the neurobiology/chemistry behind addiction, effective treatments, and harm reduction strategies, the paper addresses the epidemic in a scientific and political light. Particular attention is given to recent federal decisions that cut funding for naloxone distribution and training, bringing awareness to the severity of the issue.

Abstract Name: KLF6 Enhances Macrophage-Mediated Inflammation and Atherogenesis

A hallmark event in the development of atherosclerotic plaque is the accumulation of lipid-laden macrophages in the subendothelial layers of affected blood vessels. Macrophages are key players in all stages of atherogenesis, including plaque initiation, growth, and rupture, as well as healing of ruptured plaques. In this context, macrophages are the principal innate immune cells that modulate atherogenesis by engaging in various processes, such as inflammation, extracellular matrix degradation, phagocytosis, and efferocytosis. In the current study, Kruppel-like transcription factor 6 (KLF6) deficiency attenuated proinflammatory gene expression in macrophages and experimentally induced atherosclerotic plaque development. In vivo studies showed that myeloid-KLF6 deficiency on Apoe-null background significantly curtailed high-fat/high-cholesterol diet-induced atherosclerotic lesion formation and macrophage abundance in atherosclerotic plaques. Integrated transcriptomics and Gene Set Enrichment Analysis showed that KLF6 deficiency significantly curtailed a large number of tumor necrosis factor (TNF)-induced gene targets, TNF-induced interferon- γ response, interferon- α response, and inflammatory response signaling in macrophages. At the molecular level, KLF6 promoted interferon regulatory factor 1 (IRF1) signaling to enhance TNF-induced proinflammatory gene expression in macrophages. Collectively, study results show that KLF6 promoted proinflammatory gene expression in macrophages and enhanced experimentally induced atherosclerotic plaque formation in vivo.

Abstract Name: Acute Effects of the Nordic Hamstring Exercise on Hamstring Contractile Function

Between 2001 and 2022, athlete injuries and corresponding time away from competition and training doubled. This occurrence led to a focus on injury mitigation among coaches and athletic medical personnel. The Nordic hamstring exercise (NHE) is used to specifically target the hamstring function. The NHE is typically executed using a very controlled cadence. Recently, an NHE variant has gained interest. This version uses a free-fall eccentric phase and rapid concentric braking phase and is referred to in the literature as the fast NHE (NHEfast). Hamstring load and risk of injury peaks during the late swing phase of sprinting. Early research suggests that training with the NHEfast may better address this concern than traditional NHE. It has also been suggested that when the NHEfast is performed, the participant experiences less fatigue. The purpose of this study was to compare the acute effects of the NHE and NHEfast on hamstring function and fatigue. In a randomized crossover design, 12 varsity football athletes completed two conditions (NHE and NHEfast). Each condition consisted of 3 sets of 5 reps. Hamstring function was measured at pre-NHE and 24, 48, and 72 hours post-exercise. Isometric hamstring strength was measured at 0.52, 1.04, and 1.57 radians of knee flexion, and concentric hamstring strength and power was measured at 1.04 rad/s and 3.14 rad/s on a Biodex isokinetic dynamometer. A one-way ANOVA was performed for each isokinetic and isometric condition. The analysis revealed no significant differences ($P > .05$). While there appears to be no contractile force differences, this study still may provide coaches and athletes information that can be used to plan training.

Abstract Name: Student Success and Outcomes: An Analysis of Pell Eligible Students at Mason.

There are many questions around the various factors impacting student success in undergraduate studies. The following research study examined Pell Grant students at George Mason University to understand opportunities and potential barriers to student success. To do this, researchers conducted 18 focus groups with a total of 72 students ($N = 34$ Pell eligible students, $N = 38$ non-Pell eligible students). The goal of this research was to gather qualitative findings on current students' perspective on current events, college choice, belonging, academic experiences, work experience, success resources, and graduation preparation. Once data was collected, researchers conducted thematic analysis and coding to identify common themes and trends in responses across groups. Findings highlighted both general impacts and the differences between Pell and non-Pell eligible students. From the analysis, researchers discovered that Pell eligible students were more location-conscious and attempted to stay closer to home while in school. Furthermore, it was also discovered that Non-Pell eligible students were more interested in Mason based on its proximity to DC and that they

connected with faculty more based on research interests. Across both groups, researchers found that students connected more with faculty when they found them compassionate, many students had one to two jobs, and students utilized peers, family, and other existing relationships to seek help for college. The insights these findings provided serve as implications for overall student outcomes at universities.

Abstract Name: The Abdominal-B and broad transcription factors function in dsf-expressing neurons to regulate egg laying in mated *Drosophila melanogaster* females

Previously, the Shirangi lab identified a set of neurons in *Drosophila melanogaster* that co-express the genes, dissatisfaction (dsf) and doublesex (dsx). These neurons are localized to the abdominal ganglia (AG) of the ventral nerve cord (VNC) and have been named the DDAG neurons, for the dissatisfaction-doublesex abdominal ganglia. Previous results have shown that the DDAG neurons regulate sex-specific behaviors, such as mating and egg-laying. For my project, I investigated genes that initiate double-sex activation in DDAG cells. In previous research, we used a dsfGal-4 to drive a UAS-dsx-RNAi, which blunted dsx mRNA transcripts in dsf cells. When females of this genotype were tested in an egg-laying paradigm, they significantly decreased egg laying compared to their wild-type counterparts. Using data from a recent single-cell RNA sequencing experiment, we identified thirteen highly expressed genes in the DDAG population, which could potentially initiate dsx activation. Using an egg-laying paradigm, I tested each of these identified genes with a dsfGal-4 driver, to see if I could recapitulate the egg retention phenotype. Two genes, Abdominal-B (Abd-B) and broad (br), led to a statistically significant decrease in egg-laying. We hypothesizes that Abd-B and br contribute to dsx acquisition in dsf cells and the proper development of DDAG neurons.

Abstract Name: Advising, Mentorship, and Community: A Low-Cost Model for Engaging First generation NCUR Researchers

Undergraduate research is a nationally recognized high-impact practice that enhances academic achievement, cultivates a sense of belonging, and increases student retention and persistence. These benefits are amplified when students have access to positive mentorship, collaborative inquiry, and opportunities to disseminate their work through venues such as the National Conference on Undergraduate Research (NCUR). Yet first-generation and limited-income scholars (FGLI) continue to access these opportunities at disproportionately low rates. These gaps widen during lean grant years, when funding constraints limit paid research placements, conference travel, and capacity to mentor undergraduates. This proposal responds to these challenges by

strengthening and adapting undergraduate research infrastructure to evolving conditions, with an explicit emphasis on both inclusion and excellence. At UW-Madison, the Center for Educational Opportunity (CeO) and the Office of Experiential Learning (OEL) have developed a holistic and equitable support model that serves first-generation and Pell-eligible scholars, using proactive advising, inquiry-based curricula, and early-entry research opportunities. This presentation will examine the effectiveness of multilateral partnerships among academic departments, research labs, and student-support units, student organizations in expanding affordable research opportunities using quantitative and qualitative analyses. Ultimately, this research seeks to advance national efforts to build sustainable, equity-centered pathways that empower GLI students to become the next generation of researchers, problem-solvers, and collaborative leaders.

Abstract Name: Global Talent Flows and the U.S. Labor Market

The study analyzes how optional practical training (OPT) and STEM OPT programs in the United States function as structural mechanisms connecting international higher education and the U.S. labor market. Using SEVIS administrative data in 2024, the distribution of majors of more than 1.21 million international students and their participation in OPT/STEM OPT showed that 52% of international students majored in STEM and about 18% actually entered the U.S. labor market through OPT or STEM OPT. This shows that these programs are not just an extension of stay, but a key path responsible for the supply of high-skilled manpower in the U.S. According to previous studies, the 2008 STEM OPT extension policy significantly increased the selection rate and degree acquisition rate of STEM majors, and had a positive effect on maintaining high-skilled manpower in the U.S. In addition, the empirical evidence that about 40% of STEM OPT participants will later switch to H-1B visas shows that OPT is a major channel linking U.S. higher education and long-term employment. As a result of the comparative analysis, competing countries such as Canada, the U.K., and Australia have provided more predictable post-graduation routes and confirmed that the competition for global talent acquisition is intensifying. Overall, this study shows that OPT and STEM OPT play a key role in maintaining the US innovation economy by providing a pipeline of high-skilled personnel in engineering, computer engineering, and technology. These programs are not just student systems, but strategic policy tools that connect American universities and industries, increase productivity, and maintain the US advantage in global talent competition. Therefore, the stability and expansion of the OPT/STEM OPT path proves essential to maintaining long-term economic competitiveness in the United States.

Abstract Name: Evaluating the Effect of Prenatal Cannabinoid Exposure on Placental Lipid Transport and Accumulation

As more states legalize recreational and medicinal cannabis, rates of cannabis consumption have risen across most demographics, including pregnant women. However, population studies suggest a link between prenatal cannabinoid exposure (PCE) and altered metabolic health of offspring. As the placenta is a key mediator of fetal metabolism, we hypothesized that PCE alters placental metabolism. In this study, pregnant rats were exposed daily to vaporized Δ^9 -tetrahydrocannabinol (THC; 100 mg/mL) or polyethylene glycol 400 (PEG; vehicle control) from gestational days (GD) 5-18. On GD19, fetuses and placentas were collected. Both fetal and placental weights were significantly higher in the THC group ($p < 0.05$), suggesting metabolic alterations. We next isolated RNA from placentas and performed RNA-sequencing. The PCE placentas had over 1,100 differentially expressed genes ($\log_2\text{foldchange} > 1$, $\text{padj} < 0.05$). Downstream gene ontology analysis showed enrichment of pathways related to lipid catabolism and protein-lipid complex formation. To assess corresponding protein changes, we quantified markers of placental lipid transport and catabolism using Western blotting. We found that the apolipoprotein, ApoE, was significantly elevated in the THC-exposed placentas ($p < 0.05$). To determine if changes in gene and protein expression corresponded with increased lipid accumulation in the placenta, we visualized lipid deposition using Oil Red O staining. THC-exposed placentas exhibited increased lipid accumulation compared to the PEG control group. This study establishes a link between PCE and increased lipid catabolism, protein-lipid complex formation, and lipid accumulation in the placenta. Additionally, increased placental ApoE is correlated with preeclampsia and preterm birth, suggesting a much larger role for PCE in placental dysfunction and adverse pregnancy outcomes. Overall, this work supports a role for PCE in influencing placental lipid metabolism, with potential consequences for fetal metabolic programming.

Abstract Name: Who's Land Project

"Whose Land?" is a podcast and public dialogue project that explores the histories of farming, land and migration between New York and Wisconsin, with an emphasis on land loss and dispossession. Working in collaborative community-scholar-student teams, the project aims to frame discussions around how land practices affect Indigenous, Black, white and Latinx communities today. The goal is to raise consciousness around issues of spatial justice and the racial dimensions of social belonging, facilitating dialogue across the "rural-urban divide," and envisioning models of reconciliation. Our initial research phases have led to the development of a digital map identifying and telling stories of important sites of BIPOC history and dispossession in Milwaukee. This coming Spring we will continue this work, examining these sites in more depth, collecting land records, exploring the genealogies of historic residents, conducting oral history research, and connecting with past and current community organizations. Four regionally-based field teams are currently working on this project: New York City, Rural New York (Central New York Finger Lakes region), Milwaukee, and Rural Wisconsin (southwestern and central eastern portions of the state). UWM hosts the Milwaukee team, headed by Joe Walzer (Cultures & Communities).

Abstract Name: Antiestrogens present agonist activity in bone in the presence of osteoporosis resulting in a bone protective treatment option for estrogen receptor positive breast cancers

Breast cancer is one of the most significant causes of mortality among women and the second leading cause of cancer death in women. The estrogen receptor (ER) is a key oncogenic driver in the majority of breast cancer (BC). ER-positive BC is the most common molecular subtype of BC. Management of ER+ breast cancer varies depending on menopausal status. For premenopausal women, the goal is to suppress estradiol production from the ovaries with surgical oophorectomy and/or aromatase inhibitors. In postmenopausal women, endocrine therapy (ET) serves to suppress estradiol production from sources other than the ovaries. During the menopausal transition, estradiol levels decrease, resulting in a negative balance of the bone remodeling cycle, which can lead to osteoporosis. ET also leads to a decrease in estrogen and osteoporosis induced by ET in ER+ BC has become a concern. The purpose of this study is to identify ETs with context-dependent agonist/antagonist activity. In this study, ovariectomized NSG mice were treated with various antiestrogens over a 6-week period. Tamoxifen, Elacestrant, and Lasofoxifene were administered 5 times a week to the mice at doses of 50 mg/kg, 60 mg/kg, and 5 mg/kg (respectively). Fulvestrant was administered at 5 mg/dose once a week, and E2 was administered via a slow-release subcutaneous pellet. At the endpoint, sections of the femurs, tibias, and uterus were retrieved and interrogated by histology and histomorphometric analysis using micro-CT. From imaging, significant differences in bone density and trabecular thickness were observed between the E2 and treatment groups. Ongoing studies will utilize select models to determine agonist activity in bone, producing bone-protective effects from the antiestrogenic endocrine therapies. Data from this study will translate into novel ET treatment combinations that alleviate the osteoporotic effect induced by decreased estrogen from ET.

Abstract Name: Perspectives on Simulation in Spiritual Care Education

Simulation has been widely used in medical education for the purpose of creating a controlled, safe environment for students to encounter realistic situations and practice essential clinical skills. Spiritual care providers (SCPs), commonly referred to as chaplains, are allied health professionals who attend to the religious, spiritual, and existential needs of people in healthcare settings. Despite the salience of clinical training and graduate-level education, there has been little research regarding the role of simulation in SCPs' professional preparation. VCU's Department of Patient Counseling utilizes simulation within their education programs and is one of a very few in the country training SCPs with this pedagogical approach. To explore how SCPs describe their experiences using simulation in spiritual care education, we invited Patient Counseling alumni to participate in a focus group and share their perspectives on the role of simulation in their professional preparation. Our qualitative study has conducted 1 focus group and has a second scheduled with a total of 7 alums; our team is currently recruiting for 2 additional focus groups for January. The focus groups will gauge perspectives of both alumni who have experienced simulation and those who have not. From focus group transcripts, we will conduct an inductive thematic analysis. Our poster will present the

themes in the data and discuss whether or not we see SCPs experiencing similar benefits as reported in research for other clinical professionals. We will make recommendations from our results for further research and considerations for simulation in spiritual care education.

Abstract Name: How race-based courses influence racial identity and sense of belonging for Black students at a predominantly white institution (PWI).

Our project examines how race-based courses influence racial identity and sense of belonging for Black students at a predominantly white institution (PWI). Through a survey of 140 students 67 Black and 75 non-Black we analyzed differences in representation, campus experiences, and interest in race-based classes. The findings reveal a clear disparity: while non-Black students overwhelmingly report feeling represented and connected to the university community, many Black students describe feeling underrepresented, overlooked, or disconnected from the broader campus environment. This gap raises important questions about the university's stated commitment to diversity and the lived experiences of its students of color. We also explored students' willingness to enroll in race-based courses. Many non-Black students expressed limited interest, often viewing these classes as unrelated to their academic or personal goals. In contrast, Black students showed strong engagement and described meaningful benefits from taking such courses. When focusing specifically on Black students' responses, the data indicates that race-based classes offer valuable spaces for exploring identity, processing shared experiences, and building supportive peer networks. Students reported that these courses foster deeper critical thinking, self-reflection, and community formation skills and supports that extend far beyond the classroom. Overall, our research underscores the significance of race-based curricula as tools for promoting inclusivity and supporting students of color at PWIs. These courses provide academic and social spaces where Black students can feel seen, heard, and valued in ways that general coursework may not offer. By sharing these insights, we aim to spark broader conversations about campus climate, representation, and the importance of curricular offerings that reflect the diverse identities of the student body. Our project advocates for institutional efforts to expand race-based courses and to create a more inclusive and supportive environment for all students, particularly those from marginalized backgrounds.

Abstract Name: Generalized Jones Matrices and Their Application in Point Spread Function Imaging

A deep understanding of image formation in optical microscopes is crucial for analyzing images and for the development of new approaches to imaging. This specific research topic focuses on the point spread function (PSF). The PSF depicts the three-dimensional diffraction patterns of a point-like source. Optical images can be thought of as consisting of distributions of these point sources so the PSF directly affects the resolution

and quality of experimental images. While there already exists theoretical frameworks for the PSF such as the Debye-Wolf PSF theory, they do not account for the digital spatial light modulators (SLMs) used in microscopy with adaptive optics. PhD student Brenden Chasteen and Dr. Jörg Woehl are currently developing PSF theory further to account for SLMs which could potentially allow for more accurate simulations of modern imaging techniques using adaptive optics. In Debye-Wolf PSF theory, a point source can be depicted by propagating plane waves. In microscopy however, there will often be many optical instruments that will end up changing or adjusting the propagation, phase, and polarization of these plane waves. As a result, it is important to track these adjustments using Jones matrices. A Jones matrix initially tracks two cartesian components following the assumption that the direction of propagation of a plane wave after it travels through an optical instrument does not change. However, this assumption is not always the case so PSF theory requires the use of Generalized Jones matrices. These matrices include the tracking of a third component that accounts for changes in propagation direction which is more applicable to optical instruments. Generalized Jones matrices are a fundamental part of PSF theory and an understanding of how they can be used for optical instruments is crucial for further developing PSF theory to account for SLMs.

Abstract Name: Investigating Eye-Tracking and Genetic Biomarkers of Psychosis in Youth with Autism Spectrum Disorder

Individuals living with Autism Spectrum Disorder (ASD) are not the only group of patients who experience challenges with social relatedness and struggles with interpersonal relationships are associated with a range of disorders. While commonly associated with Autism Spectrum Disorder (ASD), these symptoms are also prevalent in individuals with psychosis. ASD and youths at-risk for subsequently developing psychotic disorders share unusual thought content, challenges with social interaction, and stereotyped behaviors. Due to the overlap in symptoms and experiences common to both disorders, misdiagnosis of ASD in youth displaying prodromal psychosis symptoms may be increased. This study aims to understand the association between eye-tracking deficits with individuals with ASD diagnoses, and their experience of psychotic symptoms.. This research study focuses on ASD and psychosis using two biomarkers, eye tracking and saliva, to identify which biomarkers are associated more with psychosis than with ASD. This could then be used to inform diagnostic tools used in differentiating ASD and prodromal psychosis in teenagers. This study recruits adolescents aged 13-17 with an ASD diagnosis. Data collection measures include saliva samples for genetic testing, a prodromal psychosis questionnaire asking about different experiences and how bothered the participant is by these experiences, the MATRICS Consensus Cognitive Battery (MCCB) which focuses on measuring cognitive functioning related to schizophrenia and other similar disorders, and lastly the smooth pursuit task which captures saccades using an eye-tracking camera. We will present an overview of the study design and preliminary data from the eye-tracking task.

Abstract Name: Sustainable Aviation Fuel's Effect on Fluorocarbon Viton O-rings

In response to the alarming rise in aviation-induced CO₂ emissions, the commercial aviation sector has accelerated development of sustainable aviation fuels (SAFs) to mitigate soot and contrail formation, issues largely attributed to the aromatic content in conventional Jet-A fuels. SAFs - biomass-derived alternatives - are currently limited to a 50% blending threshold with petroleum-based fuels to compensate for aromatic losses during the hydrogenation process, a critical factor for maintaining seal-swell characteristics and other key fuel properties, including dielectric constant. This study investigated the impact of Jet-A-HEFA-SPK fuel switching on fluorocarbon O-ring seal integrity, a material considered highly resistant to chemical degradation. Multiple Jet-A, HEFA-SPK, and HEFA-SPK blends of ARO150 simulated O-ring exposure in a legacy engine drop-in model, using extended transition bath soaks. Post-exposure analysis was conducted using Thermogravimetric Analysis (TGA) and Dynamic Mechanical Analysis (DMA). TGA results revealed minimal fluorocarbon O-rings fuel absorption compared to nitrile seals; however, significant derivative mass loss shifts were observed during fuel switching, indicating potential elastomer chemical alterations. DMA results demonstrated that while unexposed and Jet-A exposed O-rings maintained consistent mechanical properties, switching from Jet-A to HEFA-SPK led to significant Young's modulus changes, suggesting possible polymer backbone or cross-linking modifications. Ultimately, although fluorocarbon O-rings exhibit minimal swelling differences, fuel switching induces detectable material changes, which may impact long-term seal performance. Furthermore, increasing aromatic content to 12% in HEFA-SPK did not fully restore baseline mechanical properties, suggesting that the FAA-mandated 8% aromatic minimum may not entirely mitigate long-term material degradation risks.

Abstract Name: @DarkHumor: Race-Blindness, Racism, and Racialization in Mexican Digital Discourse

Racialization, the process through which one is marked and treated as a certain race, can be complex and contradictory. My project uses a contemporary case study of satirical political discourse on social media during the 2024 Mexican presidential elections to document the ways in which racialization is operationalized without the explicit naming of race. The ideology of *mestizaje*, which touts the development of an exceptional "raceless" race through centuries of racial mixture in Latin America, is a core component of the Mexican identity. However, racism remains a central facet of Mexico's landscape, perpetuating the erasure and subjugation of the Black, Indigenous, and Asian presence and experiences in the country's national identity. Despite claiming unity, *mestizaje* sustains the race-blind conditions needed to ignore, deny, and disavow racism in Mexico. The public nature of social media can provide important insights into the process of racialization by providing an accessible view of popular reactions to racism. Digital satirical environments are rife with racist language, made permissible under the guise of dark humor. The novelty of digital social

network research, coupled with the recency of the 2024 presidential elections, signal an opportunity to address understudied phenomena. I focus on a racist political post by popular Mexican meme account @EsDeMamador on X (previously Twitter) on the day of the election. I utilize an intersectional framework to analyze an array of 56 pre-selected (sub)replies to the original post. Drawing from literature on ethics in the digital humanities, Critical and Computer-Mediated Discourse Analysis, post-colonialism, and Critical Race Theory, I illuminate how non-racial categories (i.e., class, political party, religion) are weaponized as instruments of racialization. These reflect, refract, and advance exclusionary national imaginaries. My findings accentuate how white supremacy, anti-Blackness, and anti-Indigeneity continue to permeate daily interactions in Mexico today, despite the country's alignment with race-blind ideologies.

Abstract Name: Measuring Lunar Crater Depths Using Photometric Shadow Analysis

Measuring the depth of craters on the moon is important because it can tell us an abundance of information about the moon, such as the moon's age, history, and composition. This project's goal is to measure the depth of various craters on the moon accurately. To achieve this, a CPC 9.25-inch Schmidt-Cassegrain telescope will be used, along with an STL-11000M CCD camera, to capture images of the moon. Images are taken through the Astrophotography Tool software, and they are processed using AstroImageJ, an astronomical photometry software. Within this software, images are cleaned using dark frames, bias frames, and flat fields. Images will consist of monochrome as well as full color. Observations are made during the waning and waxing phases. This timing is chosen for two main reasons. The first being that the moon's high position in the sky reduces the distortions the atmosphere naturally causes when light tries to pass through it. Second, this is when the terminator – or the line that separates the dark side of the moon from the sunlit side – is most distinct, causing prominent shadows more straightforward to measure. Observations will also occur over multiple sessions to lessen uncertainty and ensure the most accurate data is obtained. Using the lengths of the shadows the craters cast and the angle from which the light is coming in, the depth of the crater can be determined. Comparison of calculated depths and published reference values will determine accuracy. This work illustrates the capabilities of small telescopes within the astronomy field and provides further insight into the characteristics of the moon.

Abstract Name: Elements in Transition: The Evolution of First-Year Student Experience from Pre- to Post-COVID-19

The college years are a critical period for identity exploration and the development of independence separate from one's familial unit (Arnett, 2000). The "college experience" (a collective of central themes functionally universal to American universities across varying executions) facilitates opportunities for students to develop these skills and undergo the transition into young adulthood (Arness, 2000). The COVID-19 pandemic radically altered how students engaged with the college experience. Students battled increased rates of depression, anxiety, and boredom, struggled to maintain their physical health, and felt disconnected from

family, friends, and peers (Birmingham et al., 2023). Our goal is to compare key metrics across three First Year Seminar (FYS) cohorts (Fall 2019, 2021, and 2023) to better understand how the COVID-19 pandemic impacted the college experience. The key metrics being compared were belonging, academic inquiry, and time management. There were a total of 385 undergraduates who completed a comprehensive survey on a variety of topics related to the first year experience including involvement on campus, wellbeing, and assistance and the FYS course such as beneficial experiences and feedback for instructors and peer mentors. Due to the categorical nature of the data, chi-square analyses were employed. Results suggest that students' sense of belonging decreased during the pandemic ($p < .001$), which is further supported by the finding that less students joined clubs during that time ($p = .02$). Findings also indicate that students worked less during the pandemic ($p < .001$). Additionally, results showed that students studied less ($p = .04$) and attended tutoring less during COVID-19 ($p < .001$). Taken together, these outcomes demonstrate a pattern that the first-year student experience was negatively affected by the pandemic. This knowledge gained can be used to alter the first year experience in meaningful ways to meet current students where they are in this post-COVID-19 landscape.

Abstract Name: Bridging the Gap: Empowering Vulnerable Populations Through Cosmetic Surgery for Genetic Malformities

Researchers dedicated to advancing science and health critically examine the risks and benefits of craniofacial surgery. Current literature emphasizes reconstructive surgery's potential to enhance psychological well-being and social inclusion for marginalized individuals. While these procedures carry inherent risks, their positive psychosocial outcomes—particularly in boosting self-esteem—are crucial for those facing stigma. The National Institutes of Health has identified psychosocial factors influencing decisions about reconstructive surgery across diverse sociodemographic groups, revealing barriers to timely treatment for craniofacial conditions. Reconstructive surgery is often misconceived as purely elective; however, for individuals with conditions like cleft lip and palate, these procedures are essential medical interventions that restore both physical function and dignity, fostering social integration. This research seeks to answer: “How do reconstructive surgery interventions for individuals with cleft lip and palate empower marginalized populations and enhance their well-being?” By examining the effects of these surgeries on individuals facing systemic healthcare barriers, we contribute to promoting health equity. This study employs a systematic review of published case series in the Journal of Universal Surgery focused on congenital abnormalities, analyzing secondary data on patient satisfaction and outcomes. Preliminary findings indicate significant improvements in speech, facial symmetry, self-esteem, and social integration. This research underscores the urgent need for outreach and educational initiatives in underserved areas, highlighting healthcare providers' roles in facilitating access to transformative interventions, thus empowering all individuals to receive the care they need and deserve.

Abstract Name: Evaluating the Efficacy of Food Recovery Network

In 2019, the United States Environmental Protection Agency estimated that 66 million tons of food waste was generated in the food retail, food service, and residential sectors. That same year, the United States Department of Agriculture estimated that 35.2 million people lived in food-insecure households. Food Recovery Network (FRN) is a non-profit organization that aims to reduce food waste on college campuses by donating excess, unserved food to local organizations that address food insecurity. This paper analyzes Lafayette College's FRN in Easton, Pennsylvania, as an eco-socio-technical system and specifically assesses its social costs and benefits to determine the value of FRN in reducing food waste and alleviating food insecurity. To estimate market and non-market costs and benefits, this study uses 2023 - 2025 data from the Lafayette FRN's food logs, community partner Safe Harbor, Lafayette's dining provider Parkhurst, and student survey responses. The data shows the number of people being fed, the type of food being donated, the amount of food being donated, the hours of labor designated to FRN, and students' willingness-to-pay, among other factors considered in this analysis. Findings will impact Lafayette FRN's decisions in its efforts to reduce food waste and food insecurity.

Abstract Name: Synthesis and Characterization of Rare Earth Layered Borates $\text{Ba}_3\text{Ln}(\text{BO}_3)_3$, $\text{Ln}=\text{Gd}, \text{Nd}, \text{Dy}$

Rare-earth layered borate with the general formula $\text{Ba}_3\text{RE}(\text{BO}_3)_3$ has attracted attention due to its magnetic-ion arrangement in a triangular lattice motif. These materials are known to crystallize in two distinct structural types. For $\text{Ln} = \text{La}-\text{Tb}$, the compounds adopt a trigonal structure (type I) with space $R\bar{3}$. In contrast, for $\text{Ln} = \text{Dy}-\text{Lu}, \text{Y}, \text{Sc}$, the compounds may crystallize either in the same trigonal structure (type I, space group $R\bar{3}$) or in a hexagonal structure (type II) with space group $P6_3\text{cm}$, depending on the synthesis temperature. Previous studies have revealed a range of exotic magnetic behaviors in this family with $\text{Ln}=\text{Yb}, \text{Er}, \text{Tb}$ etc. In this poster, we present the synthesis of $\text{Ba}_3\text{Ln}(\text{BO}_3)_3$, with $\text{Ln}=\text{Gd}, \text{Nd}, \text{Dy}$, and discuss the structural and magnetic properties.

Abstract Name: Where the City Breathes: Exploring Urban Climate Resilience and Public Health Through Green Spaces in Vienna, Austria

Climate change, one of the most pressing issues society faces today, has driven a sharp rise in global

temperatures over the past two centuries. While its effects are worldwide, urban populations face disproportionate mental and physical health impacts: an urgent concern as two-thirds of the world's population is projected to live in cities by 2050. As a result, this case study in Vienna, Austria investigates how urban green spaces (UGS) support citizens' mental and physical health, and how civic engagement can help shape community development under climate change pressures. The study used a mixed-method approach including semi-structured interviews with project organizers, surveys, and participant observation. Initial findings include that there are strong themes connecting public UGS accessibility with physical activity and stress reduction, as well as thoughtful UGS designs that help to support urban cooling. The research also found that when citizens participated in community-supported urban greening projects they felt more motivated about creating environmental improvements and gained great mental satisfaction from having a say in shaping their neighborhood and neighborhood projects. This research offers valuable insights into sustainable planning and policy that is aimed at promoting public health through the development of UGSs. It also showcases how community-driven engagement with these spaces can strengthen climate resilience in cities.

Abstract Name: HIV Integration Alters Host Gene Expression in CD4 T Cells: An RNA-Sequencing Study

Human Immunodeficiency Virus (HIV) establishes lifelong infection by integrating its viral DNA into the human host genome. According to the Centers for Disease Control and Prevention (CDC), approximately 1.2 million people in the United States are living with HIV, and nearly 13% are unaware of their diagnosis, underscoring the public health burden of viral infection. Chronic HIV infection is associated with cancer risk and genomic instability, driven in part by changes in host gene expression during viral replication. As HIV replicates in CD4 T cells, it integrates into transcriptionally active genomic regions that can further alter host gene expression. However, the extent to which integration orientation and genomic location influence host gene expression remains unclear. We aim to investigate how HIV integration impacts host gene expression by analyzing RNA-sequencing data from single-cell cloned CD4 T-cells. We use computational analyses to identify HIV integration sites, quantify chimeric splicing events, and examine changes in local gene expression. We hypothesize that sense-oriented integrations promote viral transcription and alter local host gene expression, whereas antisense integrations have less influence. Preliminary analyses show sense-oriented integrations within host genes such as RLF and ZNF292, accompanied by increased downstream exon expression relative to controls. By characterizing integration orientation and its impact on host RNA expression, this research advances understanding of how virus–host interactions drive transcription and may inform future therapeutic strategies targeting HIV persistence.

Abstract Name: Analyzing the Impact of Positive Youth Development Programming on Youth Critical Consciousness

Youth Participatory Action Research (YPAR) promotes valuable skills among youth such as critical thinking, civic engagement, and critical consciousness. Critical consciousness helps youth understand the world around them and believe that they can create positive social change. Egalitarianism and perceived inequality are two aspects of critical consciousness. Egalitarianism, or the belief that all people deserve equal rights, is a key component of critical motivation. Perceived inequality, or the ability to recognize social injustice, is the foundation for critical reflection. In the present study, we explored the impact of a YPAR intervention, Youth Voices (YV), on key aspects of youth critical consciousness. The YV program was designed to engage youth in educational activities that scaffold their thinking to address inequities in positive youth development opportunities. Participants were 155 predominantly African American/Black adolescents (ages 13–19 years; $M_{age} = 15.94$, $SD_{age} = 1.36$) with participants distributed approximately equally between the intervention ($n=77$) and control groups ($n=78$). Using one-way ANOVA regression analyses and controlling for baseline scores, gender, and age, results revealed that YV youth demonstrated significantly higher post-test egalitarianism scores ($F[1, 149] = 4.19$, $p = .042$, partial $\eta^2 = .027$) and perceived inequality ($F[1, 150] = 3.97$, $p = .048$, partial $\eta^2 = .026$) compared to control group youth. Results indicate that the YV intervention had meaningful positive effects on critical consciousness, highlighting the importance of YPAR in building aspects of critical consciousness in adolescents. Future research should explore which specific program aspects effectively promote critical consciousness and strategies to implement them into youth development initiatives to better support young people in being catalysts for change. Overall, the data suggest that youth programs can have a meaningful impact on aspects of critical consciousness, and we should continue to invest time and resources in these interventions to further positive youth development outcomes.

Abstract Name: How Iron Uptake Pathways Influence *Aspergillus fumigatus* Growth Across Different Iron Sources

Iron acquisition plays a critical role in the survival and virulence of *Aspergillus fumigatus*, an opportunistic fungal pathogen responsible for nearly 600,000 deaths each year. Invasive aspergillosis carries a mortality rate of 30–70%, especially among immunocompromised individuals such as organ transplant recipients, cancer patients, and those undergoing hematopoietic stem cell transplantation. In these patients, weakened immune defenses allow fungal spores to germinate and invade tissues, while excess iron can further enhance fungal growth and virulence. Understanding how *A. fumigatus* acquires and utilizes iron under such conditions is important for developing improved therapeutic strategies. This study examines how different iron uptake pathways affect *A. fumigatus* growth and metabolic activity. Wild-type (AfS77) and mutant strains lacking siderophore biosynthesis (Δ SidA), reductive iron assimilation (Δ ftrA), or both pathways (Δ SidA/ Δ ftrA) are being tested in media supplemented with Fe^{2+} , Fe^{3+} , heme, or hemoglobin. Fungal viability is being monitored using the Resazurin (RZ) assay in 96-well plates at 24, 48, and 72 hours. Data collection is ongoing, but early observations suggest that the disruption of iron uptake pathways leads to distinct growth patterns depending on the available iron source. These results aim to clarify the role of iron metabolism in fungal adaptation and may highlight new opportunities for antifungal therapy, particularly in iron-overloaded or immunocompromised patients.

Abstract Name: Development of a Printable Six-Axis Robot with Embedded Control for Cold-Plasma Wound Therapy

Cold Atmospheric Plasma (CAP) has shown to accelerate the wound healing process. The healing mostly occurs due to the reactive radicals entrained in the plasma. The wound surface is exposed to the plasma jet in a controlled manner. However, manual scanning lacks precision, risking uneven dosage and possible damage to surrounding tissues. To solve this we designed, built and tested a 6-axis arm which is fully Open Source clinically used for plasma therapy. Complete mechanical designing has been accomplished using Fusion360 and 3D printed with carbon reinforced PLA. Analysis predicts a 1.2 Kg payload mass while maintaining constant repeatability of 0.2 mm. High resolution, closed-loop NEMA-17 motors with backlash-free gearboxes provide 4.5 Nm peak torque at shoulder & elbow remove the need of external braking. Each joint features a redundant encoder which will trigger mechanical hard-stops and software emergency-off at a position error of greater than 0.5deg. The control hierarchy features a Teensy 4.1 microcontroller to handle 1 kHz motion loops (PID). Whereas Raspberry Pi 5 is responsible for high-level trajectory planning and human-machine interfaces. The system operates in a real-time Linux kernel. To keep the CAP nozzle 5 ± 0.5 mm above the surface with a velocity of less than or equal to 15 mm/s and acceleration of less than or equal to 50 mm/s^2 , blended Jacobian inverse kinematics was employed. These limits comply with ISO 13482 personal care robots. MATLAB model simulation achieved 98% path tracking accuracy when performed on a 3D printed anatomical phantom (R=40 mm cylinder). Fabricated system is under testing and results will be presented in the conference.

Abstract Name: Effect of Anode Size on the Properties of Constricted Hollow Anode Pulsed Plasma Source

With the advent of the ion thruster, burns requiring large velocity changes can be done with a fraction of the propellant compared to traditional chemical rocket engines. However, current ion thrusters produce thrust in the order of millinewtons and thus cannot be viable for launching vehicles or burns requiring velocity changes in a small amount of time. Furthermore, current ion thrusters experience grid and component erosion, where the two grids at the termination of the nozzle slowly erode due to particle impact and hot electrodes degrade due to high thermal load. This limits the life of ion engines, which require a long useful life to be practical. Additionally, current thrusters require lots of electrical power, often in the order of kilovolts, which requires large and heavy power supply components, detracting valuable payload mass. This research explores the use of a constricted hollow anode pulsed plasma source (CHAPPS) to generate high-density plasma in the constrained region to mimic the desired conditions in the ion thruster. Experiments are carried out in a vacuum chamber at operating pressure of 0.1-10 mTorr. Plasma is characterized by the Langmuir probe and emissive probe. Various electrode geometries are being tested to further optimize the density of the sinusoidal

plasma and thus achieve the best thrust density while avoiding the traditional pitfalls of electrode and grid erosion.

Abstract Name: "Alarming Antibiotic Resistance in Gram-Negative Bacteria from Canada Goose Droppings as a Public Health Concern"

Canada geese (*Branta canadensis*) are abundant in urban parks and outdoor spaces, where their droppings may serve as reservoirs of pathogenic and antibiotic-resistant bacteria. Understanding the microbial composition of goose droppings is essential to assessing potential zoonotic risks in shared environments. This study tested goose droppings collected from Secaucus, Wayne, and Jersey City, three locations situated near different bodies of water, including a lake, a river, and the Hudson waterfront. Gram-negative bacteria were isolated on MacConkey agar, with lactose-fermenting and non-lactose-fermenting colonies identified. Antibiotic susceptibility was evaluated using the disk diffusion assay with eight different antibiotics, including penicillin, ampicillin, ciprofloxacin, and tetracycline, which are commonly used in clinical settings. Hemolytic activity was assessed on blood agar to determine pathogenic potential. A substantial number of isolates displayed resistance to multiple antibiotics. The blood agar assay also identified colonies with beta-hemolysis, indicating the presence of potentially pathogenic bacteria. These findings suggest that urban goose droppings can harbor antibiotic-resistant and harmful bacteria, posing health risks for communities in shared environments. Future research will use molecular identification of isolates through 16S rRNA sequencing to characterize resistance genes and virulence factors, and will expand testing to include Gram-positive bacteria and additional clinically relevant antibiotics.

Abstract Name: Theory of Panspermia using mathematical concepts

This research is based on the application of the SEIR (Susceptible-Exposed-Infected-Recovered) epidemiological model to study the theory of Panspermia. The theory of Panspermia is the hypothesis that life can be transferred via interplanetary mechanisms such as meteoroids, comets, or interstellar dust. By adapting the SEIR model to represent the stages of microbial survival, shielding, transfer, and successful colonization in extraterrestrial environments, we investigate whether the spread of life across astronomical distances can exhibit dynamics analogous to contagion spread in biological populations. Our model simulates the survival probabilities, and under certain conditions, panspermia-like transfer processes can display threshold behaviors and propagation patterns similar to epidemic outbreaks, offering a quantitative framework to evaluate the possibility of life dissemination beyond Earth. Ultimately, this approach strengthens the scientific basis for evaluating whether life could realistically migrate and take hold beyond its planet of origin.]

Abstract Name: Extracellular Matrix Degradation by Severity of Pelvic Organ Prolapse

Introduction: Pelvic organ prolapse (POP), or descent of pelvic organs into the vaginal canal, affects up to 50% of women by age 50. POP is characterized by four stages of severity, with stage 1 representing mild prolapse and stage 4 representing complete prolapse. In POP, MMP2 and MMP9 degrade the vaginal extracellular matrix, while TIMP3 is an MMP inhibitor. This study aims to clarify the roles of MMP2, MMP9, and TIMP3 across POP stages. Methods: Full thickness vaginal biopsies were collected from patients with POP stage ≥ 2 and non-prolapse controls. Age within stage was matched by decade; closer matching was not possible within the study timeframe. We estimated 40 samples would provide 80% power with $\alpha=0.05$ to detect a moderate difference between groups. MMP9, MMP2, and TIMP3 were quantified by ELISA and compared between groups using Kruskal Wallis tests followed by Dunn post hoc comparisons. Results: Women with each stage of POP were older than controls (controls 48.8 ± 11.7 ; POP 62.5 ± 8.5 ; $p < 0.01$). MMP2 increased with increasing POP severity, with stage 4 patients demonstrating tenfold higher levels of MMP2 than controls ($p < 0.01$). MMP9 also increased across POP stages up to stage 3 (controls, 0.07 [IQR 0.17] ng/ug protein; stage 2, 0.25 [IQR 0.44] ng/ug protein; stage 3, 1.03 [IQR 1.36] ng/ug protein); then decreased in stage 4 (0.38 [IQR 0.81] ng/ug protein). Stage 3 and 4 patients exhibited more TIMP3 (0.63 [IQR 0.91] and 0.76 [IQR 0.91] ng/ug protein) than controls (0.09 [IQR 0.28] ng/ug protein) ($p < 0.01$). When controlling for age, TIMP3 remained elevated in later stages of POP ($p < 0.05$). Conclusions: ECM degradation increases with age and severity of POP through stage 3, while stage 4 may represent decreased remodeling.

Abstract Name: Differential White Matter Correlates of Screen Time and Dialogic Reading in Children Born Extremely Preterm

Children born extremely preterm (EPT) are at risk for altered white matter development, affecting language and cognitive outcomes. This study examined the differential effects of screen time and dialogic reading on white matter connectivity in 4–6-year-old EPT and term-born control (CTL) children ($n=15$ per group). Language and cognitive assessments included EVT-2, PPVT-4, CELF-P, and WNV. Demographics were reduced using Factorial Analysis of Mixed Data (FAMD) and clustered to control for group variability. Diffusion MRI data were acquired on a 3T scanner and analyzed using q-space diffeomorphic reconstruction and diffusion connectometry. Results revealed greater white matter connectivity in frontal tracts in EPT children, while CTL children showed greater connectivity in posterior, motor, and language tracts. These patterns may reflect delayed motor and language development in EPT children and distinct neural effects of environmental exposures. This study highlights the utility of connectometry in detecting white matter differences and supports the need for larger, longitudinal studies to explore the impact of screen time and early interventions like dialogic reading.

Abstract Name: Evaluating Salivary Protein Stability for At-Home Inflammatory Diagnostics

Human biofluids can be utilized for fast and easy disease detection and monitoring to improve patient treatment. Although underutilized, saliva has gained attention as a diagnostic fluid because it is accessible, non-invasive, and rich in proteins, cytokines, and inflammatory markers that reflect both systemic and oral health. However, variations in collection techniques and sample processing can influence protein concentration and biomarker stability, impacting reproducibility essential for clinical applications. This study tests whether saliva can generate reliable proteomic profiles using a low-input, high-throughput inflammatory assay when samples are processed immediately versus after 12–33 hours of delayed storage. Understanding salivary protein stability is essential for developing at-home diagnostic workflows for chronic inflammatory and immune-related diseases. The primary hypothesis is that inflammatory proteins measured in saliva using the NULISA 250-protein panel will remain stable and reliably detectable across immediate, overnight, and 33-hour post-collection processing. A secondary hypothesis is that, if stability is maintained, saliva could serve as a viable non-invasive alternative to blood and tissue for monitoring immune activity relevant to systemic inflammatory conditions, oral health, and other chronic diseases. Saliva will be collected from healthy adults using unstimulated passive drool, centrifuged to remove cells and debris, and analyzed on the ARGO HT platform using dual-antibody proximity ligation. Protein detection rates, biomarker expression, and profile stability will be statistically compared between immediate and delayed processing. We expect delayed processing will result in a slight decrease in protein quantity, resulting in some proteins not reaching detectable levels. Findings will provide insight into the feasibility of saliva-based diagnostics beyond clinical settings, enabling at-home collection and broadening opportunities for monitoring immune and inflammatory conditions across diverse populations. By addressing a critical gap in proteomic research, this study has the potential to advance scalable, non-invasive approaches for personalized healthcare and chronic disease management.

Abstract Name: Universal Robotic Controller: A Wearable Sensor Sleeve for Natural-Motion Teleoperation of Any Robotic System

The development of new robotic systems often requires creating a custom control interface for each platform, adding significant cost, time, and complexity to research and engineering workflows. This project addresses that challenge by investigating whether a single wearable device can serve as a universal, intuitive control system for any robot operating within the Robot Operating System (ROS) framework. Existing literature and

current industry practices indicate a growing interest in natural user interfaces for robotics, including gesture control, motion tracking, and wearable sensing. However, most systems remain robot-specific or limited in flexibility. Our Universal Robotic Controller (URC) seeks to make a unique contribution by offering a platform-agnostic controller that translates a user's arm, wrist, hand, and finger movements into standardized ROS commands. This approach aims to create a seamless control method for diverse robotic and mechatronic systems, including manipulators, mobile robots, quadrupeds, humanoids, and aerial vehicles, without requiring custom control interfaces for each device. Our methodology includes designing and fabricating a wearable sleeve equipped with sensors such as IMUs, UWBs, flex sensors, and pressure sensors to capture fine-grained motion. Sensor data is processed through onboard microcontrollers, filtered for noise reduction, and mapped to ROS topics representing position, velocity, or gesture-based commands. We will test the URC across numerous robot types to evaluate accuracy, latency, ease of use, and cross-platform compatibility. We expect the URC to provide a unified, simple, and adaptable control system capable of real-time teleoperation of any robotic project with high positional fidelity. With this project, we aim to reduce development overhead and complexity for robotic systems, improve human-robot interactions, and enable more natural motion-based teleoperation systems.

Abstract Name: IMPRIMIS: Self-Driving Ground Vehicle with Real-Time Obstacle & Lane Detection for Adaptive Path Planning

The mass adoption of autonomous robots in package delivery systems is limited by safety challenges, software complexity, and the high cost of sensing hardware. Our project addresses these barriers by developing an autonomous ground vehicle with a computationally efficient and safety-focused onboard computing system. The vehicle can navigate to specified coordinates while avoiding obstacles and maintaining lane position, using an array of sensors to build a real-time map of its environment. Our software architecture is built on the Robot Operating System (ROS), enabling modular data processing and flexible hardware integration. Key subsystems include localization, mapping, and navigation. Localization combines a tracking camera, IMU, GPS, and wheel odometry to estimate the robot's position, orientation, and speed. Mapping integrates LIDAR and camera data to generate a dynamic representation of the surroundings. The navigation stack uses this map to compute efficient, collision-free paths to the target destination in real time. All of these systems operate entirely onboard, removing the need for external base stations. The robot includes extensive safety features such as physical and wireless emergency stops, status-indicating lights and speakers, and resettable fuses. Its T-Slot frame supports modular expansion, and hot-swappable batteries with a backup electrical system protect critical components and ensure constant operation. We conduct rigorous testing to validate safety, improve accuracy, and advance autonomous performance. Through this work, we aim to demonstrate a practical, scalable approach to safe and reliable robotic delivery systems that can help lower the barriers to widespread adoption.

Abstract Name: Physical Activity and Anxiety in Hypertensive U.S. Adults: Findings from the National Institutes of Health All of Us Research Program

Hypertension is a highly prevalent condition characterized by a systolic blood pressure above 130 mmHg or a diastolic blood pressure above 80 mmHg. It presents a major cardiovascular risk, contributing to increased morbidity worldwide. Hypertension is commonly comorbid with mental health conditions such as anxiety, that can exacerbate cardiovascular outcomes and reduce hypertension treatment adherence. Engaging in regular physical activity can reduce symptoms of anxiety and improve cardiovascular outcomes, but studies using reliable wearable data in hypertensive populations remain limited. The purpose of this study was to examine the associations between physical activity data captured via Fitbit and clinically significant anxiety in hypertensive adults enrolled in the National Institutes of Health All of Us Program Dataset version 8 (2017-2023). Participants (n=1,972) were included for analyses if they had a diagnosis of both hypertension and anxiety reported in their electronic health record, were between the ages 18-91 years at the time of data collection, had at least seven valid days of Fitbit-measured physical activity data, and completed the Generalized Anxiety Disorder-7 (GAD-7) survey. GAD-7 survey data were dichotomized as either clinically significant (GAD-7 $\geq$ 10) or nonsignificant (GAD-7 $\leq$ 10). Logistic regression was performed to examine the odds of clinically significant anxiety for participants meeting or not meeting a clinically significant threshold of 7,500 steps per day. Models adjusted for age, sex, race/ethnicity, body mass index, and income. Participants meeting the 7,500 steps per day threshold were 39% less likely to have clinically significant anxiety (OR = 0.61, 95% CI: 0.43-0.84). These findings provide support for the role of regular physical activity as a strategy for improving both mental and physical health in hypertensive individuals.

Abstract Name: Dementia Prevention: Effects of cognitive screening and community education

Dementia is a growing health problem that affects not only individuals but also families and their surrounding communities. My research and community engagement aim to increase awareness of the early warning signs, modifiable risk factors, and strategies for living well after a diagnosis with dementia. As part of this project, I have been working on creating educational slide shows for the local community to help them recognize the potential early risk factors that could lead to dementia later in life and how to prevent those. These presentations are designed to be accessible and empathetic, combining every part of understanding with practical tools for prevention, early detection, and financial approach. I am certified to administer the Montreal Cognitive Assessment (MOCA), which is a widely used screening tool that helps identify early cognitive changes such as mild cognitive impairment. These sessions would help make a connection between clinical evaluation, and this will encourage individuals to seek further assessment and adopt healthy lifestyle habits that support their cognitive strength. As part of the project, I also started developing a Dementia Prevention Badge that community members can earn. Certification creates an easy and encouraging way for people to engage with dementia education and feel recognized for taking steps to care for their cognitive well-being. As part of the certification process, individuals can earn the badge through Credly. Through the work with the VCU College of Health Professions and the Richmond Brain Health Initiative, the main goal of this project is to offer an understanding of the feasibility of telephone screening to catch signs of dementia

early and provide access to dementia education through Badge certifications. In addition to describing the process and development, the frequency of utilization and feedback from the participants will be reported.

Abstract Name: In Vitro Models of Chondrocyte Inflammation to Evaluate for Therapeutic Testing

Introduction Osteoarthritis (OA) is a degenerative joint disease defined by chronic inflammation, chondrocyte dysfunction, and cartilage loss. Current OA therapies provide transient symptomatic relief but fail to alter the disease progression. Mesenchymal stem cells (MSCs) have shown promise in OA; however, work is needed to minimize clinical product variability. To study OA therapeutics, it is ideal to have an in vitro model that enables strategic monitoring of therapeutic functional capacity. In these studies, we developed a human chondrocyte model aimed at providing a tool to follow MSC function before in vivo testing. We hypothesize that knee chondrocytes can be utilized to develop an effective model for in vitro validation of MSC pre-clinical.

Methods To mimic the OA environment, human chondrocytes (AlloSource) were cultured in the presence and absence of human granulocyte-macrophage colony-stimulating factor (GM-CSF, 200ug/ml) under normoxic (21% O₂) and hypoxic (5%) conditions. Chondrocyte viability and metabolic activity were quantified using the WST-8 assays (Sigma Aldrich). Chondrocyte gene expression was quantified using qPCR for GAPDH (control), IL-6, COL2A1, and COL10A1 in duplicate, measuring cycle threshold differences from GAPDH (mean Ct $\pm$ SD, n=2).

Results GM-CSF stimulation induced metabolic stress in chondrocytes across both oxygen conditions, with WST-8 fluorescence increasing as the GM-CSF concentration was escalated. Real-time PCR (qPCR) analysis of chondrocytes treated with GM-CSF (200ug/ml) demonstrated a 2-fold increase in COL2A1, from 32.92 $\pm$ 0.04 mean Ct at baseline to 34.01 $\pm$ 0.05 with GM-CSF. COL10A1 collagen gene expression also increased 2-fold, from 32.78 $\pm$ 0.01 to 34.20 $\pm$ 0.02 with GM-CSF treatment. IL-6 exhibited no significant difference between treatment groups compared to GAPDH.

Conclusion These findings demonstrate the development of a promising in vitro model capable of evaluating anti-inflammatory therapeutics such as MSCs. This work has the potential to streamline therapeutic development for treating chondrocyte-based diseases such as OA.

Abstract Name: Identifying Target Pathways and Drug Repurposing Candidates for Syndromic Microphthalmia-12 (MCOPS12)

Microphthalmia Syndromic-12 (MCOPS12) is a rare genetic neurological disorder characterized by intellectual disability and motor dysfunction, including hypotonia, dystonia, and severe gross motor delay. It is caused by mutations in the Retinoic Acid Receptor Beta (RARβ) gene, which can result in either gain-of-function (GOF) or loss-of-function (LOF) variants. RARβ is highly expressed in the medium spiny neurons (MSNs) within the striatum and dopaminergic pathways, both of which play essential roles in motor control. A key variant of interest, p.Arg387Cys, causes a conformational change in the RARβ protein, increasing its affinity to retinoic acid (RA) and leading to excessive transcriptional activation. However, literature suggests that both GOF and LOF RARβ variants ultimately contribute to RA deficiency, resulting in consistent phenotypes across GOF and LOF animal models. As part of a collaboration with the Cure MCOPS12 foundation, the Hugh Kaul Precision Medicine Institute (PMI) is investigating therapeutic targets for MCOPS12. One pathway of interest involves mitochondrial dysfunction and MSN vulnerability caused by RARβ LOF, leading to the downregulation of the gene Pgc1α. A literature review and AI-assisted analysis using the NCATS Biomedical Translator AI tool identified several FDA-approved compounds with the potential to restore mitochondrial function through Pgc1α modulation. These findings will be compiled into a research report for the Cure MCOPS12 foundation to guide further preclinical testing.

Abstract Name: AI-Enhanced Creative Problem-Solving Tools for Higher Education and the Workforce

Artificial Intelligence (AI) is rapidly transforming how individuals learn, think, and solve problems, creating new opportunities for students to develop the creative and analytical skills needed in an evolving workforce. This project investigates how AI tools can support creative problem-solving by assisting users in clarifying challenges, generating original ideas, and developing practical solutions for academic and professional tasks. The central purpose of this project is to examine whether AI can function as an effective partner in creativity rather than a replacement for human thinking. The research focuses on widely accessible AI platforms, including ChatGPT, Copilot, and similar generative systems. A mixed-method approach is used: participants complete short problem-solving exercises, once without AI and once with AI support. Surveys and reflection prompts capture how AI influences idea generation, organization, and decision-making. Additional qualitative data are collected through open-ended responses that describe how users perceive AI's strengths, limitations, and impact on their confidence when approaching unfamiliar or complex problems. The study contributes to a growing conversation about responsible and meaningful integration of AI into higher education. While AI can accelerate brainstorming and offer diverse perspectives, it also requires careful use to ensure that students remain active thinkers and not passive recipients of automated suggestions. The project aims to identify best practices that encourage responsible use while enhancing creativity, originality, and problem-solving efficiency. Expected results include increased idea diversity, improved clarity when defining problems, and greater student confidence during early stages of creative work. These findings will be discussed in the context of preparing students for a technology-driven workforce where human creativity and AI-supported thinking must operate together. Ultimately, this project highlights how AI can expand access to innovative thinking and support students in developing the flexible, adaptive skills needed for future leadership and career success.

Abstract Name: Pathways to second chances: A multidisciplinary integrative review of 25 years of research on the employment of formerly incarcerated individuals

In this paper, we present an integrative review of the research literature on the challenges and opportunities surrounding the employment of formerly incarcerated individuals (FIIs). Our primary aim is to integrate 25 years of multidisciplinary evidence into vocational behavior scholarship, offering an employment life-cycle framework that identifies research gaps and practical implications for employers. Grounded in a multidisciplinary approach, we synthesize research across various domains, including criminal justice, psychology, sociology, law, economics, and management, to provide a holistic understanding of the systemic barriers that hinder FIIs' reintegration into the workforce. We introduce an integrative framework that examines the employment life cycle of FIIs, encompassing recruitment, selection, onboarding, development, and retention. We also highlight the critical role of social stigmatization, lack of access to vocational training, and the systemic disconnection between correctional institutions and labor market demands. Furthermore, our review emphasizes the importance of employer engagement and policy interventions in fostering inclusive hiring practices that support the successful reintegration of FIIs. We conclude with a call for future research and practical recommendations focusing on individual, organizational, and systemic factors that influence successful FII employment, highlighting the necessity of tailored vocational programs, social network support, and supportive workplace practices.

Abstract Name: Effects of Truncation on Vorticity of Delta Wings

Wing rock, an induced oscillation about the longitudinal/rolling axis, is one of the most serious issues that can be encountered in a delta wing aircraft. This oscillation, once it occurs, often exponentially grows in intensity, rapidly developing into an unrecoverable flight condition, which results in the catastrophic loss of the aircraft and endangers the pilot's life. The danger of this flight condition is compounded by the dramatic loss of lift that occurs when the oscillation is induced. The specific type of oscillation observed in this phenomenon is scientifically classified as a limit cycle oscillation. A vortex is a mass of fluid that spins around a central axis, forming a powerful, whirling current (just like tornadoes). While multiple factors contribute to this oscillation, the primary cause is rooted in the substantial asymmetry that develops in the opposing streamwise vortices. Within a range of speeds and Angle of Attack, one of the vortex breakdowns occurs earlier than the other, which results in asymmetry of vortices and leads to a self-sustaining loop of oscillating lift forces beneath the wing, resulting in wing rock. This vortex phenomenon has been well documented in earlier studies related to traditional pointed delta wing designs. The current study explored one of the possible solutions, to use a Truncated Tip Delta Wing, to prevent the induced oscillations resulting in wing rock. This design change was inspired by configurations emerging in hypersonic and high fuel efficiency aircraft. However, exceptionally little research has been carried out on them. Dye flow visualisation was utilised to understand the vortex dynamics on truncated delta wings. The additional leading-edge vortex stimulated the

merging of opposing streamwise vortices and aided in avoiding limit cycle oscillations. All in all, the current work bridged the gap by circumventing wing rock to create safer future aircraft.

Abstract Name: Mapping Pediatric Provider Deserts: Visualizing Rural Health Disparities Across Georgia

Behind every data point is a child waiting for care. In Georgia, the gap between where children live and where pediatricians practice reveals an invisible crisis one that geography alone can predict. This research maps pediatric care accessibility across all 159 Georgia counties to uncover how place shapes a child's chance at health. Using data from the Health Resources and Services Administration, the Georgia Department of Public Health, and the Georgia Board of Health Care Workforce (2023–2024), pediatric provider-to-child ratios were calculated, mapped by county, and classified as rural or urban using U.S. Census definitions. The results expose a startling truth: 63 counties in Georgia have no pediatricians at all, leaving thousands of children dependent on distant, delayed, or emergency care. Urban counties averaged nearly four times more providers per 10,000 children. By transforming these disparities into vivid, data driven maps, this project reframes access to care as not just a logistical issue but a moral one. It argues that visualization is advocacy: that policymakers can no longer ignore what they can now see. This research calls for targeted interventions telehealth expansion, rural provider incentives, and community-based health programs to bridge the divide between where Georgia's children are born and where they can finally be cared for.

Abstract Name: Exploring the Link Between Hot Flashes and Body Image in Breast Cancer Patients Undergoing Chemotherapy

Background: Cancer treatment for breast cancer (BC) can trigger vasomotor symptoms such as hot flashes. Biologically, hormonal changes and disruption in thermoregulation can reinforce a sense of illness, while psychologically, the hot flashes may induce feelings such as loss of control and dissatisfaction with one's body, contributing to negative body image. Both hot flashes and depression have been independently linked to poorer body image. Methods: 141 women diagnosed with BC (stage I-III), experiencing insomnia, and receiving chemotherapy were recruited for a clinical trial assessing a behavioral intervention for insomnia. Patients completed demographic and medical information, European Organisation for Research and Treatment for Cancer Quality of Life Survey (EORTC), and a daily sleep diary to report frequency of hot flashes and depression weekly average levels. Partial correlations were performed to determine the associations between hot flash frequency and EORTC body image questions, while controlling for depression. Results: 46.1% of BC reported presence of hot flashes, and 75.38% of BC reported feeling some level of depressive symptoms. Depression was significantly correlated with hot flashes ($r = 0.211$, $p = 0.013$). Hot flash frequency was significantly correlated with lower overall EORTC body image scores ($r = -0.202$, p

=0.018), as well as greater dissatisfaction with one's body ($r = 0.179$, $p = 0.037$), and difficulty looking at oneself naked ($r = 0.257$, $p = 0.003$). Patients with hot flashes were also significantly younger ($M = 47.23$ vs. 52.42 years, $p = 0.004$) compared to patients without hot flashes. Conclusion: Average hot flash frequency was significantly associated with more negative body image scores among breast cancer patients undergoing chemotherapy after controlling for depression. These findings display the association of vasomotor symptoms, particularly hot flashes, and body image perceptions during cancer treatment. Future research should explore the biopsychological mechanisms underlying this association and interventions to target symptom management.

Abstract Name: The Effect of Simulated Microgravity on Bacterial Resistance in Clinically Relevant Antibiotics such as Vancomycin and Ampicillin

As humans prepare for long-duration spaceflight, understanding how microgravity affects antibiotic resistance is essential for safeguarding astronaut health. Vancomycin, a first-line antibiotic used to treat *Enterococcus faecium* infections, plays a vital role in preventing disease. During spaceflight, astronauts' gastrointestinal microbiomes are exposed to a harsh environment of increased radiation and physiological stress from the microgravity, which can weaken the body's immune defenses. Having a dysregulated immune system in an isolated environment—such as the International Space Station, where medical resources are limited—poses a risk for infections and the growth of vancomycin-resistant *Enterococcus* (VRE). This research delves into how antibiotic resistance in relevant clinical medications, such as vancomycin and ampicillin, changes under simulated microgravity. Studies supported by NASA have shown that certain bacteria, including *Enterococcus faecium* and *Staphylococcus aureus*, reveal alterations in gene expression and increased antibiotic tolerance under microgravity conditions. These studies generally use rotational vessels or two-dimensional clinostats to mimic the microgravity conditions on Earth. Results from the Biodesign Institute at Arizona State University indicated that the minimal inhibitory concentration (MIC) increased by fourfold as it went from $8 \mu\text{g/mL}$ under normal gravity to $32 \mu\text{g/mL}$ under the simulated microgravity. This finding affirms that it took more vancomycin under the microgravity conditions to halt bacterial growth, suggesting that *E. faecium* develops a higher resistance to the antibiotic in microgravity. These findings highlight the importance of continued research on the antibiotic resistance of significant disease-preventing drugs under microgravity. Deepening insight into how space conditions influence bacterial behavior and the effectiveness of medications is crucial for improving medical protocols and astronaut health, in the support of humanity's expansion beyond planet Earth and the advancement of planetary sciences.

Abstract Name: Relations Between Emotional Attributions in Maternal Narratives and Infant Attachment

The transition to motherhood is marked by emotional complexity as mothers adapt to meet infant needs. Reflective functioning (i.e., ability to interpret children's behavior by considering their thoughts and feelings) has been linked to sensitive caregiving (Rutherford et al., 2023). Moreover, the outward expression of emotions influences the development of infant attachment patterns (Sroufe, 2005). This study explores mothers' expressions and attributions of emotions in reflections about motherhood and their association with their child's attachment. First-time mothers wrote ten narratives reflecting on perinatal experiences (positive, challenging, and milestone) during pregnancy and at 4, 8, and 12 months postnatal. At 12 months, infant attachment was observed using the Strange Situation Procedure. Conversations were coded for emotion language. To capture the frequency of mothers' references to emotional states or reactions, an instance-based coding system was employed (Syed & Nelson, 2015). Utilizing a consensus coding approach (Bohanek et al., 2025), a team of researchers coded each instance of emotion, indicating whether it was attributed to the self ("I was happy") or to another, thereby indicating reflective functioning ("She was happy"). The total number of self-attributed and other-attributed emotion words in each story will be used in analyses. We selected mothers of infants from different attachment categories—secure (N = 4), avoidant (N = 4), resistant (N = 4), and disorganized (N = 4)—to examine whether maternal emotion language differed across categories. We found that mothers of securely (v. insecurely) attached infants included less reflective functioning (indicated by a lower other-to-self emotion word ratio). Greater use of self-focused emotion words might reflect the mother's better understanding of her own emotional experience, which has been found to support secure attachment (Main et al., 1985). Identifying emotions linked to insecure forms of infant attachment may help inform early interventions designed to support mother-child bonds during critical developmental stages.

Abstract Name: Effect of Mineral Fillers on The Drying Time of Cellulose Fibers When Using a New Energy Efficient Drying Method

Paper manufacturing is one of the world's most energy-consuming industries. Lumber processing consumes approximately 7,200TWh of electricity annually, approximately 4% of world's usage. Drying processes account for 64% (4,698TWh) of this energy. Industrial processes involve grinding lumber into a water-saturated pulp. Typically, a dilute suspension of fibers is formed in water and then rolled into water-saturated sheets. After pressing, these sheets contain 60% water content. Reducing the water content further is an energy-intensive process because water molecules in cellulose fibers are retained by hydrogen bonding, Van-der-Waals forces, electrostatic interactions, and hydrophobic effects. This study investigated a novel dehydration process designed to accelerate the drying of cellulose-fibers while reducing energy consumption compared to heated roll-to-roll paper machines. The new drying process operates on the principle of di-electrophoretic, extracting excess water molecules within the fibers. Building on previous work from the author's laboratory, this presentation addresses the research question of quantifying the decrement in drying time when fillers (CaCO₃) are used in handsheets. The tests utilized TAPPI standardized hardwood-pulp handsheets. The air humidity varied from 50-95%, and the flow velocity was 2 m/s. Two high-voltage electrodes were designed, fabricated, and tested. Preliminary results showed that commercial printing paper containing fillers yielded a dehydration rate of over 30% whereas the dehydration rate of TAPPI handsheets ranged between 6-18%. The experimental results also indicated that, up to a certain level of sample moisture content, the newly developed drying method presented in this work required less energy to remove moisture from the sample compared to thermal heating. This was because it was efficient to selectively pick and move the water molecules away from the fibers than to heat up the entire system to overcome latent heat. The

experimental findings served as the basis for further experimentation and techno-economic analysis of the electrostatic-assisted paper drying technology.

Abstract Name: Understanding the Role of FOXA1 and FOXG1 in Regulating Chromatin Accessibility

Transcription factors (TFs) regulate gene expression through interactions with both DNA sequences and the surrounding chromatin environment. While many transcription factors rely primarily on intrinsic sequence preferences, pioneer factors have the ability to engage nucleosomal DNA and promote chromatin opening. These contrasting behaviors highlight the influence of chromatin context on transcription factor function, even among proteins with conserved DNA-binding domains. The Forkhead (FOX) family exemplifies this concept. Although FOX proteins share a highly conserved DNA-binding domain, only paralogs such as FOXA1 act as pioneer factors, whereas others like FOXG1 do not. This raises a key question about how paralogs can produce distinct regulatory outcomes in the same cellular environment. Understanding these differences in the FOX family is essential for explaining how developmental gene expression pathways are shaped and how specific TFs perform specialized regulatory functions. To investigate how these paralogs influence chromatin structure, we analyzed chromatin accessibility following the induction of FOXA1 and FOXG1 in mouse embryonic stem cells. An ATAC-seq workflow was used, including quality control, alignment to the mm10 reference genome, read filtering, peak calling with MACS2, and downstream visualization. We also performed motif discovery and comparison with TF binding data (ChIP-seq) to determine which newly accessible regions represent direct FOX factor targets. Results indicate that for both TFs previously accessible sites become more accessible, and also that the TFs open a varying amount of previously closed sites after induction. Overall, our findings demonstrate differential chromatin opening activities between FOXA1 and FOXG1 and indicate the role of chromatin context in shaping paralog-specific regulatory activity.

Abstract Name: Elucidating Chromatin Remodeling Mechanisms in Learning and Memory Across Development

Post-mitotic neural plasticity is the ability for mature, non-dividing neurons to functionally adapt and learn in response to environmental changes across the lifespan. Although fully differentiated, neuronal function can still be influenced by developmental stage-specific changes in gene regulation. Chromatin remodeling enables neural plasticity by altering gene accessibility through loosening or tightening of chromatin structure. Chromatin accessibility is thought to support experience-dependent transcription in mature neurons. However, across many organisms, the mechanisms by which specific chromatin remodelers influence learning and behavioral adaptation in fully differentiated neurons remain unclear. *Caenorhabditis elegans* (C.

elegans) is an ideal model because its neurons are post-mitotic after L1, chromatin remodeling genes are conserved, and mutants exhibit stage-specific learning deficits, suggesting developmental modulation of chromatin function. In this study, we examined eight chromatin regulator mutants representing diverse chromatin-modifying functions — including histone acetylation and methylation — with several expressed in neurons and implicated in transcriptional mechanisms relevant to learning, focusing on the L4-to-adult transition, a developmental window marked by dynamic changes in chromatin remodeler expression (Sun & Hobert, 2021). Learning was assessed using aversive olfactory conditioning, in which animals associate an attractive odorant with starvation. Wild-type worms formed a negative association, showing a significant decrease in chemotaxis. Interestingly, some chromatin remodeling mutants failed to form this association, showing no significant decrease in chemotaxis to the odorant after conditioning. These same mutants also exhibited blunted locomotor maturation: wild-type worms normally increased forward movement and decreased reversals to support the L4-to-adult transition, whereas this refinement was diminished in the mutants, suggesting a link between neuromaturation and learning capacity. To validate these findings, temporal control of chromatin regulator function between the L4 and adult stages will be performed using the auxin-inducible degron system. Overall, this work contributes to understanding how chromatin regulation shapes experience-dependent learning in post-mitotic neurons.

Abstract Name: Aging Bones Across Species: A Comparative Study of Skeletal Degeneration and Interventions in Humans and Non-Human Primates

Skeletal aging is a growing health concern as our populations live longer. It is characterized by decreased bone mineral density (BMD), changed bone structure, and an increased risk of osteoporosis. These changes contribute to frailty and a reduced quality of life in older populations. Rhesus macaques (*Macaca mulatta*) serve as a valuable comparative model for understanding human bone aging because they share similar physiology, lifespan patterns, and age-related degenerative processes. Here, we examine and connect insights from peer-reviewed literature to identify cross-species patterns of skeletal decline and to evaluate how sex, environmental factors, and intervention strategies influence bone loss. The analysis incorporates studies examining age-related shifts in BMD, cortical thickness, and overall skeletal structures in both humans and non-human primates. Across species, current research shows parallel declines in bone strength with age, with females exhibiting faster rates of loss linked to hormonal changes. Environmental factors, such as diet quality, level of physical activity, and living conditions, consistently shape the severity and trajectory of skeletal degeneration. Evidence from experimental studies on nutritional, hormonal, and lifestyle interventions, including vitamin D supplementation and structured exercise, demonstrates measurable improvements in bone health, although outcomes vary based on sex, age, and baseline health status. These findings suggest that skeletal aging results from the combined effects of biological and environmental influences that operate similarly across primate species. A clearer understanding of these shared patterns can improve how we predict bone-related conditions like osteoporosis throughout a person's life and support more targeted and preventative approaches to maintaining bone health across the lifespan.

Abstract Name: The Influence of Epigenetic Modifications in the Intergenerational Transmission of PTSD

Post-traumatic stress disorder (PTSD) is a trauma and stressor-related psychiatric condition whose effects can extend beyond individuals directly exposed to traumatic events. Growing evidence suggests that epigenetic mechanisms, heritable changes in gene expression that do not alter DNA sequence, play an important role in the intergenerational transmission of trauma-related vulnerability. This presentation examines three major epigenetic processes implicated in PTSD inheritance: DNA methylation, histone modifications, and RNA regulation. Research on populations exposed to extreme trauma, such as Holocaust and genocide survivors, shows that altered methylation patterns at stress-related genes can be transmitted to offspring, contributing to dysregulation of the hypothalamic pituitary adrenal (HPA) axis and increased sensitivity to stress. Animal studies further demonstrate that paternal stress can reprogram sperm through changes in DNA methylation, small noncoding RNAs, and retained histone marks, leading to measurable effects on offspring behavior and stress responsivity. Although each epigenetic mechanism has been studied independently, emerging research highlights extensive crosstalk among pathways, suggesting a complex and dynamic regulatory network underlying transgenerational trauma effects. Epigenetic insights hold promise for improving diagnostic markers and informing targeted biological interventions, however, such approaches raise concerns about off-target effects and the potential to disproportionately affect trauma-exposed or marginalized populations. Importantly, not all inherited epigenetic changes are maladaptive-- some may promote resilience and adaptive stress responses. Ultimately, effective PTSD treatment and prevention will require integrating biological, psychological, and social perspectives. As the field advances, epigenetic research offers a powerful framework for understanding how trauma and resilience can be transmitted across generations, shaping future strategies for personalized mental health care.

Abstract Name: Effect of Triple Therapy with Sildenafil, Rapamycin, and Doxorubicin in a Mouse Model of Breast Cancer

Breast cancer is one of the most frequently diagnosed cancers in women in the United States. Although the chemotherapy drug, Doxorubicin (DOX), is widely used for breast cancer, it leads to the development of drug resistance and multi-organ dysfunction, including severe cardiac complications. Our previous studies revealed that Sildenafil (Sild, Phosphodiesterase 5 inhibitor) potentiated the antitumor efficacy of DOX, while ameliorating DOX-induced cardiotoxicity. Additionally, rapamycin (Rapa, an inhibitor of the mammalian target of rapamycin, mTOR) protects the heart against myocardial injury. In this study, we examined whether a novel combination therapy with Sild and Rapa can mitigate DOX-induced cardiotoxicity, potentiating its chemotherapeutic efficacy. Female Balb/c mice were orthotopically implanted with 4T1-Luc murine breast

cancer cells. After 10 days, tumor-bearing mice were treated with Sild (1.4 mg/kg/daily, p.o.) and Rapa (0.25 mg/kg, twice weekly, i.p.). DOX was administered intraperitoneally 5 times (3 mg/kg, twice weekly, total 15 mg/kg). Tumor growth and body weight were monitored twice weekly for up to 42 days after implantation. 18 days after completing DOX treatment, cardiac function was assessed using echocardiography, then hearts and tumors were collected for further studies. Myocardial apoptosis was examined by TUNEL assay of the paraffin-embedded cardiac sections counterstained with Actinin (marker of cardiomyocytes). DOX treatment reduced tumor growth and weight, which were attenuated by Sild+Rapa cotreatment. DOX significantly reduced cardiac function in tumor-bearing mice compared to control groups. Notably, cotreatment of Sild+Rapa with DOX effectively restored the cardiac function in the tumor-bearing mice. TUNEL assay of cardiac sectioning displayed higher cardiomyocyte apoptosis in DOX-treated mice, which was suppressed with Sild+Rapa cotreatment. Cotreatment with Sild and Rapa may represent a novel strategy to reduce cardiotoxicity associated with DOX, simultaneously enhancing its chemosensitivity, with potential significance for breast cancer patients undergoing chemotherapy.

Abstract Name: Development of an Iterative Gait Cycle Detection Method Using Video Based Pose Data for Gait-based Early Autism Screening

Gait-based autism screening methods could be more accessible, scalable, objective, and easy to deploy. Reliable gait cycle identification is a critical step in a gait-based autism screening application being developed by the research team I belong to. My work is to create a gait cycle detection algorithm for extracting meaningful gait features from smartphone videos. We process pose estimation signals from running MediaPipe on real recordings of children walking in natural environments. Our approach combines signal analysis with an iterative strike-fitting scheme. First, we trim the beginning, end, and turning portions of each recording to isolate straight walking. Within each segment, we force the algorithm to place a specific number of right and left heel strikes. These strike positions must be roughly evenly spaced, must alternate between sides, and the counts must follow the condition that the difference between right and left is no more than one. For each possible configuration of strike positions, we compute a strike fitness score. This score measures how close the proposed strike positions are to the nearest peaks in the raw signal, such as peaks in a composite leg motion curve that indicate a true heel strike. The score is then normalized by the number of strikes. We repeat this process while varying the number of expected strikes and eventually keep the configuration with the lowest score. We propose a novel definition of the fitness score to reflect the true structure of the gait cycle, while remaining robust to noise in the pose data. Computational experiments have shown our method works well on various videos. Enhancement in process includes machine learning models to improve accuracy across different walking styles. By producing cleaner and more reliable gait cycles, this work supports downstream gait feature extraction and gait-based autism screening models.

Abstract Name: Effects of Musical Tempo on Cardiovascular and Neural Activity

Heart-rate variability (HRV) has been documented to correlate with several health measures, including autonomic nervous system longevity and athletic performance. Although increasing age has not been shown to affect resting heart rate, there is a steady decline in HRV over time, which serves as a biological marker of aging and autonomic nervous system function. Additionally, men who exercise regularly tend to have higher HRV, suggesting a mitigation of the typical age-dependent decline. Previous research has proposed that music may produce physiological effects, such as changes in cardiovascular parameters or emotional state, yet little is known about the quantitative influence of different musical tempos on these physiological measures. The present study aims to examine the effects of high-tempo and low-tempo music on blood pressure (BP), heart rate (HR), heart-rate variability (HRV), and electroencephalogram (EEG) readings. HR and BP are well-established indicators of physiological change, and the addition of HRV and EEG may offer further insight into autonomic and neural responses to music. Participants will complete an institutional review board (IRB)-approved protocol. All major musical variables are held constant to protect internal validity. Genre, instrumentation, and volume will be fixed for every participant, and all subjects will listen to one of two preselected classical piano pieces. The goal of this study is to better characterize how musical tempo influences physiological and neurological markers and to contribute to a deeper understanding of music's role in modulating autonomic nervous system activity.

Abstract Name: Characterization of Genetically Matched p53 Mouse Glioma Cells and the Impact of ATM Inhibitor Radiosensitization on the Tumor Immune Response

ATM (ataxia telangiectasia mutated) kinase plays a critical role in regulating the DNA damage response (DDR), including cell cycle checkpoints, DNA repair, apoptosis, and the response to certain growth factors and hormones. ATM kinase phosphorylates >700 proteins in response to ionizing radiation (IR) including the tumor suppressor p53. The Valerie lab has explored the use of ATM inhibitors to radiosensitize glioma in preclinical studies for more than a decade resulting in a clinical candidate ATMi (AZD1390) and a phase I trial at VCU-MCCC and other medical centers. Our earlier results showed that human mutant p53 glioma tumor models grown in immunodeficient mice were preferentially radiosensitized over p53 wild-type resulting in >50% survival of the former but short of a 100% cure. Whereas glioma is considered to be a 'cold' tumor, unresponsive to immune therapy, it is believed that wild-type p53 tumors have a more favorable tumor immune environment (TIME) than mut-p53 tumors. Therefore, how do we maintain effective ATMi radiosensitization and at the same time turn glioma into a 'hot' tumor? To determine the role of p53 in glioma

ATMi radiosensitization and the TIME requires an immune competent tumor model in order to apply immune checkpoint blockade (ICB). Therefore, we generated a genetically matched mouse glioma cell pair only differing in p53 status. We found that the expression of p53 gain-of-function (GOF) mutant R172H (R175H in human) in p53 wild-type mouse glioma cells inflicted a pronounced phenotypic change in line with a metabolic shift known as the “Warburg effect” associated with p53 mutant tumors, including elevated release of lactate and pH acidification, abrogation of the G1/S checkpoint, increased growth rate, mesenchymal cell appearance, and increased cell migration in vitro. We are currently determining the role of p53 in the glioma TIME and impact on ATMi radiosensitization and immune therapy.

Abstract Name: The Racism Hiding Under Society's Bed

This paper is searching for the hidden voices within horror and an ode to all minorities who have died first so that the white characters could survive. This paper looks into films that have aimed to rewrite the racial stereotypes commonly used in horror movies and how they did it. This paper is an evaluation of racial commentary within the American horror genre and what thematic elements have helped flourish this cinematic discussion between the films and their audiences. This evaluation looks at both the strengths and shortcomings of certain films that have been incorporated into racial discussions and their overall impact. To start the evaluation two subgenres will be under investigation on their potential cohesion with the horror genre and the ability to enhance the depth of the commentary presented in the films. Then Stephen King's power with horror adaptations will be questioned and the positives and negatives of his impacts will be reviewed. Rounding out the research component of this essay, the commonalities between scores and filming techniques will be dissected to better comprehend their roles within the commentary being made and how it can all be used to teach commentary. Finally, three horror films will be cross examined with the information that was researched and examined for the components that made their commentary strong. Scary Movie's mocking nature will be compared with Circle's bluntly liberal approach in attacking all -isms which will also be compared to Sinners's racial villain and cultural approach in order to predict which style resonates best with particular audiences based on their strategies.

Abstract Name: Nothing vs. Everything: Do We Give Less When We Have More? A Brief History Of Interpretation On The Rich Young Ruler

The story of the Rich Young Ruler (RYR), which is present in all three synoptic gospels, is one of Jesus' most well-known stories and receives extensive attention within the Church's history of interpretation. Upon examination, there is an interesting interpretative contrast regarding the Church's understanding of Jesus' command to the Rich Young Ruler (RYR) depending on the Church's historical and financial context. The pre-Constantine church (a persecuted religious sect) interpreted Jesus' command literally; however, the post-Constantine church (an eventual national religion with monetary influence) began to view this passage with an allegorical interpretation. This stark contrast reveals a possible link between the socio-economic context of

ancient Christian interpreters and their resulting interpretation of Jesus' command. In my paper, I am going to address a couple of questions: did the context of ancient interpreters affect their interpretation of "sell all your possessions"? If so, how? How does John Wesley's theology of wealth synthesize with ancient interpreters? Did the institutionalized status of the Church—and the financial power it brought—play a role in shifting the Church's understanding of generosity (particularly when considering the RYR)? To answer these questions, I am going to present a case study that analyzes one pre-Constantine and one post-Constantine interpreter's understanding of the RYR—both of whom will be synthesized with John Wesley—and consider the influence that financial power has on the interpretation of Jesus' command. The end goal of this case study is to better understand the potential influence of economic status within the historical understanding of wealth and generosity—which in turn presents a call for contemporary churches to analyze how their own socio-economic status may influence their theology of wealth.

Abstract Name: Understanding Relapse After Treatment: A Synthesis of Individual and Social Predictors

Background: Relapse after discharge from residential substance-use treatment is a major challenge to long-term recovery. Both individual (e.g., symptom severity, coping skills, motivation for change) and relational factors (e.g., family functioning, social support, recovery environment) influence post-treatment outcomes. While predictors have been identified, our understanding of their relation to long-term outcomes is limited, as prior studies typically track these predictors only short term (1-3 months). Effectively preventing relapse requires leveraging comprehensive datasets, like NTIES, that measure individual, social, and treatment-related predictors over a crucial 12-month follow-up period, filling this critical knowledge gap. Objective: This project will use NTIES data to identify key individual and relational predictors of relapse outcomes over 12 months following discharge from residential substance-use treatment. Methods: This study utilizes the NTIES dataset to examine long-term relapse predictors, analyzing outcomes for 4,411 participants with 12-month follow-up. We examine individual factors (e.g., symptom severity, self-esteem) and relational factors (e.g., social support, recovery environment) on relapse and, statistical analysis employs linear regression to assess predictors of relapse at the 12-month mark. Results: We anticipate that higher symptom severity, lower coping skills, and reduced motivation for change will be associated with increased relapse risk at 12 months post-discharge. Additionally, weaker social support, poorer family functioning, and less stable recovery environments are expected to predict higher relapse rates in the long term, strengthening the evidence base beyond typical short-term (1-3 month) follow-up periods. Discussion: This project will clarify the factors most strongly associated with long-term relapse (at 12 months) after treatment discharge. Understanding these persistent predictors is crucial for guiding effective discharge planning and developing long-term recovery support strategies. Identifying consistent patterns across the rigorous NTIES data allows us to fundamentally improve sustained recovery outcomes and influence clinical practices and policy decisions.

Abstract Name: Impact of Guardian Death During Childhood on Cluster B Personality Disorder Development

There are a number of factors that go into the development of personality disorders. Researchers have investigated what factors provide a risk for developing personality disorders. We are investigating guardian death, during childhood in particular, as being a risk factor for the development of cluster B personality disorder traits, which include: Borderline Personality Disorder, Histrionic Personality Disorder, Narcissistic Personality Disorder, and Antisocial Personality Disorder. Past research, such as Lahti (2012) and Brennan (2002), have explored the connection between separation of parental figures and the development of personality disorders. According to research, like Brennan (2002), Pert (2010), Wilcox (2010), involving parental death and the psychological repercussions have shown that it can lead to developmental traits such as those related to personality disorders. Drawing on this evidence, we are investigating the relationship between guardian death during childhood and developing cluster B personality disorders. We used the The Personality Inventory for DSM-5, otherwise known as the PID-5, the Short Dark Triad, and the Dirty Dozen Scale to assess dark triad traits such as narcissism, machiavellianism, and psychopathy. Central research questions are, “will participants who report death of a guardian during childhood score higher for Cluster B personality disorders, specifically dark triad traits, compared to participants who didn’t report guardian death?” With this question we can investigate if there’s a correlation between guardian death during childhood and the development of a cluster B personality disorder within the subject. Deliberation of the risk factors in developing personality disorders is essential to discussing preventive or predictive measures of developing a personality disorder. Considering the relationship between trauma and their contribution to developing personality disorder traits, we can further investigate how guardian death impacts specific aspects of personality disorder development such as Cluster B personality pathology.

Abstract Name: The Impact of Masking on Stress Reactivity in High-Functioning Autistic Adults

Autism spectrum disorder (ASD) is characterized by struggles with social communication, restricted interests, and repetitive behavior (American Psychiatric Association [APA], 2022); however, these struggles are not always noticeable. One might purposely hide these struggles in order to fit into a neurotypical society. Autistic individuals can achieve this through masking. Masking is the conscious or unconscious suppression of autistic traits to make oneself appear not autistic in social situations (Cremone et al., 2023). We are investigating the stress reactivity while masking in high functioning autistic adults. In order to assess the stress reactivity of masking with the galvanic skin response we used previous studies as a template. GSR also referred to as electrodermal activity (EDA), and skin conductance response (SCR) is the momentary change in skin conductivity in reaction to an emotionally arousing stimulus and is a widely used biometric indicator of stress (Jovanovic & Norrholm, 2016, pp. 292–316). Drawing on this evidence, we are investigating the stress reactivity of masking in high functioning autistic adults, specifically in the FGCU community. To assess the degree of Autistic traits within participants we used a survey consisting of the Autism Quotient, otherwise known as the AQ, Ritvo Autism Asperger Diagnosis Scale Revised, otherwise known as the RAADS-14, and Camouflaging Autistic Traits Questionnaire, otherwise known as CAT-Q. We predict that participants scoring higher for autistic traits, will show more stress reactivity during masking relative to participants scoring lower for autistic traits as measured by an eye tracking and galvanic skin response assessment. Research indicates that the use of masking behavior among ASD adults is used in protective ways to support their preventive or predictive mental health and physical outcomes. Considering the

relationship between masking and its contribution to a physiological stress response, we can further investigate how masking impacts high functioning autistic adults.

Abstract Name: Differences in the Epigenetic Landscape of Diffuse Large B-Cell Lymphoma (DLBCL) and Hodgkin Lymphoma (HL)

Cancer is an aggressive disease characterized by the uncontrolled growth of cells caused by improper gene expression. Lymphoma is a type of cancer involving the lymphatic and immune systems. This cancer affects young and old people alike, and subtypes like Diffuse Large B-Cell Lymphoma (DLBCL) and Hodgkin Lymphoma (HL) have high rates of remittance and resistance. Furthermore, recent advances in the field of genomics have changed the way we understand and study cancer. By looking at methods of regulating gene expression without altering the underlying DNA sequence, called epigenetics, researchers are beginning to piece together a more comprehensive understanding of the mechanisms by which cancer develops. This project aims to look at the differences in epigenetic mechanisms between healthy cells and those affected by DLBCL and HL using publicly available data in both cell lines and patient-derived samples for each disease state of interest. By integrating patient-derived data with cell line data, this project aims to create a perspective that is an accurate representation of the in vivo epigenome, while maintaining a standard of comparison throughout the variability of patient samples due to the stability and consistency of most cell line epigenomes. This data will allow us to compare which genes are being transcribed (RNA-seq), where chromatin is open vs. closed (ATAC-seq), and potential regulatory elements (ChIP-seq). Ultimately, looking at these three data types in an integrative format creates a more comprehensive view of the disease. This project expects to uncover underlying factors that may explain why DLBCL and CHL present so differently despite sharing the same cell of origin. These results could be used to help create precision treatments and discover biomarkers that can predict prognoses.

Abstract Name: Predictors of Retail Tobacco Compliance Violations in a High-Smoking Rural County

This study examines tobacco retailer compliance, with a focus on community factors that may influence violations. Somerset County, Maryland, is home to approximately 24,910 residents, 59.7% of whom reside in rural areas, and 17.5% of the population is under the age of 18. With adult smoking rates twice the state average, the county faces a substantial health concern (University of Wisconsin Population Health Institute, 2025). Tobacco usage is established at an early age, with 9 out of 10 current cigarette smokers starting before the age of 18 (Centers for Disease Control and Prevention, 2024). Understanding retailer compliance is

therefore critical for lowering community-level tobacco use and reducing youth access. Total violations in fiscal year 2024 showed a sharp 90% increase, while fiscal year 2025 reflected a more moderate 50% change after the second quarter. These fluctuations raise important questions regarding enforcement activity, the involvement of youth cadets in compliance checks, and broader trends in law-enforcement warnings. Notably, convenience-store chains accounted for a disproportionate share of the county's violations. This prompted questions about whether larger retailers feel less deterred by fines or can easily reopen under new storefronts. Variation between towns suggests that compliance may depend on geographic and structural factors. This can include the degree of rurality and the ability of enforcement teams to consistently and effectively reach the most remote areas. These findings underscore the need to consider tobacco compliance in rural regions, particularly those with vulnerable youth populations and high smoking burdens.

Abstract Name: Exploring the Effect of the Black Superwoman Scheme on the Criminalization of Black Women's Emotional Responses in the Justice System

Black women in the United States experience disproportionate criminalization compared to white women. Studies propose a cause for this disparity is systematic racism and the legacy of slavery. The longstanding oppression of black individuals in America has paved the way for an intersectional impact for black women. A cultural framework shaped by this history is the Black Superwoman Schema (BSS), promoting emotional suppression and self-reliance among black women. However, the BSS is a coping mechanism that can fail. So, because black women already face systemic bias and criminalization in the justice system, the combination of suppressed emotions and pervasive stereotypes can lead to misinterpretation. Therefore, leading to arrests and denial of victimization. This project aims to suggest that the BSS may function as an unseen mechanism that fuels criminalization. However, empirical research has not yet explored this link – which makes this project a call for future research. The research in this project will be conducted using an integrative literature review. The first component synthesizes existing literature on the BSS framework and its effects psychologically and socially. The second component examines the criminalization of black women in the justice system through existing literature and publicly available body camera footage (as it relates to aggression and resistance). The final part integrates both components to theorize how the BSS and criminalization relate. Overall, this project's goal is to serve as a intersectional argument for the need for future research on the relationship between the BSS and the criminalization of black women in the justice system. This is due to the high rates of criminalization of black women and the lack of a specific answer. This project calls for exploration and identification of stereotypes that lead to criminalization of black women.

Abstract Name: Do Environmental Pressures Induce Natural DNA Uptake in the Plant Pathogenic Bacteria Belonging to the Genus Xanthomonas?

Horizontal gene transfer (HGT) is a process by which bacteria exchange genetic material, and this is proposed to be the process that is the driving factor for evolution of the pathogen. HGT occurs three ways in bacteria- natural transformation, transduction, and conjugation. Genome comparisons of plant pathogenic bacteria show evidence of horizontal genome transfer and these HGT events can be traced back to the mode of transfer. While transduction and conjugation have been experimentally demonstrated in different bacterial genera, natural transformation has been found only in few bacterial genera, and only two so far in plant pathogenic bacteria, namely, *Ralstonia* and *Xylella*. However, the fact that large regions of the chromosomal genome appear to be under exchange among the genomes of closely related bacteria, it is possible that bacteria belonging to other genera also have ability to undergo natural transformation, yet we do not know exact conditions under which this transfer occurs. Here we are assessing the favorable conditions under which the DNA uptake occurs via natural transformation in the genus *Xanthomonas*. So far, we have not observed a detectable uptake under different salt concentrations or under the apoplast and epiphytic mimicry environments, but additional optimization of stressors is being done to see if this changes. The findings from this study are expected to enhance our knowledge of unexplored modes of genetic exchange in *Xanthomonas* and the conditions that favor this method.

Abstract Name: From Shared Gaze to Shared Ideas: The Development of Joint Engagement Over Video Chat in Early Childhood

Infants are born into an increasingly social world, and they begin to engage in it right away. Joint visual attention (JVA), two parties jointly focusing attention on a common, physically present object, is a milestone in development. Approaching toddlerhood, children develop the ability to think and communicate in the abstract (rather than about only tangible things, as in the case of JVA). This study focuses on the less studied concept of joint engagement, which occurs when dyads or triads engage in a topic, event, or idea that isn't physically present. This study will compare bids of joint engagement between children and grandparents over Zoom to bids of joint visual attention. I will evaluate which of the two categories children respond to and initiate more themselves with age. Video recordings will be coded to mark the number of bids occurring in the interaction. Joint engagement bids will be designated if the initiator (grandparent, child, parent) initiates a conversation relating to past events, future events, explanations of concepts, internal state, open-ended questions, connections between physical objects and absent objects, or culture. A bid is deemed successful if the recipient verbally responds within context, shares gaze with the initiator, or nods in response. Using ANOVA analysis, I expect to find that children in the older age group, 3.5-5 years, will initiate more joint engagement bids than the younger age group, 1.5-3.5 years; whereas younger children will initiate more joint visual attention bids than the older group (main effects of age). I also expect to see a difference in gender, with girls initiating joint engagement more than boys by the time they reach the older age bracket (interaction). Uncovering joint engagement from toddlerhood to childhood is crucial to understanding how children begin to immerse themselves in their social environments with increasing complexity.

Abstract Name: Sex Differences in the Association between Reflective and Anticipatory Coping

Race-related vigilance is a pattern of anticipatory coping in preparation for future experiences of racial discrimination. Rumination is the repetitive focusing on memories or events that cause negative emotions. Research has shown maladaptive coping methods like rumination are risk factors for depression and can increase stress responses both physiologically and psychologically. While black men may face more systemic and structural forms of discrimination, black women have been shown to face more variable and interpersonal forms of discrimination. There is a clear relationship established between racial discrimination and poorer mental health but more needs to be done to examine the interworkings of the factors that cause this. There is also evidence that women experience more depression than men. This difference may be due to coping style, and is the target of our investigation. In a sample of 52 black men and women we examined the sex differences in the associations between race related vigilance and rumination (and its subscales, brooding, depression, and reflection). We found a strong positive relationship between race-related vigilance and rumination and rumination's depression subscale present in women that was not present in men. We also found an association between race-related vigilance and trait anxiety that was present in women but wasn't present in men. This could mean that though men endorse more race-related vigilance, women through rumination, are more likely to have poorer mental health.

Abstract Name: Dissecting UBR5 Recognition of TDP43 Fragments

In many forms of neurodegeneration, the human Tar DNA-binding protein 43 (TDP43) undergoes proteolytic cleavage resulting in fragments that can form toxic oligomers and aggregates within cells. Our lab has discovered that cells utilize a multi-layered approach for recognizing and degrading these proteolytic fragments to prevent harmful aggregates. Here, we are investigating their clearance by the E3 ubiquitin ligase N-Recognin 5 (UBR5) pathway. While UBR5 is known to ubiquitylate proteolytic fragments bearing positively charged N-terminal amino acids such as arginine, we have found that UBR5 can recognize TDP43 fragments irrespective of the N-terminal residue. From this, we hypothesize that UBR5 recognizes TDP43 fragments through interactions with mono-ubiquitylated lysine residues. To investigate this, we carried out site-directed mutagenesis to both create a lysine-lacking (non-ubiquitable) mutant fragment by replacing all lysine residues with arginine as well as to determine lysine priority by making individual Lys to Arg mutations. These constructs will be used to dissect the mode of UBR5 binding.

Abstract Name: Joint Visual Attention between grandparents and grandchildren through video chat during structured activities

Joint visual attention (JVA) is a coordinated focus on the same object between individuals, with the intent to share an experience with the other person, which can be developmentally important for young children. The central question of this research is to study how children establish and follow JVA through a Zoom call and how different structured activities can facilitate JVA. Prior research (McClure et al, 2018) has shown that starting at around 9 months of age, infants can establish JVA and follow gaze through a video chat. This study included children ages 18 months through 5 years as a period when JVA is developing. Triads of a parent, child, and grandparent were randomly assigned one of three conditions (control, read, play). Triads were instructed to complete eleven Zoom sessions, with the first and last sessions being a baseline and final session with no instruction and the middle nine sessions being structured activities designed to facilitate JVA. Triads in the control condition were not given specific instructions and were asked to video chat as they usually would. Observational coding was done on the videos to categorize instances of bids for JVA along with the initiator and recipient, whether the bid was successful, reason for success, if the object was visible, and the type of JVA (whether the object of focus was on the initiator or recipient's side of the screen). It is expected that the structured activities will lead to more child-initiated bids for JVA than those in the control condition, and that play activities will be more successful for younger children whereas book reading will be more successful for older children. These results may be used to instruct caregivers on the most engaging developmental activities for young children and remote partners to use during video chat sessions with one another.

Abstract Name: Somatization, Anxiety Sensitivity, and Contamination Fears in Latino Young Adults: The Moderating Roles of Cultural Stress and Family Conflict

Contamination fears are a common feature of obsessive-compulsive symptoms which are generally considered to be influenced by individual psychological factors. However, young Latinos often report higher rates of somatic distress as well as persistent cultural and familial stressors, which may shape how bodily sensations related to illness or contamination are experienced and interpreted, further influencing the development and maintenance of contamination-related fears. The present study examines associations between somatization and anxiety sensitivity with contamination fears in young Latino adults, and whether they are shaped by cultural stress and family conflict respectively. Data were collected from 421 Mexican-heritage young adults via the UTRGV Department of Psychological Science's Research Participant Pool (August-December 2023). Participants completed measures of somatization, anxiety sensitivity, contamination fears, family conflict, and cultural stress. Moderation models were conducted to examine whether family conflict and cultural stress shaped the links between somatization or anxiety sensitivity and contamination fears. Descriptive statistics indicated mild somatization ($M = 10.24$, $SD = 6.23$), low anxiety sensitivity ($M = 6.15$, $SD = 5.17$), low contamination fears ($M = 2.5$, $SD = 2.38$), moderate family conflict ($M = 9.97$, $SD = 2.53$), and moderate cultural stress ($M = 50.40$, $SD = 19.99$). Family conflict significantly moderated both the somatization-contamination fears ($p = .004$) and anxiety sensitivity-contamination fears ($p = .002$) associations, whereas cultural stress only significantly moderated associations between somatization-contamination fears ($p = .035$) and not anxiety sensitivity-contamination fears ($p = .058$). These findings emphasize the importance of familial and cultural contexts when examining contamination fears among young Latinos. Individuals who report higher levels of somatization or anxiety sensitivity may be particularly vulnerable to contamination fears in contexts marked by family conflict or cultural stress. These

results highlight the need for culturally-responsive assessment and interventions that address somatic experiences and family dynamics.

Abstract Name: Investigating Glycosaminoglycans in Glioblastoma Tumor Cells

Glioblastoma multiforme (GBM) is one of the most common and aggressive forms of brain tumors, often resulting in a poor prognosis for patients. Due to the limited effective treatment options, there is an urgent need for a deeper understanding of the cellular signaling pathways of GBM cells to develop new therapeutic targets. Proteoglycans are proteins found on the cell surface and in the extracellular matrix of GBM cells. Glypicans 1 and 3 are a type of proteoglycan that are involved in cell growth and proliferation for GBM cells. Both glypicans have glycosaminoglycan (GAG) chains, which are sugars that contain repeating disaccharide units. These GAGs impact the function and structure of the glypicans, often assisting in the regulation of cell signaling, growth, and migration. For this study, we learned cell culture techniques and used a Blyscan assay to measure the concentration of GAGs on the cell surface for multiple GBM cell lines. We quantified and compared the total number of GAGs on the cell surface of GBM cells containing glypicans 1 and 3 to GBM cells that lack glypicans. A higher presence of GAGs on the surface of cells lacking the glypicans could indicate the importance of this class of proteoglycans for the GBM cellular processes.

Abstract Name: The Effect of America's Colonization on Hawaii's Epistemology and Metaphysics: A Contrast of Hawaii's Presence in the World Fairs in 1867 and 1965

By contrasting Hawaii's presence at the 1867 and 1965 World Fairs, it becomes evident that American colonization significantly altered Hawaii's epistemology and metaphysics. Shifting the nation's self-representation from an independent, sovereign nation to a commodified and domesticated territory that fit the American narrative. Within the assimilation of Hawaii, natives lost sight of the epistemology and metaphysics that shaped Hawaiians, and carried them into the impactful sovereign nation they once were. The Western perspective found that Hawaiians were not in alignment with the traditional perspectives that shaped Western culture. Americans deemed Hawaiian knowledge and understanding as inaccurate and invaluable to progression within American society. The majority of Hawaii's metaphysics is grounded in religion, while religion and metaphysics that did not fit into a Christian framework were disregarded during the colonization of Hawaii. Both Hawaiian epistemology and metaphysics were orally passed through generations, as the language went unwritten until Westerners had Hawaiians do so for biblical translations. Because of the oral traditions, many pieces of Hawaiian epistemology and metaphysics were lost during the annexation process. Prior to annexation, Hawaii is seen in the 1867 World Fair as a sovereign nation, grounded in its impactful

epistemology and metaphysics. As opposed to the presence of Hawaii as an American state in the World Fair in 1965, where it is apparent that their epistemology and metaphysics have assimilated into a Western perspective.

Abstract Name: Reaction-Time Variability in Duchenne Muscular Dystrophy: Cross-Sectional and Longitudinal Analyses Across Development

Background: Reaction-time variability (τ) reflects fluctuations in cognition and relates to executive-function disruption. Although cognitive differences are well documented in Duchenne muscular dystrophy (DMD), developmental patterns of τ and comparisons with normative samples and mutation subgroups remain limited. Objectives: This study aimed to: (1) compare τ between age-matched DMD and normative groups; (2) assess τ differences between proximal vs. distal mutations; (3) evaluate one-year longitudinal change; and (4) examine associations between τ and BRIEF executive-function T-scores. Methods: τ was estimated via bootstrap resampling for NIHTB-CB Flanker (congruent, incongruent) and Dimensional Change Card Sort (color, shape) tasks. Group differences were tested using Wilcoxon tests, one-year changes with paired Wilcoxon tests, and longitudinal subgroup comparisons with two-sample t-tests. Associations with BRIEF scores were quantified using Spearman correlations. Results: Seventy-two boys with DMD completed baseline testing, and 37 completed one-year follow-up; normative data included 1,441 participants. τ distributions were positively skewed in both groups. Compared with age-matched norms, τ was elevated in DMD during middle childhood for DCCS Color ($p = 0.006$) and during early adolescence for Flanker Congruent ($p < 0.001$), Flanker Incongruent ($p = 0.000$), and DCCS Color ($p = 0.033$). Mutation-site differences were modest, with significant effects only for DCCS Color in middle childhood ($p = 0.029$) and Flanker Congruent in adolescence ($p = 0.03$). Longitudinally, Flanker Incongruent τ decreased over one year in middle childhood ($p = 0.00078$). Higher τ correlated with higher BRIEF Global Executive Composite scores across tasks ($p < 0.05$). Conclusions: Boys with DMD show increased τ relative to peers, particularly in adolescence. Mutation-site effects are limited, and τ in inhibitory control improves over one year. Higher τ aligns with greater executive-function difficulties, supporting τ as a sensitive cognitive marker in DMD.

Abstract Name: Sex Differences in Estrogen Receptor Alpha Expression in Glucagon-like Peptide-1 (Glp-1) Releasing Neurons

Glucagon-like peptide-1 (Glp-1) is centrally produced by preproglucagon (Gcg) neurons in the nucleus of the solitary tract (NTS) and plays a key role in suppressing appetitive behaviors. Preclinical studies suggest estradiol, the primary ovarian estrogen, also suppresses feeding and enhances Glp-1's anorexigenic effects. Although previous studies have identified estrogen receptor alpha (ER α) within male NTS-Gcg neurons, the extent of this relationship in females has remained unclear. Using immunofluorescence staining in adult male and female Gcg reporter mice, we examined ER α and Gcg expression and colocalization in the NTS. While overall densities of Gcg neurons and ER α -expressing cells were similar between sexes, females showed a higher proportion of Gcg neurons expressing ER α , and vice versa, suggesting stronger estradiol influence in the regulation of Glp-1 neurons in females. Next, we assessed whether local estradiol synthesis via aromatase, the enzyme that converts testosterone to estradiol, contributes to this mechanism. Immunofluorescence staining revealed higher aromatase expression in the NTS of males compared to females, indicating greater use of local estradiol production in males. These results contribute to what is known of estradiol and Glp-1's synergistic relationship by revealing sex differences in ER α colocalization. The higher proportion of ER α within Gcg neurons in females suggests that estradiol's anorexigenic effects may be more directly mediated in females than previously recognized. Additionally, identifying greater aromatase expression in males adds a new understanding to this relationship, indicating that local estradiol synthesis could compensate for lower ER α expression. These findings refine current models of estradiol and Glp-1 interaction by highlighting sex-specific regulatory mechanisms. Future research includes exploring how these mechanisms change across aging, particularly during menopause when circulating estradiol declines. Understanding whether potentially reduced ER α signaling in Gcg neurons or compensatory aromatase activity contributes to postmenopausal weight gain and metabolic dysfunction could reveal novel targets for age-related obesity interventions.

Abstract Name: The Impact of Gas and Oil Drilling Activity on Natural Gas Prices and Productivity

This study examines how gas and oil drilling activity affects U.S. natural gas prices and evaluates whether rig counts help explain or predict short-run movements in Henry Hub prices. Natural gas markets have become sensitive to both commodity price fluctuations and shifts in drilling intensity, yet the short-run relationship between rig activity, prices, and productivity remains unclear. Motivated by earlier research documenting co-movement between drilling levels and energy prices, we investigate whether similar patterns arise in weekly data and whether rig counts contain predictive information for natural gas price changes. Our dataset merges weekly Baker Hughes rig reports, which include total, gas-directed, and oil-directed rigs, with Henry Hub natural gas prices and WTI crude oil prices from the U.S. Energy Information Administration. Using this combined dataset, we begin with descriptive statistics and time-series graphs to illustrate week-over-week percentage changes in drilling activity and natural gas prices. These exploratory tools allow us to visualize short-run movements and identify periods in which rig activity and prices appear to shift together. To analyze co-movement and directionality more formally, we use correlation analysis and Granger causality tests to determine whether past changes in rig counts help forecast natural gas prices and whether price movements precede later adjustments in drilling activity. Our preliminary findings reveal modest but noticeable correlations between drilling activity and Henry Hub prices. The Granger causality tests show limited short-run predictive power from rig counts to natural gas prices, while price changes show stronger effects on subsequent changes in drilling. Overall, this project contributes to ongoing discussions about the

responsiveness of U.S. natural gas markets by providing evidence on short-run interactions between drilling activity and prices. The work offers a clean dataset, a transparent empirical workflow, and results that support future research on market dynamics, rig productivity, and short-run supply responses in natural gas production.

Abstract Name: Kumaraswamy Exponentiated Odds Ratio Family of Distributions

Continuous statistical distributions are essential for analyzing a wide range of datasets. In this project, we introduce the Kumaraswamy Exponentiated Odds Ratio Family of distributions, a new approach for generating flexible continuous models. By incorporating the exponentiated odds ratio, the proposed family gains greater flexibility and adaptability, which are important features when fitting modern datasets. We present the mathematical properties of the new family and provide simulation studies for its submodels. To assess how well the model fits these types of data, we apply several advanced estimation techniques. Simulation studies using Maximum Likelihood, Least Squares, Weighted Least Squares, Maximum Product Spacing, Cramér–von Mises, and Anderson–Darling methods confirm the robustness and efficiency of the proposed model. Real datasets further confirm that the Kumaraswamy Exponentiated Odds Ratio Family outperforms several existing distributions, demonstrating its relevance in both theoretical and applied statistical work.

Abstract Name: Anita Berber: Nackttanze and Liberation in the Weimar Republic

Nackttanze, or nude dancing, stands at the pinnacle of bodily liberation. This form of expression, which involves the eurythmic practice of translating sound into movement without the constraints of clothing, explores themes of gender and corporeality through performance. However, this paper examines how the oppressive environment created by a rising fascist regime limited the bold defiance of the movement, focusing on the notorious Weimar-era dancer, Anita Berber. The underground atmosphere of the Nackttanze style of performances challenged dominant concepts of eroticism and theatre. Understanding these themes is crucial for grasping the context of the German interwar period, a time marked by instability and a dangerous sociopolitical landscape. By closely analysing Berber's illustrious performances, the paper offers a reframed lens on her artistry. Additions of queer and feminist theory are used to contextualise the temporal and haunting constraints Berber and her contemporaries faced as acts of both literal and metaphorical spiritual transgression from a 21st-century perspective. Berber's delicate balancing act between ecstasy and vice, the

radicalism of dance as an art form, and its imprints on cultural memory are approached through the lens of a critic's relationship with space and language. This paper will explore the lyrical qualities of theatrical documentation as a means of capturing sensory ephemerality by delving into the nuances within Berber's performance. Various theatrical reviews, primary works by Anita Berber and a few of her contemporaries, and literature on nude dance reveal how resistance and vulnerability intertwine within the intimate and foreign realms of gender expression and cabaret theatre during interwar Germany.

Abstract Name: Research Barriers and Mentorship Quality

Undergraduate research is widely acknowledged as a high-impact educational practice, contributing to students' academic success, professional readiness, and retention (Bhattacharyya et al., 2018). However, disparities persist in access, mentorship quality, and institutional support, with many students reporting uncertainty about how to access opportunities (White et al., 2023). Prior research has found that stipends significantly influence participation, especially among underrepresented students (Edwards et al., 2024; Messier et al., 2013). Other studies underscore the critical role of mentor accessibility and supportive research environments (Behar-Horenstein et al., 2010; Byars-Winston et al., 2023). Little research has examined the impact of these identified barriers on undergraduate students who have and have not engaged in research. This project aims to assess barriers, perceptions, and opportunities surrounding undergraduate research participation across Kennesaw State University. A mixed-methods survey was distributed university-wide to investigate students' experiences with mentorship, awareness of research opportunities, and structural challenges. This project focuses particularly on the equity of access, the effectiveness of mentor relationships, and institutional visibility and communication for students engaged in research and those who are not. While data collection is ongoing, preliminary results indicate that student researchers rated their research mentors highly, particularly in serving as positive role models ($M = 4.53/5$) and fostering a welcoming research environment ($M = 4.53/5$). The most reported obstacles to research participation were external commitments ($M = 3.66/5$), lack of time ($M = 3.61/5$), and lack of awareness of opportunities ($M = 3.48/5$), suggesting that competing priorities and limited knowledge of options may hinder student engagement. These findings identify that actionable recommendations to university leadership, such as mentorship training, stipend programs, and centralized research resource directories, can further improve undergraduate research participation. The ultimate goal is to broaden participation, improve student outcomes, and strengthen the culture of undergraduate research at Kennesaw State University.

Abstract Name: Investigating the Effects of FTY720 in an In Vitro Model of Post-Traumatic Fibrosis

Post-traumatic fibrosis is an abnormal response to tissue repair that results in the excessive formation and deposition of extracellular matrix, leading to the formation of fibrotic tissue. The Sphingosine 1-Phosphate (S1P) pathway is activated during tissue regeneration, but its role in the formation of post-traumatic fibrosis is still largely unknown. FTY720 is an agonist for the S1P receptors and blocks S1P signaling. Here, our goal was to investigate the effects of FTY720 in an in vitro model of human post-traumatic fibrosis. Human bone-marrow mesenchymal stem cells (BM-MSCs) were treated with transforming growth factor beta 1 (TGFβ; 10 ng/mL) for 24 hours and FTY720 [1 nM to 100 nM]. Cell viability was assessed by the MTT assay. Expression analysis for the fibrotic genes COL1A1 and COL3A1 was performed by q-RT-PCR. Statistical analysis was performed using a two-tailed Student's t-test. Cell viability was significantly reduced $\geq 25\%$ following [30 nM] or higher concentrations of FTY720 compared to the control (Control: $100\% \pm 0.0\%$; TGFβ: $91.9\% \pm 4.9\%$, $p=0.10$; TGFβ+FTY720 1 nM: $98.0\% \pm 9.0\%$, $p=0.74$; TGFβ+FTY720 5 nM: $90.7\% \pm 3.3\%$, $p=0.04$; TGFβ+FTY720 10 nM: $95.5\% \pm 15.1\%$, $p=0.66$; TGFβ+FTY720 20 nM: $90.6\% \pm 8.9\%$, $p=0.21$; TGFβ+FTY720 30 nM: $75.1\% \pm 5.6\%$, $p=0.02$; TGFβ+FTY720 50 nM: $70.2\% \pm 8.3\%$, $p=0.03$; TGFβ+FTY720 100 nM: $69.0\% \pm 12.6\%$, $p=0.05$). COL1A1 and COL3A1 were slightly modulated following FTY720 treatment compared to the control (COL1A1: Control: 1.0 ± 0.0 ; TGFβ: 1.7 ± 1.5 ; TGFβ+FTY720 5 nM: 1.3 ± 0.7 , $p=0.56$; TGFβ+FTY720 10 nM: 1.2 ± 0.7 , $p=0.75$ and COL3A1: Control: 1.0 ± 0.0 ; TGFβ: 1.5 ± 0.6 , $p=0.34$; TGFβ+FTY720 5 nM: 1.3 ± 0.8 , $p=0.68$; TGFβ+FTY720 10 nM: 1.1 ± 0.6 , $p=0.87$). Altogether, our results support the notion that lower concentrations of FTY720 did not demonstrate significant cytotoxicity in BM-MSCs, and that the S1P pathway may play a role in the process of human post-traumatic fibrosis. Abstract Name: Chemical Analysis of RAD-140 from U.S. Retailers Reveals Chemical Impurities and Safety Concerns

This research examined the purity of RAD-140, a selective androgen receptor modulator (SARM) sourced from online retailers, to elucidate the dangers of purchasing these compounds from non-federally regulated sources. In a recent systematic review, Vignali et al. documented more than 30 reports of SARM-related adverse events, with the majority involving drug-induced liver injury. In response to similar events, several years ago Van Wagoner et al. examined the chemical composition of commercial SARMS, finding that 25% included undisclosed substances. Building on these findings, this study hypothesized that RAD-140 from a supplier reputed for high purity would align closely with published chemical characteristics, while other samples would differ significantly in melting points and ultraviolet (UV) absorbance. Samples from three prominent U.S. suppliers, selected based on search visibility and user discussions, were analyzed using melting point determination, UV-visible spectroscopy, and color assessment for comparison with literature values of pure RAD-140. Results revealed statistically significant melting point differences ($p < 0.05$; power 0.73–0.77) between two suppliers' samples, with one also showing divergent UV absorbance spectra. All samples displayed variable colors in raw and melted forms. These findings show inconsistent RAD-140 purity across suppliers, with one sample aligning with expected characteristics, another meeting standards unexpectedly, and the third suggesting impurities. Furthermore, this study generated secondary findings of accurate and reproducible melting point and UV absorbance values for RAD-140 that are not adequately

substantiated in the existing literature. These results highlight the inconsistent quality of commercial SARMS and the risks of purchasing from unregulated sources.

Abstract Name: In-Silico Analysis of Tensile and Compressive Stress-Strain in Idealized Arteries

Cardiovascular disease (CVD) is the leading cause of death worldwide, with atherosclerotic plaque rupture serving as the primary trigger for heart attacks and strokes. Because rupture occurs in regions of elevated mechanical stress, characterizing the arterial stress-strain environment is essential for predicting rupture-prone sites. Our laboratory has previously investigated plaque stability and arterial curvature using intravascular ultrasound imaging, evaluating effective von Mises stress and Lagrange strain. However, these analyses did not account for circumferential plaque location within curved arteries, a factor that may influence rupture risk. This study aims to compute and compare effective, tensile, and compressive stress-strain distributions in curved, idealized arteries by simulating combinations of curvature parameters. The artery model included three layers--the adventitia, media, and the plaque--each assigned physiologically accurate material properties. A pressure of 120 mmHg was applied to simulate systolic blood pressure in a cardiac cycle. A total of 185 simulations were performed, representing combinations of six percent-stenosis values, four curvature magnitudes, and nine curvature directions. For each case, median von Mises stress and Lagrange strain were computed using the tensor outputs from FEBio and separated by arterial layer. Median axial and radial tensile and compressive components were also calculated. Preliminary findings suggest that increasing percent stenosis generally decreases effective stress and strain within the arterial wall. Additionally, plaques located along the outer curvature exhibited reduced stress-strain magnitudes, indicating that circumferential positioning influences local mechanics. As expected, radial stresses and strains were predominantly compressive, while axial components were predominantly tensile. Plaques on the inner curvature experienced greater compressive loading, potentially elevating rupture risk. Current limitations include mesh resolution and plaque-generation variability. Future directions will be improving mesh density and plaque modeling in order to validate these trends.

Abstract Name: Roman Infrastructure and the Christian Narrative

Scholars have studied the spread of Christianity throughout the Roman Empire since the events themselves, focusing mainly on the extensive missionary force that operated during that time. While this focus is widely accepted, it raises questions about the methods employed by the missionaries and why they were so successful. Roman infrastructure significantly shaped early Christian missionary efforts by providing access

across the vast expanse of the Empire. This expansion led to a notable shift in Christian narratives, transitioning from apostolic persuasion to an institutional voice, which played a crucial role in Christianity's success and eventual dominance within the Empire. This concept was examined through the lens of the Roman city of Corinth, mentioned in multiple accounts in the New Testament and significantly impacting the functioning of the Pauline Church. Research was conducted using the limited physical and technological resources available within a remote setting, utilizing the databases of the University of Kentucky and Wheaton College. The conclusions reached differ from those found in previous research, leading to a unique perspective and contribution to the field. Ties were identified between the infrastructural advancements of the Roman Empire and the changes in Christian narratives. The missionaries' ability to travel long distances facilitated a shift from emotional, persuasive narratives to more institutionalized ones. This change is evident in various early Christian texts addressing Corinth, particularly in Paul's Letters to the Corinthians and 1 Clement, where the transformation occurs largely as a result of actions within the Corinthian Church.

Abstract Name: Exploring Ethanol's Impact on Zebrafish Embryonic Development as a Model for Fetal Alcohol Syndrome

Fetal Alcohol Syndrome (FAS) is the leading preventable cause of birth defects, with approximately 10% of pregnant women globally consuming alcohol. This results in an estimated 120,000 children born with FAS each year. To better understand the consequences of prenatal ethanol exposure, we turned to model organisms, specifically zebrafish, which have previously proven to be valuable in explaining the developmental impacts of ethanol. By conducting controlled studies, we were able to identify critical windows of vulnerability and explore the dose-dependent effects of ethanol exposure, which are difficult insights to capture in human clinical studies. We examined a range of ethanol concentrations (0%, 0.5%, 1%, 1.5%, and 2%) and exposure durations (4.5-10, 10-24, 24-48, 48-72-, and 4.5-72-hours post-fertilization), and various anatomical measurements were taken to assess the impact of ethanol on development. Our findings indicate clear dose- and time-dependent severity of abnormalities. Through this analysis, we have demonstrated the utility of zebrafish as a model for studying FAS and have enhanced our understanding of how embryonic exposure to ethanol disrupts development. These findings highlight the critical importance of avoiding prenatal ethanol exposure to help eliminate an entirely preventable condition.

Abstract Name: Oxygen, Sleep, and the 24-Hour Clock: Understanding an Overlooked Biological Link

Sleep and circadian rhythms are essential for human health, yet most research has focused on light as the primary cue that synchronizes the body's internal clock. Oxygen, despite being a fundamental component of cellular metabolism, may also play a significant but understudied role in regulating sleep and daily biological timing. This project reviews current findings on how changes in oxygen availability, both low oxygen (hypoxia) and elevated oxygen (hyperoxia), affect sleep quality, hormone rhythms, and the molecular

pathways that help maintain the 24-hour cycle. Studies from high-altitude environments and obstructive sleep apnea consistently show that hypoxia leads to fragmented sleep, reduced slow-wave and REM sleep, and altered nighttime melatonin levels, reflecting the brain's sensitivity to oxygen and the activation of hypoxia-inducible factor 1-alpha (HIF-1 α). This pathway interacts with core circadian clock genes, including BMAL1, CLOCK, PER, and CRY, linking oxygen levels to daily physiological rhythms. In contrast, emerging animal studies suggest that mild hyperoxia may deepen restorative sleep and improve recovery from physiological stress, though long-term human research is still limited. Together, these findings indicate that oxygen may act as a subtle environmental signal capable of influencing sleep architecture and circadian timing. Understanding this relationship may have implications for sleep medicine, high-altitude physiology, and potential therapeutic strategies aimed at improving sleep and aligning the internal clock.

Abstract Name: Exploring How a Conversational Agent Responds to Different Mental Health Symptoms: An Iterative Approach to Codebook Creation for Assessing ChatGPT's Mental Health Safety Guardrails

Introduction Healthcare is becoming increasingly advanced, with new technologies such as Artificial Intelligence (AI) offering innovative ways to address health concerns. However, there has been little research exploring the possible pitfalls of AI for vulnerable patient populations, specifically those with mental health concerns. Past research has demonstrated that the safety guardrails of conversational agents like ChatGPT, which are the monitoring systems that try to keep AI responses within safe and ethical boundaries, are not well-suited to detect psychological distress. The current project aims to expand upon these gaps by exploring ChatGPT's safety guardrails when presented with experimentally manipulated types of mental health concerns (i.e., depression, anxiety, and stress). **Methods** Four research assistants role-played help-seeking users to create transcripts (N = 420) reflecting a specific symptom type and severity. Each profile was created based on specific items and item-level Likert scores from the 21-item Depression, Anxiety, Stress Scale. These determined both the symptoms displayed (e.g., depression) and the intensity of the language (e.g., if severity = 3, they reported symptoms occurring daily), ensuring consistency in symptom presentations. As data collection is completed, we are piloting the codebook, which assesses response types (e.g., walks you through a coping skill) and the presence of guardrails (refers you to professional help). We will code the statements following the codebook and report our preliminary findings on the frequencies of presence of guardrails. **Expected Results** The results to be presented include the frequency distribution of how often ChatGPT 1) suggested seeking professional help and 2) expresses having human-like characteristics (i.e., ChatGPT referring to itself as a real person, such as stating "I'm right here next to you") Additionally, we will examine if distributions differ by symptom type. Findings will improve our understanding of ChatGPT's behavior in sensitive contexts and how guardrails can be improved.

Abstract Name: Factors Predicting Knowledge of Pre-Exposure Prophylaxis (PrEP) in College Students: Understanding the Role of PrEP-Related Stigma

Introduction Pre-exposure prophylaxis (PrEP) can reduce the risk of contracting HIV by ~99% if used as prescribed, making its uptake vital to ending the HIV epidemic. However, the scaling of PrEP has been slow in many target populations, including sexual minority men, transgender and gender expansive individuals, young women, and ethnic/racial minorities. These populations may be slower to adopt PrEP due to limited access to and awareness of resources. Multiple health behavior theories, such as the Health Belief Model and the Knowledge to Action Framework, posit that knowledge is the first necessary step for health-related behaviors to ensue. There is a lack of research aimed at exploring PrEP knowledge among college-age populations, despite the availability of accessible campus healthcare resources. The aim of this project is to address these gaps by examining the factors predicting knowledge about PrEP among college students.

Methods Sample size is projected to be ~350. Undergraduate students will complete a web-based survey assessing PrEP knowledge, PrEP-related stigma, provider trust, mistrust of healthcare systems, PrEP attitudes, and community support around PrEP. We will employ multiple linear regression to examine how multiple factors influence PrEP knowledge. Subsequently, we will run a moderated multiple regression to examine the role of stigma on these relationships.

Expected Results We hypothesize that positive attitudes towards PrEP, higher trust, lower mistrust, and higher community support will predict PrEP knowledge. However, we also theorize that there will be noticeable differences in the strength of different predictors. Lastly, we hypothesize that these relationships will be buffered by PrEP stigma.

Conclusion Results from this study will improve our overall understanding of factors influencing students' acquisition of PrEP knowledge. Understanding acquisition will help guide future research to improve campus sexual health interventions and identify distinct points of outreach during college to promote PrEP uptake.

Abstract Name: Race & Bias in the Courtroom

The lack of representation in the courtroom for Black Americans is a prevalent issue that contributes to race-based sentencing disparities. There are many assumed reasons why sentencing or determination of guilt may be harsher for Black Americans compared to White Americans. Systemic racism and potential bias among judges and jurors may heavily impact the outcome of a case for a minority defendant. By compiling my findings of perceptions and realities of racial disparities by role in the courtroom — judge and jury — we can develop a clearer understanding of the moving parts in the courtroom and the contribution they have in producing racial inequities in the justice system. Using a mock trial survey that I created myself, this project will test whether respondents perceive less racial bias in the judicial system when there is greater racial diversity among judges and jurors. Additionally, this project will examine respondents' judgment of the guilt or innocence of Black defendants in the context of varying racial compositions of judges and jurors.

Abstract Name: Beyond Monoracial Frameworks: Understanding Predictors of Suicide Ideation and Behaviors in Multiracial Youth

The Multiracial population in the U.S. is the youngest of any racial group, and experience a heightened risk for suicide (Garcia et al., 2019). However, a recent review indicated that only 11 articles to date have focused on suicide among Multiracial adolescents, and the majority tested ethnic-racial differences, rather than mechanisms underlying suicide (Williams et al., in press). This is a critical area that warrants investigation. In order to prevent suicide among this population, it is imperative to understand Multiracial youths' challenges and resilience; however, these topics are often neglected in research that is framed from a monoracial lens (Harris, 2016). For example, in the 11 aforementioned studies, Multiracial youth were only a part of a larger sample, and not one study focused on the impact of specific Multiracial challenges on suicide (Williams et al., in press). To address these gaps, the current study tested whether Multiracial challenges (Multiracial youths' experiences of others' surprise and disbelief regarding racial heritage, lack of family acceptance, and identity-based challenges) and skin tone satisfaction predicted suicide ideation and behaviors (i.e., suicide ideation, suicide plan, and suicide attempt). Participants in the current study were 644 Multiracial adolescents 13 to 17 years of age. We tested hypotheses using Mplus. Results indicated that skin tone satisfaction predicted less suicide ideation and suicide plans. Others' surprise and disbelief regarding racial heritage did not predict any suicide outcome. Lack of family acceptance and Multiracial identity challenges predicted greater suicide ideation, plan, and attempts. The pattern of findings suggests that suicide ideation and behaviors among Multiracial individuals may be more strongly influenced by stressors that undermine identity coherence or belonging.

Abstract Name: Improving Embedded Calibrations in Low Cost Sensing for Air Quality

The need for calibration of sensors in the low-cost sensing (LCS) research space is recognized. Outside research however, there is a common incorrect assumption that sensors from manufacturers produce accurate temporal trends and consistent behavior across units. This work will aim clarify why that assumption fails, highlight the need for greater communication and propose a stronger framework for embedded calibrations. Calibration is typically executed in two ways: embedded data analysis (EDA) or retrospective data analysis (RDA). EDA is typically performed by the manufacturer pre-market and is proprietary while RDA is performed post-market on collected datasets. These approaches are fundamentally different and non-equatable. EDA applies an instantaneous, one-dimensional linear operator fitting an input to an output; RDA

is performed with respect to an entire dataset, adding time as a dimension of information. Since low-cost sensors have limited onboard memory and computational power, EDA is typically performed using multivariate linear regression. However these calibrations can only predict behavior included in the training set, limiting the model's ability to extrapolate. Additionally, unstable coefficients in the model can introduce calibration artifacts into data such as elevated baselines or diverging sensor trends between units. These artifacts are often overlooked or poorly communicated and can be misleading in data analysis. My proposed framework to improve EDA utilizes a ridge multivariate linear regression variant that holds predictor coefficients to a specified sign and considers nonlinear predictors. The model is investigated with respect to CO and CO₂ sensors and compared to similar models: evaluating performance metrics such as MBE, r-squared, root mean squared error (RMSE) and numerical conditioning. My findings suggest this method is effective at reducing calibration artifacts. Utilizing this framework in conjunction with proper communication on EDA methods would reduce the impact of misleading sensor data and allows for more clarity in the usage of LCS.

Abstract Name: Sleep Issue Indications in Commercial Driver Medical Examination Reports

Commercial vehicle operators must be certified medically fit to drive on public highways at least every 2 years. The Commercial Driver Medical Examination (CDME) is used to evaluate commercial drivers' health and ability to safely perform their jobs. Obstructive sleep apnea (OSA) has been identified as a risk factor for drivers' safety on public roads, as OSA is linked to cognitive impairment, daytime sleepiness, and other health issues. However, there are no formal criteria for a medical examiner to decide when a driver with a sleep issue should receive an overnight sleep study used to diagnose OSA. In a study using data from 2005-2010, the CDME identified a sleep issue in only 20.7% of drivers who later had a positive diagnosis of moderate or worse OSA. These data were collected prior to a 2005 congressional mandate implemented in 2014 by the Federal Motor Carrier Safety Administration (FMCSA), which required specialized training and registration for medical examiners. We analyze data from 2018-2020 to assess the change in screening effectiveness of the CDME since the implementation of this mandate. We can accomplish this by examining changes in prediction performance measures such as sensitivity. Our dataset was created by combining written comments from CDME reports with OSA diagnostic test results. A key feature of our analysis was using regular expressions to identify sleep-related issues in examiner and driver notes. We then added this information to the existing dataset. The preliminary results of our work show minimal improvement in CDME screening effectiveness, despite the congressional mandate. The CDME continues to be ineffective at identifying sleep issues in drivers. A secondary analysis goal is to examine differences in CDME screening effectiveness across healthcare provider types (MD, DO, PA, APN, etc.).

Abstract Name: Project G.L.E.N.

Project G.L.E.N., formally known as “Enhancing Tornado Research: A Case for Transitioning the Enhanced Fujita Scale,” is an ongoing initiative aimed at advancing tornado research through the development and deployment of an unmanned tornado probe. Through the Gale Level Environmental Navigator (G.L.E.N.) probe, a remote-controlled unit equipped with specialized meteorological sensors and innovative design features, we aim to collect real-time, onsite data from within tornadoes. This approach allows for direct measurement of internal atmospheric conditions such as wind speeds, pressure fluctuations, temperature, humidity, and other storm dynamics while removing human risk from tornado interception, significantly enhancing the safety of storm research. Additionally, while current tornado ratings rely heavily on post-storm damage surveys, which may not accurately reflect the full strength or behavior of a tornado, Project G.L.E.N. seeks to provide a more objective basis for tornado classification, bridging the gap between damage-based assessments and recorded metrics. The project’s initial phase focuses on localized data collection to validate sensor performance, refine instrumentation methods, and optimize probe design. Collected data from our final, revised design will be analyzed for statistically significant trends, providing the empirical foundation for potential enhancements or revisions to the Enhanced Fujita (EF) Scale.

Abstract Name: Neurobehavioral outcomes following a forced abstinence from smartphone use

Smartphone users frequently report anxiety when separated from their phones (Panova T and Carbonell X 2018), often experience compulsive behaviors related to device use and engagement with social media (Sarman A and Çiftci N 2024), and may describe their experience as a “cell phone addiction” (Merlo LJ et al. 2013). Concern is increasing regarding the compulsive components of cell phone use, as well as potential negative effects such use may have on the brain (Lin H-M et al. 2022). Individuals reporting compulsive cell phone use can experience harmful effects to their relationships, finances, and safety (Merlo LJ et al. 2013). An important related phenomenon that is pervasive within social media culture is the unfavorable experience of the Fear of Missing Out (FoMO) on potential experiences, resources, and connections (Alutaybi A et al. 2020, Zhang Y et al. 2023). As cell phones are easily accessible, turning to devices and engaging with social media is a frequent reaction when experiencing FoMO (Zhang Y et al. 2023). Uncertainty remains around if smartphone use promotes states of addiction similar to substances such as alcohol and cocaine, and additional research is needed. In an investigation of a targeted population of adults who experienced forced abstinence from cell phone use resulting from voluntarily engaging in extended travel experiences in remote locations, this study utilized multiple standardized self-report survey instruments (Addiction Potential Scale, CORE Short Form, Mobile Phone Problem Use Scale, Problematic Use of Mobile Phones Scale, Bergen Social Media Addiction Scale, Fear of Missing Out Scale, and Problematic Internet Use Questionnaire) to investigate behavioral outcomes associated with a period of being separated from their phones. These findings will contribute to the understanding of maladaptive cell phone use and provide additional information regarding the similarities and differences between these behaviors and substance dependency.

Abstract Name: The Frequency of Microplastics in the Bats of Oklahoma

Our research sought to measure the prevalence of microplastics within the bat populations of Oklahoma and see if there was a significant difference in plastic accumulation between bat species. The bats used were acquired from different parts of Oklahoma from 2023-2024. These bats were submitted to the Oklahoma State Department of Health for rabies testing and then deposited in the University of Central Oklahoma Natural History Museum, where we were able to dissect them and collect their feces. The feces of 40 bats were examined under a microscope in search of any form of microplastics. Reference images of microplastics were used to identify possible plastics. Our results showed that 25 (62%) of the samples examined had some form of particulate plastic and when the samples were categorized by species, we found that there was a significantly higher percentage of evening bats (*Nycticeius humeralis*) contaminated with microplastics than other species of bats examined (eastern red bats, *Lasiurus borealis*, and big brown bats, *Eptesicus fuscus*). We are currently revamping our procedures and broadening our sample size. Firstly, we will be collecting the bat's feces, intestine, and lungs. This will allow us to see if there is evidence of microplastics not only in the bat's diet, but within the bat's tissue. While collecting our samples, we will also ensure that our samples are in glass vials, and all plastic surfaces are covered with aluminum. We will start using potassium hydroxide (KOH) to ensure all organic matter is dissolved. With what is left over, we will run it through an infrared (IR) spectrometer, so that we will be able to identify the exact type of plastics found. With these improved procedures, we will be able to discern how many and of what kind of microplastics are affecting our local bat populations.

Abstract Name: CAHOOTS Program Effect on Disorderly Conduct and Drug Arrest Rates in Eugene, Oregon

I study the impact of the CAHOOTS program - a response program led by health workers to police calls regarding mental health and drug related crises - on arrest rates in Eugene, Oregon, using difference-in-differences and synthetic difference-in-differences regression methods. This is where the difference in pre-treatment means between treatment and control groups are subtracted from post-treatment means of both groups to infer the effect of the CAHOOTS program on my dependent variables. I analyze agency-year data for Oregon police departments, examine disorderly conduct and drug arrests (overall and by race), and assess identification via graphical parallel trends. The results show an insignificant increase in arrests for disorderly conduct and a significant increase in drug arrests after the implementation of CAHOOTS. These findings imply that health-based police programs, such as CAHOOTS, may lead to an increase in drug arrests, improving the detection of those crimes and individuals not receiving the help needed.

Abstract Name: Supporting Student Use and Evaluation of AI Image Generation

This study explores the accuracy and benefits of the use of artificial intelligence (AI) generated images in educational assignments. Prior research highlights the need for structured frameworks and training that empower the critical evaluation of AI outputs to ensure reliability and promote ethical use. In this study, an assignment from an undergraduate course required students to generate images for a Picture Identification Test for Hearing-Impaired Children and evaluate their experience using image-generating AI. Students recorded their prompts, output, and modifications needed to retrieve their desired images, determining the accuracy of the AI-generated images. A series of Likert scale questions were used to report the correctness, composition, and contextual relevance of the images produced. Students then reflected on the image-generating process, considering how the integration of AI in the assignment prepared them for future clinical practice. It is expected that the AI evaluative and reflective elements of the assignment will support students' technology fluency with image-generating AI and support relevant application and critical thinking for career readiness.

Abstract Name: On Brain-To-Text Translation: The Ability to Predict Text from EEG Data

Brain-to-text translation is a relatively new concept within the fields of machine learning and neuroscience. It employs machine learning models to capture complex patterns in brain signals and translate brain activity into text. Most earlier studies used electroencephalography (EEG) data for this purpose, while others relied on functional magnetic resonance imaging (fMRI) or magnetoencephalography (MEG). In this work, we aim to determine whether brain-to-text translation can be achieved using end-to-end convolutional neural network (CNN) and attention models trained entirely from scratch. Our motivation stems from the fact that earlier work in this field often relies on pretrained models, and some employed teacher forcing during training. We used the ZuCo 2.0 dataset, specifically the natural reading portion, to train our models. Due to computational and time limitations, we used only 5 samples per subject (90 total) to train two models with identical architectures. One model used an unbalanced split of the dataset and achieved a word error rate (WER) of 71.88%, while the other used a balanced split and achieved a WER of 79.37%. The techniques employed show that it is possible to translate EEG data into words using basic CNN-Attention architecture with connectionist temporal classification (CTC) loss. For tokenization, we used byte-pair encoding (BPE) and did not apply beam-search decoding to improve output correctness. These results provide evidence that meaningful patterns are captured by the model within EEG data and that the model is not merely guessing or hallucinating its predictions.

Abstract Name: Inhibitory Effects of Garlic Scape Extract on Intestinal Carbohydrate Digestion and Absorption In Vitro

Hyperglycemia increases the risk of developing type 2 diabetes and other metabolic complications. Regulation of carbohydrate digestion and glucose transporters in the intestine is critical for controlling postprandial blood glucose. Garlic scapes (*Allium sativum* L.), the flower stalks of garlic plants, are commonly discarded as agricultural byproducts. However, it contains valuable nutrients and bioactive compounds with potential health-promoting effects. This study identified the best garlic scape cultivar for North Carolina and examined its extract on intestinal carbohydrate digestion and glucose uptake. Twenty-four hard-neck garlic cultivars were evaluated for scape yield traits and total phenolic content (TPC). Scapes were digested in vitro and extracted with 70% ethanol to obtain digested garlic scape extract (dGSE). Bioactive compounds of the dGSE were analyzed by LC-MS/MS and SPME-GC-MS. The dGSE's effects on in vitro intestinal carbohydrate-hydrolyzing enzyme activity, glucose uptake, and the expression of sodium-glucose cotransporter 1 (SGLT1) and glucose transporter 2 (GLUT2) in Caco-2 cells were examined using enzymatic, fluorescence, quantitative PCR, and western blot analysis, respectively. Music was selected as the best cultivar, with allicin and deoxyalliin as major bioactive compounds. dGSE inhibited the carbohydrate-hydrolyzing enzymes α -glucosidase, sucrase, maltase, glucoamylase, and α -amylase in a dose-dependent manner, with inhibition comparable to or greater than that of 1 mg/mL acarbose at low concentrations. dGSE at 40 μ g/mL decreased SGLT1 and GLUT2 by 32% and 30%, respectively. Consistent with this, glucose uptake was inhibited by dGSE, regardless of the presence of sodium. Taken together, garlic scapes may be a potential food for alleviating postprandial hyperglycemia.

Abstract Name: Modeling Seasonal Dynamics of Influenza in Wisconsin

Seasonality is a defining characteristic of many epidemiological time series, reflecting recurring patterns that repeat at regular intervals. Accurate characterization of these patterns is essential for influenza surveillance, forecasting, and public health planning. This study examines the seasonal dynamics of influenza incidence in Wisconsin using laboratory-confirmed case data from 2021–2025 provided by the U.S. Centers for Disease Control and Prevention (CDC). We systematically compare four approaches for modeling weekly time-series data: seasonal dummy variables, Fourier-based harmonic regression, Seasonal ARIMA models, and generalized additive models (GAMs) with spline-based smoothers. While a few recent studies (Yang et al., 2020; Zhu et al., 2022) have applied GAMs with splines to explore meteorological effects, our study is among the first to use this flexible modeling approach to capture the underlying seasonal structure of respiratory infection data. Results indicate that the spline-based GAM consistently outperforms the alternative

methods. It captures shifting peak timings, asymmetric seasonal curves, and multiple inflection points, the features that more rigid approaches, such as seasonal dummies and Seasonal ARIMA, cannot fully represent. Importantly, no evidence of overfitting was observed. The findings also suggest that influenza seasonality in Wisconsin has become more variable in the post-COVID era, emphasizing the need for adaptive, data-driven modeling strategies. By identifying the most effective method for near-term influenza modelling and forecasting, this study provides practical guidance for epidemiologists and public health practitioners in temperate regions. Overall, our research demonstrates that spline-based GAMs enhance influenza surveillance, improve operational forecasting, and advance understanding of evolving regional epidemiological patterns, offering a robust alternative to traditional time-series methods for contemporary influenza dynamics.

Abstract Name: Peripheral Cytokine Levels Predict Adverse Birth Outcomes in Pregnant Women

A healthy pregnancy must immunologically balance pathogen response and maternal-fetal tolerance. Adverse birth outcomes have various established distal risk factors, but proximate biological mechanisms are mostly unknown. Our goal is to analyze whether antenatal inflammation, measured by peripheral cytokines, can predict (1) gestational age at birth and birth weight percentiles and (2) preterm and low birth weight incidence. Peripheral blood samples were obtained from 98 pregnant Latina women living in Southern California through the Mothers' Cultural Experiences longitudinal study and analyzed using multiplex assays to determine the levels of cytokines at two timepoints (timepoint 1, <18 weeks gestation; timepoint 2, 20-33 weeks gestation). Questionnaires were administered to assess mothers' experiences during pregnancy at timepoint 3, 0-7 months postpartum. The relationship between cytokines and outcomes was analyzed using linear and logistic regression, with nonparametric covariate balance propensity scoring. At timepoint 2, higher levels of Th2- and Th17-derived cytokines, as well as individual cytokines IL-8 and IL-10, were associated with shorter gestation. Th2- and Th17-derived cytokines at timepoint 2 were also positively correlated with the incidence of preterm birth (<37 weeks) and low birth weight (<2500g). We found no effects for Th1-derived cytokines. Because Th2 cytokines are often interpreted as anti-inflammatory during pregnancy, and Th17 as extracellular pathogenic inflammation, our results reflect simultaneous upregulation of both anti- and pro-inflammatory responses associated with adverse birth outcomes. A possible interpretation is that as pro-inflammatory responses increase in response to extracellular infection, anti-inflammatory responses may also increase to protect the fetus. The upregulation of these opposing immune forces may ultimately contribute to or signal earlier parturition. More research is required to better understand whether the interplay between these opposing immune responses contributes to adverse birth outcomes.

Abstract Name: Early environmental enrichment improves Autism Spectrum Disorder (ASD) symptoms in a mouse model of ASD

Approximately, 1 in 31 children in the United States is diagnosed with Autism Spectrum Disorder (ASD), a neurodevelopmental disorder marked by social communication deficits, social interaction impairments, and repetitive behaviors and/or interests. Delayed cognitive and motor skills as well as increased anxiety and stress are also apparent. To date, off-label use of pharmacotherapies do not directly address underlying ASD pathology. The current study uses a mouse model of ASD to determine mechanistically how early exposure to environmental enrichment can ameliorate ASD symptoms. Methyl-CpG Binding Protein 2 (MeCP2) is an epigenetic mechanism that, when mutated, underlies some forms of ASD (Gogate, et al., 2024). Mutations of the gene encoding for *Mecp2* in mice lead to cognitive and social interaction impairments, anxiety, and motor coordination abnormalities (Gemelli, et al., 2006). Early environmental enrichment (EE), in which mice are exposed to running wheels, tactile stimuli, and social interaction during preadolescent stages, provides sensory and cognitive stimulation that enhances neural plasticity (Fang et al., 2025). Wildtype (WT) and mice in which *Mecp2* is knocked out (KO) in the brain were randomly assigned to EE or social isolation conditions. Mice were then exposed to various behavioral tests to assess learning and memory, cognitive function, social interaction, as well as depression and anxiety. Using EE in our mouse model of ASD, we demonstrate improvements in social interaction as well increased levels of Brain Derived Neurotrophic Factor (BDNF) in the hippocampus, a protein implicated in synaptic plasticity and neurogenesis (Barco, et al., 2005). We also show changes in dendritic morphology as a function of exposure to EE. Taken together, these data show that early exposure to EE can improve symptoms associated with ASD, presumably through its effects on hippocampal synaptic plasticity.

Abstract Name: Nosocomial *Candida auris* Infections Compared to *Candida* spp.: Drug Resistance, Pathogenicity, & Environmental Survival

This review explores cellular mechanisms conferring antifungal resistance, environmental survival, and increased pathogenicity in *Candidozyma auris* (formerly *Candida auris*) compared to other *Candida* spp. in the context of nosocomial candidiasis, specifically candidemia. *C. auris* is a novel *Candida* yeast most commonly causing candidemia, which carries high mortality rates. High environmental survival and persistent skin colonization by *C. auris* presents a significant challenge for prevention of outbreaks, resulting in recurrent candidemia outbreaks. Furthermore, the limited availability of antifungals and *C. auris*'s frequent multi-drug or pan-drug resistance limits therapeutic options for the treatment of candidemia by *C. auris*. *C. auris* is also frequently misidentified by traditional methods. Comparison of *C. auris* and other clinically relevant *Candida* spp., such as *C. albicans*, *C. glabrata*, *C. haemulonii*, and *C. parapsilosis* was conducted by research on population-based surveillance and case studies. Epidemiological trends indicate a shift away from *C. albicans* towards *C. glabrata* and other *Candida* spp., due to prophylactic fluconazole use selecting for azole-resistant species. Comparison between the haploid structure of *C. auris* and *C. albicans* revealed more rapid evolution of resistance, lesser fitness trade-off for drug resistance, and longer-term acquisition of resistance in *C. auris* compared to *C. albicans*. Research on environmental adaptations indicated preferential colonization of skin, deeper tissue, and formation of aggressive skin biofilms by *C. auris* that prevent death in nosocomial environments or by disinfectant products. These factors suggest that *C. auris* carries a higher risk

compared to non-auris *Candida* spp. to hospitals, and that future therapeutic and preventative protocols must be re-evaluated in the context of highly-resistant *C. auris*.

Abstract Name: Wildfire Smoke Exposure Altered Hippocampal Mitochondrial Dynamics and Corresponding Blood Biomarker Generation

Wildfire smoke (WFS) exposure has been associated with increased dementia in susceptible regions, raising concern that WFS is an environmental modifier of Alzheimer's disease and related dementia (ADRD) pathogenesis. However, the impact of WFS on neurological pathologies remains largely unknown. Thus, there is a need to assess neuropathogenic processes using modeled WFS exposure whilst developing translatable biomarkers to assess corresponding pathology in at-risk populations. In collaboration with the University of New Mexico, a mouse (C57BL/6) hippocampal neuroproteomic and serum peptidomic dataset was analyzed following 3 weeks of 4 hrs/day 100 µg/m³ California wildfire particulate. In the neuroproteome, 3715 proteins were identified, of which 1264 (34.02%) were significantly responsive to WFS relative to filtered air (FA). Responsive proteins displayed functional enrichment in loss of synaptic connectivity (312), abnormal mitochondrial dynamics (222), and cell junctions (344). Early-stage neurodegenerative conditions are associated with perturbed energetics and synaptic dysfunction. Proteomics identified loss of Cend1 & Drp1, key regulators of bioenergetic dynamics in neurons. Immunofluorescence microscopy confirmed acute loss of Drp1 post-WFS in input/output regions of the hippocampus, independent of mitochondrial density control. Drp1 loss was validated in vitro by exposing cerebrovascular endothelial cells to blood from WFS-exposed mice. WFS-exposed blood demonstrated circulating bioactivity modulating endothelial tight junctions, the blood-brain barrier, and Drp1. Biomarker probing of serum peptidomics identified 389 peptides, of which 160 (41.1%) were significantly responsive to WFS, 126 (78.8%) were brain-expressed, and 15 (3.86%) were brain-enriched. Brain-expressed peptides showed enrichment in endothelial vasculature regulation, while brain-enriched peptides were associated with synaptic regulation. Identification of Cend1 & Drp1 in serum portends relevance as biomarkers of altered mitochondrial bioenergetics. Overall, WFS exposure alters circulating factors that impact the blood-brain barrier, impair mitochondrial fission, and reveal that peptides shed into blood may provide putative biomarkers with translational potential for human assays.

Abstract Name: Restoring Intestinal Barrier Integrity Through Altering a Tight Junction Protein Leads to a Reversal of Aging Phenotypes in Drosophila

Intestinal barrier dysfunction, where the gut becomes leaky, is one of the hallmarks of aging observed across species from Drosophila to humans. Understanding how the loss of barrier function may impact aging phenotypes and whether these phenotypes can be reversed are questions that may lead to a better understanding of diseases of aging. This study utilizes Snakeskin (Ssk), a tight junction equivalent protein, which is important for preventing gut permeability between adjacent gut epithelial cells. The fruit fly, *Drosophila melanogaster*, is used in this research because of the short lifespan and easy genetic manipulation tools, where Ssk protein levels can be altered specifically in the gut by placing the flies on food that drives Ssk RNAi knockdown or overexpression and can be restored by placing flies on control food. The Smurf assay is used to monitor intestinal permeability through feeding flies a blue dye to check for a leaky gut. Ssk levels have previously been shown to naturally decline in the aging fly gut, which correlates directly with intestinal barrier failure. Furthermore, when Ssk is genetically lowered in young flies, they age prematurely, revealing numerous hallmarks of aging, including an increase in inflammation and metabolic dysfunction and a drastically reduced lifespan. This work investigates how changes in the gut impact mitochondria in the brain and thorax muscles of flies and whether strengthening the gut can delay these phenotypes. Mitochondria dysfunction is a known marker of aging and these studies are attempting to understand the impact of gut barrier dysfunction on brain and muscle aging phenotypes. These experiments are attempting to understand whether the breakdown of tight junctions are a primary cause of age-related systemic decline and may suggest that therapeutic strategies targeting these proteins may be a viable route to slow down the aging process.

Abstract Name: “From Reflexes to Reasoning”: Hierarchical Emergence of Cognition in Multi-level Agent-Based System

Understanding how consciousness emerges from neural organization remains one of science’s most profound challenges. While Chalmers’ hard problem suggests that subjective experience may resist full reduction, we can still investigate the organizational conditions that consciousness theories propose as prerequisites for experience. This project models a multi-level agent-based system inspired by biological organization, built as a four-step hierarchy — reflexive sensory-motor reactions, coordinated group behavior, perceptual awareness through information aggregation, and simple decision-making through evaluating alternatives — where each level is composed of entities from the level below. To mirror evolutionary pressures, the simulation is designed as a competitive “battlefield” environment in which agents must secure resources, avoid threats, and outcompete others to survive and reproduce. Swarm intelligence and genetic algorithms simulate the adaptive processes that shape populations under these constraints. The central hypothesis is that this hierarchical structure acts as a computational scaffold, enabling higher-level abilities to emerge only when lower-level organization is in place. Using simple metrics such as survival ratio across generations, the model evaluates whether agents with more complex hierarchical organization consistently outperform those with simpler architectures. This work shows how agent-based modeling can be used to explore organizational principles drawn from theories of consciousness within a biologically inspired, competition-driven setting.

Abstract Name: The Government is Doing WHAT?: "Websploring" Perspectives on Cloning, Conspiracy, and the More-Than-Human World

This project critically examines online narratives about human and more-than-human cloning, with a focus on the spread of misinformation, radicalization, conspiracies, and their dangerous impact. At first glance, discussions about human vs more-than-human cloning differ significantly. Human cloning is commonly considered morally objectionable, with supporters often forming part of controversial communities. In contrast, more-than-human cloning frequently sparks curiosity and, in some contexts, is encouraged. It is viewed not as an "act against God" but as a testament to human intelligence and dominance. This difference in responses raises many questions: Why are responses so dissimilar? How does online discourse drive these reactions? And can these distinctions--these different understandings of personhood and "life"--reinforce or perpetuate ideologies that cause harm? To answer these questions, I examine academic explorations of cloning and compare them with ones found all across the digital sphere--from social sites such as Reddit, X (formerly known as Twitter), and 4chan, to YouTube comment sections. Using a digital, "websplorer" approach, I analyze different perspectives on cloning, ranging from the "manosphere"-- interconnected misogynist online communities, scientism, and how they relate to the more-than-human. After a critical interrogation of these perspectives, I invite the user to consider an alternative, perhaps more ethical, approach to discussing cloning, one that does not reinforce heteronormativity, human exceptionalism, or pro-eugenic views. This alternative approach includes an exploration and critique of the Western concept of "personhood" and its limitations regarding cloned life, human and more-than-human.

Abstract Name: Highways and Hardships: The Indianapolis Recorder's Role in Fighting Urban Segregation

During the mid-twentieth century, infrastructure projects across the United States disproportionately targeted Black neighborhoods for demolition under the guise of urban renewal. In Indianapolis, Indiana, the construction of Interstate 65 between the 1950s and early 1970s displaced hundreds of Black residents on the city's northside and permanently altered long-standing community networks. While scholars have examined discriminatory planning practices and the national dimensions of environmental racism, few have analyzed how Black newspapers documented and shaped resistance to these policies. My research offers a microhistory of the Indianapolis Recorder, one of the nation's oldest Black newspapers, and its coverage of the I-65 project from 1954 to 1973. Using articles, photographs, and editorials from the Indianapolis Recorder alongside secondary sources on urban planning and racial segregation, this project evaluates how the newspaper informed residents, exposed discriminatory practices, and mobilized local activism. The Indianapolis Recorder reported early warnings about displacement, highlighted the efforts of resistance and activist organizations such as the Hubbard Center Civic League and Homes Before Highways, and linked Indianapolis activists to broader civil rights networks and leaders, including Dr. Martin Luther King Jr. The Indianapolis Recorder played an essential role in resistance efforts to urban renewal in Indianapolis during the

late 1960s and early 1970s. The newspaper provided necessary coverage of the displacement caused by the construction of Interstate 65 and amplified the voices of organizations and activists fighting the project.

Abstract Name: Modeling the Transport of Forever Chemicals in the Arctic Ocean

Pollution affects every ecosystem on the planet, from the warmest tropical coastlines to the most remote polar seas, where contaminants can accumulate despite limited local human activity. With Arctic shipping routes expected to expand as sea ice declines due to climate change, the introduction and redistribution of pollutants in these fragile ecosystems is likely to accelerate. Yet little is currently known about the baseline contamination of the Arctic, making computational modeling a critical tool for exploring how pollutants may enter, move through, and accumulate within the region. This project, building on an earlier simulation of global ocean behavior, extends this framework to a dedicated Arctic domain to examine how the forever chemicals, Per- and polyfluoroalkyl substances (PFAS), may be transported into and across the region. Using the Massachusetts Institute of Technology's General Circulation Model (MITgcm) and Arctic PFAS samples collected by researchers at my university this September, I will build a baseline of observed PFAS concentrations and use the circulation model to help explain the ocean pathways that may contribute to their presence. By April, this project will provide predicted transport pathways, areas of potential pollutant buildup, and a reusable Arctic circulation simulation that can support future contaminant studies and field sampling efforts. These results will provide new context for understanding how contaminants might reach high-latitude environments and will support future efforts to expand Arctic pollution monitoring. At NCUR, I will present the modeling framework, the initial PFAS baseline, and insights from the Arctic circulation simulations.

Abstract Name: Winery Waste, Better Goats? Testing Fermented Grape Pomace

Grape pomace (GP), the primary byproduct of the winery industry, can be utilized as a sustainable feed resource to improve ruminant health and performance. GP is rich in nutrients like fiber, residual oil, and polyphenols, with the latter known for its antioxidative properties. Fermentation or ensiling of GP can reduce anti-nutritional factors, improve protein and carbohydrate availability, and enhance ruminal fermentability, suggesting potential benefits for growth performance when included at moderate dietary levels. The objective of this study is to determine the effect of dietary fermented GP on growth performance in healthy growing bucks. We hypothesize that 10% fermented GP will not impair feed intake and will maintain or improve average daily feed intake (ADFI), final body weight, and feed conversion ratio (FCR) relative to the control. A feeding trial will be conducted using a randomized block design with 10 growing bucks fed a control diet and 10 growing bucks fed a pelleted diet containing 10% fermented GP (dry matter basis) for 42 days. Bucks body weight will be measured on days 1, 15, 29, and 43 of the feeding trial periods, and ADFI, average daily

gain, and FCR will be calculated accordingly. Data will be analyzed using the generalized linear model procedure (PROC GLM) of SAS for analysis of variance (ANOVA) of the treatment effect. $P \leq 0.05$ will be considered significant. It is expected that fermented GP supplement will enhance the ADFI, final body weight, and feed efficiency of growing bucks. Also, this study will be the first to explore the potential sustainability of fermented GP in goat production. Findings will inform undergraduate research and practical recommendations for valorizing winery by-products in small-ruminant production while contributing to circular agricultural systems.

Abstract Name: The Apocalyptic Sublime and the Integration of Secular Anxieties into Biblical Apocalyptic Art

Throughout early Western Europe, apocalyptic art was strictly related to the Biblical Apocalypse and was used as a vessel to channel related fears of the end of the world through God's wrath. However, as the worldly elements of human culture have progressed, apocalyptic art has become integrated with secular iconography and associated anxieties as a motivation for its creation. This transition of depicting religious fears to the secular is first seen in 19th-century apocalyptic art of the British romantic sublime movement, with drastic political, economic, and cultural change throughout Europe influencing apprehensions. While apocalyptic scenes from the Bible still prevailed as the mode of how the apocalypse was perceived in art, there was an increasing inclusion of secular iconography that exemplified how people were no longer fearful of just God's fury; now, it was the consequences of human action that would bring upon the world's downfall. This beginning of this transitional period is first seen in J.M.W. Turner's *The Deluge*, with the deliberate inclusion of an African slave catching a fallen European woman during the storm, acting as commentary to the burgeoning calls for abolition in Britain and the great debate that surrounded it, in particular by the controlling white populous who feared the loss of power and control. This idea is further exemplified in the work of John Martin, who speaks to anxieties regarding the growing urban environment and industrialization, and Sir Francis Danby, who, in a similar manner to Turner, depicts a slave broken free of his chains and standing above a fallen white crowd. This intermediate mixing of religious and secular depictions in apocalyptic art were increasingly popularized and influential in the adaptation of how the masses perceived both cultural change and the felt associated anxieties of the unknown and, consequently, the end of the world.

Abstract Name: Dose Effects of Nitrogen Fertilizer on Amino Acid Composition in Basil

From the research that was done over the summer, the purpose of the investigation was to discover how does different doses of nitrogen fertilizers affect the amino acid composition in basil? To provide context for the research, amino acids need to have the element, nitrogen, present in order to be produced. In addition, plants are known to thrive best with the nutrients Nitrogen, Phosphate, and Phosphorous (NPK). Therefore, this experiment is to see if the amount of nitrogen, in the form of fertilizer, would influence the types and amounts

of amino acids present in the plants, specifically basil as well as, to find out if there are any physical effects on said plants. For the standard data, a balanced 10:10:10 NPK fertilizer was used and for all sets of samples the same amount of sun and water was distributed. That way, there can be a guarantee that any results were due to the amount of nitrogen provided. When carrying out this experiment, the LC method, or the High-Performance Liquid Chromatography (HPLC), and QuEChERS method were used. The HPLC method is where high pressure is applied to move the sample, allowing for a faster and more efficient separation of non-volatile (which is easily soluble in the liquid mobile phase, in the HPLC, due to low vapor pressure and a high boiling point) and polar compounds (molecules with an unequal distribution of electrons). The separated compounds are then detected, identified, and quantified. The QuEChERS method is a Quick, Easy, Cheap, Effective, Rugged, and Safe technique for preparing samples for analysis of pesticide residues and other contaminants in food and environmental samples. The final conclusions were that the plant sets with the most amount of nitrogen added had the most different types of amino acids discovered, as expected.

Abstract Name: A Portable Handheld VOC Emissions Tracer

Additive manufacturing processes release volatile organic compounds (VOCs), aerosols, and ultrafine particles that can accumulate in poorly ventilated environments and contribute to long-term respiratory or cardiovascular diseases. Industrial systems often include filtration or monitoring equipment, but affordable, real-time solutions are rarely available for non-industrial users such as small labs, hobbyists, and students. In this paper, a portable handheld emissions tracer is presented. The tracer system integrates multiple sensors for ultrafine particulate matter (down to 1.0 μm), total VOCs, and formaldehyde into a compact, battery-powered platform that will enable accurate and efficient data collection. The system integrates Raspberry Pi Zero 2 with the Sensirion SEN55 and a MEMS formaldehyde sensor for targeted VOC monitoring. The electrical design emphasizes efficient power management; a rechargeable lithium-ion battery with a USB-C charging module which supports roughly four hours of operation. The contribution of this paper is a low-cost, adaptable solution for environmental monitoring in maker spaces and highlights the role of electrical design in developing practical, portable instrumentation.

Abstract Name: The Dynamic Effects of Abrasive Water-Jet Machining (AWJM) on Material Integrity

Abrasive Water Jet Machining (AWJM) is a versatile non-conventional process that uses a high-velocity

water jet mixed with abrasive particles to cut almost any material without inducing thermal damage. Despite its advantages, achieving repeatable dimensional accuracy and low surface roughness is difficult because of the complex influence of process parameters such as water pressure, abrasive mass flow rate, traverse speed, standoff distance, nozzle angle, and especially machining-induced vibrations and workpiece chatter. This study focuses on the effect of operational vibrations on kerf quality, taper error, striation formation, and surface roughness in AWJM. Vibration is recognized as one of the primary causes of inconsistency in cut quality, yet its systematic measurement and correlation with surface integrity remain underexplored. A significant challenge in vibration monitoring during AWJM is the extremely short machining time and harsh wet environment, which demands robust, high-frequency data acquisition systems. In this research, only contact-type piezoelectric accelerometers with waterproof sealing mounting are employed to capture vibration signals directly from the workpiece and fixture. Sampling rates exceeding 50 kHz are used to ensure accurate representation of high-frequency transients generated by abrasive particle impacts and jet instability. The acquired time-domain signals are processed through Fast Fourier Transform (FFT) and power spectral density analysis to identify dominant frequency peaks and their amplitudes under varying cutting conditions. These experimental vibration characteristics are then correlated with measured surface roughness (Ra), kerf width variation, and taper angle. Finally, the results are validated against a theoretical vibration model that incorporates jet force fluctuations, abrasive particle momentum transfer, and dynamic response of the workpiece-fixture system. This work aims to establish clear quantitative relationships between vibration signatures and cut quality, providing practical guidelines for minimizing vibration-induced defects and improving precision in industrial AWJM operations.

Abstract Name: The War on Drugs and the Controlled Substance Act: Racial Disparities and Drug Scheduling in the United States

The Controlled Substance Act (CSA)'s inconsistent guidelines lead to the disproportionate incarceration of Black Americans. The CSA and the U.S. War on Drugs of the late 20th century have contributed to racial disparities in incarceration, particularly against Black communities and while the system remains unchanged, it may continue to reinforce punitive drug policies leading to mass incarceration of Black Americans. This comprehensive literature review used peer-reviewed academic sources to examine racially disproportionate punishment during drug offenses, the drug scheduling process, and abuse potential of scheduled drugs, with a focus on marijuana's classification as a Schedule I drug in order to understand if the CSA is a significant contributor to the disproportionate incarceration of Black Americans. This research found that despite marijuana's relatively low potential for abuse and increasing medical acceptance, marijuana remains federally criminalized, a policy stance that may be rooted more in public perception of marijuana, rather than public health evidence. This classification, coupled with mandatory minimum sentencing laws, disproportionately affects Black Americans, who face higher incarceration rates for drug offenses despite comparable or lower usage rates than white counterparts. This research argued that drug scheduling functions may act as a structural mechanism of racial control to sustain mass incarceration and economic disenfranchisement in marginalized communities and explored how marijuana's legalization/reclassification may lead to a reduction in racially biased incarceration practices.

Abstract Name: Crossing Heaven and Earth: Pilgrimage to Mountain Monasteries of Meteora as a Sacred Act

In northwestern Greece lies a sandstone formation of pillars climbing 1300 feet above the plain below. These massive stone columns were named Meteora, meaning lofty or elevated, signifying how their sheer cliffsides made access very difficult and dangerous. Despite this topographic challenge, the peaks of these pillars have been home for a community of Eastern Orthodox eremites since the 9th century. Beginning as a refuge to eremites, the political upheavals in the 13th century led them to construct monasteries for shelter from Turkish attacks upon Greece. As a defense strategy, the only access points were removable ladders, hoisting ropes, or nets. These political threats have since disappeared, and yet the monks have continued to keep the monasteries practically inaccessible. Why have they chosen such an isolated and perilous location to make their sacred dwelling? This paper explores the relationship between ascetic practices, extreme rituals, and spatial configurations to argue that architecture is not merely a background for religious practices, but what renders certain experiences possible. Monastic architecture does not provide solely a dwelling but can provide an environment for spiritual practices and define sacred space. This research draws on the distinctions between sacred and profane space as developed by Mircea Eliade and further explored by scholars such as Shelley Ashdown, who states that sacred space is not exclusive but a temporal paradox. To illustrate how the sacred is constructed, this research also engages themes of liminality and spirituality through the works of Victor Turner and Rudolf Otto. By examining the monasteries through the lens of these scholarly works, this paper shows how the journey to access the monasteries of the Meteora mountains can blur the boundaries between profane and sacred space and encourage a sense of humility for life threatened with extinction.

Abstract Name: The Mystery of Leah Buff Frankel: Reclaiming the Voices of Queer Jewish Women in the Early 20th Century

Leah Buff was born into the Buff family at the turn of the 20th century. As the youngest daughter of six children, there was household pressure to fall into line and uphold the reputation the Buffs coveted in their small rural town of Charleston, West Virginia. Digging into her life and death, a myriad of questions arose as to whether or not she was expected to uphold an image that was not truly her. A general consensus was struck when presented to the team: there was more to Leah's story than at face value. Through genealogical and archival research, we stumbled upon a New York Times article detailing Leah's mysterious passing that made nationwide news. Just three days after her marriage to childhood sweetheart Charles Frankel, Leah plummeted from a hallway window of the prestigious Hotel Edison in New York City while on their honeymoon. At only 35, Leah's life ended at what should have been the start of her next chapter. However, the most striking detail of her demise came at the end of the article: the mention of a letter Leah received from her older sister, Emma, the matriarch of the family. Emma's final words to her sister read: "I have told the girls of your marriage, and they suspect nothing of your illness." These words raised a lot of questions. Why did Leah and Charles wait so long to get married? What illness was she stricken with, and why did the threat of public exposure push her to suicide? The swirl of family rumors that surrounded her also raised some lavender flags; a fear of sex, the importance of appearance to the family, and the social conservatism of the time led me to the notion that Leah did not have the words to describe her identity fully.

Abstract Name: Assessing the Impact of Nitrogen and Phosphate Fertilizers on the Growth of *Raphanus sativus* (Cherry Belle Radishes) in Simulated Martian Regolith

As science advances and humanity prepares for the possibility of sustaining life on Mars, developing reliable methods of food production becomes essential. However, cultivating crops in Martian soil remains challenging because Martian regolith lacks organic matter and many of the essential nutrients present in Earth's topsoil. This research, conducted as part of the Fall 2024 NASA Plant the Moon/Mars Challenge, evaluated how nitrogen- and phosphorus-based fertilizers influence the growth of *Raphanus sativus* (Cherry Belle radishes) in simulated Martian regolith. Control groups consisted of 100% Earth topsoil and 100% Martian regolith, while treatment groups used mixtures of simulated regolith, topsoil, and perlite. Treatments were amended with either nitrogen-rich fertilizers (worm castings, urea) or phosphorus-rich fertilizers (bone meal, superphosphate) to improve the nutrient profile of the regolith. Plants were grown indoors under controlled laboratory conditions, with pH, electrical conductivity, plant height, and leaf development measured weekly. Results showed successful radish growth in 100% topsoil and in the worm-casting-amended soils, but no growth occurred in the 100% regolith samples or in the phosphorus-amended treatments. Although worm castings promoted leafy growth, radish bulbs did not form, and the roots remained shallow and thin. These findings suggest that Martian regolith requires enrichment with organic material to support plant development, and that additional amendments such as microbial inoculants may be necessary to enhance nutrient uptake and encourage full root and bulb formation. Overall, this study provides useful insights into strategies for improving crop production in Martian regolith and contributes to ongoing efforts to develop sustainable food systems for long-duration Mars missions.

Abstract Name: The relationship between cardiovascular risk factors and cognitive and sensorimotor outcomes after stroke

Introduction: Cardiovascular risk factors like diabetes mellitus type II, hypertension, hyperlipidemia, and obesity are increasing in prevalence worldwide and have been shown to contribute to stroke risk and severity. While the relationship between these comorbidities and cognitive decline has been widely studied, their impact on cognitive and sensorimotor outcomes post-stroke remains less researched. Understanding how these comorbidities can affect stroke recovery is crucial to creating tailored post-stroke rehabilitation plans.

We hypothesized that stroke survivors with diabetes, hypertension, hyperlipidemia, or obesity at the time of their stroke would have worse cognitive and sensorimotor test scores than those without these comorbidities. Methods: Participant data (n = 44) was drawn from a multisite study. Stroke lesion volume was ascertained using 3D T1-weighted brain MRIs. Mild cognitive impairment was measured using the Montreal Cognitive Assessment (MoCA) and sensorimotor impairment was assessed using the Fugl-Meyer Upper Extremity Assessment (FMUE) and the Action Research Arm Test (ARAT). Data used was collected at baseline (within 22.11±8.5 days post-stroke). Mixed effects models were used to assess the association of diabetes, hypertension, obesity, and hyperlipidemia with cognitive and sensorimotor test outcomes and stroke lesion volume. The models were adjusted for age, sex, race, intracranial volume, and lesion volume, with site of data collection as a random effect. Results: Among the models tested, two demonstrated statistical significance. We found that diabetes at the time of stroke was associated with having greater stroke lesion volume ($\beta = 0.92$, $p = 0.01$) while hypertension was associated with lower FMUE scores ($\beta = -19.79$, $p = 0.03$). Conclusion: Cardiovascular risk factors such as diabetes and hypertension may contribute to worse post-stroke outcomes which demonstrates the need to consider comorbid conditions in treatment models and rehabilitation planning. This highlights the importance of continued research in how common comorbid conditions impact post-stroke recovery.

Abstract Name: Public Opinion, Immigration, and the News: The Weight People Put on the Media

My research question is: Does the media's depiction of immigrants/immigration impact the public's opinion on the topic? This research will examine how people react to the news they consume and what role the news media plays in their opinion on immigration. The presentation of a topic using curated language changes based on who is doing the reporting. Prior research shows that based on the media's word choice, use of images, and efforts to evoke emotion, public opinion can be swayed one way or another. People also form their opinion based on personal experiences. Taking into account how people make sense of political information, the public can also choose what information to take on as a part of their personal beliefs. I will conduct 15 semi-structured interviews from college students. Participants will be asked questions based on their reactions to the news on immigration, whether the news they engage with aligns with their opinion, and what they do when it doesn't. They will also be asked questions about alternative news sources and if their opinions have changed based on consumption of media. Participants will scan a QR code and fill in an interest form that contains some questions about their name, contact information, and availability. Based on the general decrease of young people consuming traditional media, I predict participants will place more weight on their personal experiences and alternative media sources to develop their opinion on immigration.

Abstract Name: VariantBench: A Framework for Evaluating LLMs on Justifications for Genetic Variant Interpretation

Accurate classification in high-stakes domains requires not only correct predictions but also transparent and traceable reasoning. We illustrate this need in clinical genomics and present VariantBench, a reproducible benchmark and scoring harness that evaluates both final American College of Medical Genetics and Genomics and Association for Molecular Pathology (ACMG and AMP) labels and criterion-level reasoning fidelity for missense single-nucleotide variants (SNVs). Each case pairs a variant with deterministic, machine-readable evidence aligned to five commonly used criteria (PM2, PP3, PS1, BS1, BA1), enabling consistent evaluation of large language models (LLMs). Unlike prior work that reports only final labels, our framework scores the correctness and faithfulness of per-criterion justifications against numeric evidence. On a balanced 100-variant set, Gemini 2.5 Flash and GPT-4o outperform Claude 3 Opus in label accuracy and criterion detection, and both models improve substantially when the decisive PS1 cue is provided explicitly. Error analyses show that models reliably use population-frequency cues yet underuse high-impact rules unless the evidence is unambiguous. VariantBench provides a foundation for tracking such improvements and for comparing prompting, calibration, and aggregation strategies in genomics and other rule-governed, safety-critical settings.

Abstract Name: Synthesizing a Central Resource for Congenital Nephrotic Syndrome

Congenital nephrotic syndrome (CNS) is a rare form of kidney disease occurring within three months of birth, affecting one to three in every 100,000 newborns in the US. The prognosis for CNS is very poor, quickly developing into end-stage renal disease by age three. Kidney transplants are the only curative treatment for CNS; it is important to find other ways to treat CNS and manage its symptoms, especially the heavy proteinuria present in all patients. Research indicates that the main cause of CNS are genetic mutations, specifically mutations causing malformations in the podocyte slit diaphragm. This thesis contributes to ongoing CNS research by synthesizing a comprehensive review of CNS, providing a clear understanding of the disease's pathophysiology, the role of genetic mutations, and currently available treatments. By combining these areas through analysis of various literature works, this thesis identifies research gaps and potential areas for further research, serving as a comprehensive resource for future CNS studies.

Abstract Name: Improving Fine-Grained Emotion Recognition with Contrastive Learning

Understanding subtle emotional cues in text is important for designing AI systems that can support healthy communication and human well-being. While traditional classification approaches using models such as BERT and RoBERTa perform well on basic sentiment tasks, they struggle when emotions become more nuanced or when the number of emotion categories increases. Recent work has proposed ordinal label schemes for emotion classification, but performance remains inconsistent and these schemes are rigid and require manual construction. In this work, we compare a contrastive learning approach to both standard

classification and ordinal label encodings across emotion subsets spanning 2 to 27 classes. We find that contrastive learning produces the strongest performance and results in fewer severe misclassifications. Further, we find a large percentage of misclassified examples appeared close to semantically related emotions in the embedding space, indicating that the model still captured useful emotional information. These results show that contrastive learning can serve as a flexible and reliable framework for emotion recognition, especially when dealing with complex or overlapping emotional categories. This work lays the foundation for a follow-up study in which these emotion embedding models will be used to analyze the emotional tone of social media content. The goal of the larger project is to understand how emotional exposure affects mental well-being and to support future tools for mental-health monitoring.

Abstract Name: The Catamount Center for Entrepreneurship and Innovation

The project explores the development of the Catamount Center for Entrepreneurship and Innovation, a proposed interdisciplinary hub designed to strengthen creativity, collaboration, and well-being among students, faculty, and the local community. The work investigates how intentional environmental design can support innovation by drawing on two research frameworks: Biophilia, which examines the benefits of human connection to natural systems, and Person–Environment Fit Theory, which emphasizes the importance of aligning individual needs with the spaces they occupy. Using these foundations, the project evaluates how a well-designed environment can enhance idea generation, problem-solving, and team-based learning across all majors. This center aims to address a current gap at Western Carolina University. Existing innovation spaces on campus, such as the Rapid Center, the Technology Commons 3DU Makerspace, and the College of Business Innovation Center, offer valuable resources but remain limited by inconsistent accessibility, visibility, and inclusiveness. The Catamount Center proposes to unify these strengths into a single, widely accessible location where users can develop ideas, launch ventures, and engage in hands-on experimentation with tools like laser cutters, 3D printers, business equipment, and industry-standard software. The center would also serve as a bridge between the university and the local entrepreneurial community, creating opportunities for mentorship, skill development, and economic growth. Although still in the research phase, the project will advance into schematic and spatial design by early 2026, informed by case studies of existing university innovation centers and their regional impact. By examining how purposeful design can cultivate innovation in a rural context, this project provides insight into how universities can expand interdisciplinary learning, support new venture creation, and strengthen community engagement through a shared, well-designed innovation environment.

Abstract Name: Analyzing Cybersecurity Data Breaches Across North Carolina Healthcare Providers: 2016-2024

Healthcare remains one of the industries most affected by data breaches driven by evolving attack vectors, third-party vendor ecosystem, and uneven cybersecurity capacity. While national research has documented where breaches occur and which sectors are most affected, comparatively little work has examined breach patterns at the state level in a way that can inform local decision-making. This study addresses that gap by asking: what trends characterize reportable healthcare data breaches in North Carolina from 2016 to 2024, and how do breach type, breach location, and timing relate to breach magnitude (number of individuals affected)? Using the U.S. Department of Health and Human Services Office for Civil Rights (HHS OCR) Breach Portal, we will extract all incidents that meet the federal reporting threshold (breaches affecting 500+ individuals) and filter the records to North Carolina for 2016–2024. The analysis will include data cleaning and variable standardization, followed by descriptive statistics and visualizations to summarize annual frequency, affected individuals, and distributions across breach types and locations (e.g., hacking/IT incidents; network servers). To assess change over time and predictors of breach magnitude, we will conduct regression analyses using year and breach characteristics as independent variables and breach magnitude as the primary outcome. We expect to identify growth in breaches associated with hacking and networked systems and to detect time-based clustering that can guide healthcare management. Findings will be discussed in the context of practical cybersecurity planning and policy—highlighting priority control areas for North Carolina healthcare organizations to better protect patient and operational data.

Abstract Name: Comparative Effects of Estrone and 17 β -Estradiol on Arc Expression in SH-SY5Y Neuroblastoma: Implications for Postmenopausal Neuroprotection and Alzheimer's Risk

17 β -estradiol (E2) is the primary form of estrogen in the female body, both in its high concentrations and its strong binding affinity for estrogen receptors. While estrone (E1) exists alongside E2 premenopause, it exists in much lower concentrations, having weaker binding affinity to similar receptors. As women undergo menopause, E2 production drops by 98% while E1 only drops 70%, leaving E1 as the predominant estrogen postmenopause. Although estrogens broadly exhibit neuroprotective effects, most research has focused on E2, leaving E1's role in the brain comparatively understudied. This gap is notable, as postmenopausal women have approximately twice the risk of developing neurodegenerative diseases such as Alzheimer's disease (AD) compared with men, a disparity often attributed to declining estrogen levels. Yet despite E1 becoming the predominant estrogen during this period, its potential contribution to postmenopausal AD remains largely unexplored. Activity-regulated cytoskeleton-associated protein (Arc) is a protein localized within the hippocampus of the brain and is critical for learning and long-term memory, where its dysfunction has been associated with the development of neurodegenerative diseases such as AD. Research in this field is limited, with current studies validating only E2 of being capable of Arc protein expression. This study aims to apply current knowledge on E2-Arc relationships to comparatively explore E1's ability to induce Arc expression. To accomplish this, proteins were extracted from SH-SY5Y neuroblastoma cells treated with 10nM of E1 or E2 and normalized using bicinchoninic acid assays. SDS-PAGE was used to quantify Arc expression with respect to β -actin loading controls. The dose-dependent nature of Arc expression is currently being explored through similar experimentation at 10, 50, 100, 150, and 200nM E1 or E2. Current data suggests E1 is capable of inducing Arc expression similar to E2, providing a framework for subsequent investigations into the estrogen dynamics underlying postmenopausal neurodegeneration.

Abstract Name: LAWS against the Laws: Reassessing Proportionality in International Humanitarian Law

As artificial intelligence begins to embed itself in modern warfare, many nations are grappling with whether usage of Lethal Autonomous Weapon Systems (LAWS) can comply with current Laws of War. While LAWS are significantly improving their target distinction, they remain expressly not able to meet proportionality requirements under Article 51 of Additional Protocol 1, because proportionality demands meaningful, moral human input prior to the use of lethal weapons. In addressing this ambiguity, I argue that the international community must either clarify the principle of proportionality requiring adequate human input or generate a new set of principles in relation to Artificial Intelligence. Some disagree, instead proffering that International Humanitarian Law (IHL) already performs the key task of analyzing specific judgment and regulations to LAWS. However, these claims fundamentally fail to address that implicit reliance of proportionality has historically been performed with human quantitative judgement. My approach is that reframing the proportionality standard or generating new specific principles of IHL will ensure accountability and accommodate for future advancements in AI. This research will deeply analyze international perspectives on the degree of human judgement required to meet current legal thresholds. Humanitarian protections and technological process have to match each other to avoid miscalculation, civilian casualties, and losing meaning in the art of war. A survey of scholarly literature indicates that this subject has not been addressed. Ultimately, this paper argues that Artificial Intelligence fails to meet the analytical threshold of weighing the loss in civilian life to any discrete and concrete military advantage gained, therefore the international community must adopt new legal principles to account for this discrepancy.

Abstract Name: Guardians of Democracies: Prevention of African Violent Overthrows with the Judiciary

After the independence of Francophone African states, the French left the power of governance to the newly founded African states, yet the impact of French colonization led to fierce power struggles between tribes and communities among these states. According to Our World in Data, of the two million deaths caused by armed conflicts in Africa, 88% were the result of conflicts relating to coups d'états. This paper will argue that constitutional provisions that legitimize the Supreme Court of the land help prevent violent overthrows of preestablished governments in Francophone Africa. It will analyze recent coups in several Francophone African countries, specifically Mali, Burkina Faso, and Niger, and evaluate the extent to which these overthrows stem from systemic governance failures rather than personal disputes among political rivals. Finally, this research will compare these cases to a successful democratic state, Benin, to illustrate how strong institutions and courts can prevent violent seizures of power. The respect, legitimacy, and implementation of the courts in relation to the core beliefs of the state's Constitution strongly influence peace and internal policies. Judicial legitimacy is a significant factor in determining whether a nation can prevent coups because it provides a foundation of respect for constitutional principles. The implications of these findings will shift the focus in Africa from a disdain for democracy to a more legitimized democratic system with an enforceable and genuine judiciary that is not hesitant to check the powers of other branches. By foregrounding the role of constitutional courts in coup prevention, this research offers a novel analytical angle not previously developed in comparative studies of Francophone Africa. Ultimately, this research argues that the strength and legitimacy of a nation's constitutional court serve as the most decisive factor in preventing violent overthrows in Francophone Africa.

Abstract Name: Exploring Teacher Preferences and Student Engagement: In-Person vs. Screen-Based Read-Alouds in Literacy Education

This project examines how teachers prefer to share read-alouds with their students and what influences those choices. Specifically, it investigates whether teachers prefer reading aloud in person or using a screen-based format, and how each approach relates to student engagement. Understanding these preferences can inform how educators design meaningful literacy experiences that keep students focused, involved, and connected during instruction. Since the COVID-19 pandemic, technology has played a larger role in classrooms, and many teachers have incorporated digital tools into their instruction. However, there has been little research connecting teachers' personal preferences with what actually happens during these read-alouds in the classroom. This study seeks to address that gap by combining teacher perspectives with classroom observations. Two elementary teachers are participating in the study. Each completed a survey designed by the researcher to share their experiences with both in-person and screen-based read-alouds, how they felt students responded, and which method they preferred. The researcher then visited each classroom to observe both types of read-alouds, taking detailed notes about how students paid attention, participated, and interacted. These observation notes and survey responses are currently being analyzed to explore how teacher perceptions align with observed patterns of student engagement across both formats. Data analysis is ongoing, and results will be interpreted in relation to teachers' decision-making about read-aloud delivery methods and the broader goal of supporting student engagement in diverse instructional settings. This study aims to contribute to a better understanding of how multimodal literacy practices can be used intentionally to promote student engagement and participation in today's classrooms.

Abstract Name: Advancing Raman spectroscopy of micro- and nanoplastics through optical and acoustic trapping

Raman spectroscopy is a powerful technique for identifying the molecular composition of samples. However, analyzing nanometer- to millimeter-sized particles or individual living cells requires stable confinement during measurement. This study focuses on implementing optical trapping and combined optical–acoustic trapping for the contactless manipulation of micro- and nanoplastics for Raman characterization. Optical trapping employs a tightly focused laser beam under a microscope to hold microplastic particles during analysis. While effective for individual microscale objects, the Raman signal weakens significantly as particle size decreases. To address this limitation, we integrated optical–acoustic trapping with Raman spectroscopy to study nanoparticles in suspension. Acoustic standing waves generated by paired ultrasonic transducers provide stable confinement of particles, while the focused laser enables both optical trapping and Raman excitation. Over time, the Raman excitation laser partially evaporates residual liquid, producing a more

concentrated nanoplastics sample that enhances signal detection. These approaches have been applied to lab-generated microplastics, ocean-collected samples, and commercially purchased nanoparticles, demonstrating their versatility for environmental and biomedical studies.

Abstract Name: An Integrative Antigen Discovery Pipeline to Accelerate Vaccine Development

The world's two currently approved malaria vaccines do not provide long-lasting sterile protection, leaving millions at risk of disease and death. Current vaccines rely on antibodies that target a parasite protein with high phenotypic diversity, contributing to limited durability. In contrast, the highly conserved ribosomal proteins (RPs) are a promising class of vaccine antigens that show little sequence diversity, are expressed at all stages of the parasite's life, and can induce sterile protection in small animal models. Despite these potential advantages, only a small subset of the 70-80 RPs encoded by *Plasmodium* have been experimentally evaluated in vaccine studies. The ability to evaluate proteins as vaccine candidates is impeded by a bottleneck caused by a lack of cost-efficient, high-throughput screening methods. Here, we demonstrate a novel pipeline that integrates computational predictions with *ex vivo* assays to accelerate antigen discovery in a cost-effective and biologically relevant manner. In Aim 1, we will use multiple *in silico* models to predict the immunogenicity of RP-derived peptides based on cellular processing and human genetic diversity in malaria-endemic regions. Top-scoring peptides will have their reactivity to *Plasmodium*-exposed T cells measured, allowing us to identify RPs containing the most immunoreactive peptides. In Aim 2, we will construct DNA vaccines encoding the downselected RPs from Aim 1 and evaluate their immunogenicity in mice. Finally, we will evaluate CD4⁺- and CD8⁺-mediated contributions to these RP-specific responses. We expect this study to lay the foundations for challenge experiments that reveal whether these previously uncharacterized RPs can provide sterile protection. More broadly, we anticipate that our pipeline could be scaled and applied to the full proteomes of *Plasmodium* and other infectious pathogens to streamline cost-effective identification of novel antigens and accelerate vaccine development.

Abstract Name: Investigating the Effects of a Hexylamine-Derived Compound on Cell Death in A375 and N2a Cell Lines

According to the American Cancer Society, roughly 2 million new cancer cases are expected to be diagnosed in 2025, with 618,000 of those cases resulting in death. Currently, the Food and Drug Administration (FDA)

has approved more than 300 anticancer drugs, yet cancer prognosis remains inconsistent, tissue-specific, and inversely proportional to cancer staging. Additionally, due to their high mutation rate, cancer cell lines can develop resistance to anticancer drugs over time. For this reason, it is imperative to identify new potential anticancer drugs to treat cancers that are resistant to current treatments. Herein, we demonstrate the promise of a newly synthesized drug towards anti-proliferation capacity. Our work investigated the effects of this hexylamine derivative compound on various cell lines to determine its anticancer properties. Exposure to kidney cell type, HEK293 cells, showed a decrease in MTT cell viability at a drug concentration of 30 micromolar. Conversely, fibroblastic NIH/3T3 and melanoma SK-MEL-28 cell lines showed no change in response to drug exposure. The mechanisms by which the hexylamine derivative causes cell death are still unknown, but may include apoptosis, necrosis, or autophagy. Therefore, this study aims to examine the molecular mechanisms responsible for hexylamine-induced cell death. Using two western blots, we will measure the concentrations of caspase-3 and LC3-II, which are hallmark proteins in apoptosis and autophagy. We will also investigate whether drug exposure modulates actin polymerization in neuronal N2a and glial A375 cells. Collectively, our work will generate first-of-its-kind evidence for the use of this hexylamine derivative towards anti-tumorigenic activity, highlighting its translational potential.

Abstract Name: Building a Living Biobank: Undergraduate Contributions to the VCU Kidney Transplant Prospective Registry

Kidney transplantation restores kidney function for patients with end-stage kidney disease, yet predicting long-term success remains challenging. This project utilizes the VCU Kidney Transplant Prospective Registry to identify demographic and molecular predictors of long-term allograft survival and complications. The Registry was developed to create a longitudinal, data-rich biobank that connects biospecimens with clinical outcomes. To date, 735 patients have consented to participate, with 632 having received a transplant and 103 remaining on the waitlist. Biospecimen data are available for 729 participants (99%), representing 6,552 unique samples that include 1,929 blood samples, 2,906 plasma or serum samples, and 1,717 urine samples. Among transplanted participants, most are between 50 and 69 years old, 57 percent identify as male, and 62 percent identify as Black or African American. The leading causes of kidney disease are systemic and secondary glomerular disorders, followed by inflammatory and primary glomerular diseases. Transplants have included 605 kidney and 27 kidney-pancreas recipients, with 538 organs from deceased donors and 94 from living donors. Most patients were transplanted within three months to two years after listing, although a subset waited more than five years. As undergraduate research assistants, we process and catalog biospecimens in LabNAV, link them with de-identified clinical data, and track measures such as transplant status, diagnosis, donor type, and wait time. Our work involves managing clinical research data, performing descriptive analyses, and contributing to translational science. Initial results confirm the Registry's utility in investigating ethnic and racial disparities, given its significant demographic representation. Ultimately, the biorepository provides the foundational data and specimens needed for precision medicine research to discover novel biomarkers and improve long-term patient outcomes in Virginia.

Abstract Name: Assessing the role of surface protein from segmented filamentous bacteria in adhesion to gut epithelial cells through *Bacillus subtilis* model system

Segmented filamentous bacteria (SFB) are unculturable, host-specific commensal gut microbes. In the body, SFB function as potent inducers of host adaptive and innate immune system, facilitating the destruction of pathogens. SFB prime the immune system through vesicles transporting bacterial proteins to the intestinal epithelial cells (IEC). This is enabled by intimate binding of SFB to the hosts' IECs in the ileum (small intestine). SFB initially adhere to the ileum through flagellum-mediated binding to TLR 5 receptor, but multipoint, tight binding to epithelial cells is still intriguing. Ileal IECs are protected from lumen content by mucus, which is hydrogel rich in carbohydrates. Furthermore, some cell receptors of IECs are decorated with various carbohydrates. Fucosylation of IECs is closely related to the immune function of intestinal mucosa and could be triggered by cytokine IL-22. Protein P12260 was predicted to be an SFB-unique lipoprotein on the surface of bacteria and contains carbohydrate-binding domains. We hypothesized that SFB-host binding may be mediated by protein P12260-carbohydrate interactions. This project is part of a larger laboratory project which establishes *B. subtilis* as a model bacterium for surface display of SFB proteins for their functional studies. Specifically, this project investigates binding of P12260(SFB)-expressing *B. subtilis* to fucosylated mice epithelial cells by using an adhesion assay. To induce fucosylation of mice ileal IECs in vitro, mice IL-22 was purified and added to the cell growth media. If the results of the adhesion assays with 12260-expressing *B. subtilis* and IECs show increased ileal binding compared to *B. subtilis* alone, it would suggest their potential as an improved oral vaccine delivery system.

Abstract Name: Get Your Words Off Me: Role of Aesthetic Distance in Staging Gender-Based Violence

"Her hair is all done well, and the professional make-up... I don't know, she just doesn't seem like a victim." In my conversation with the playwright Mara Nelson Greenberg, I asked what prompted her to write her extraordinary absurdist play *Do You Feel Anger?*, and she shared this story with me. As she was watching an HBO documentary "Allen v. Farrow", she caught herself subconsciously assessing Dylan Farrow and determining whether she was acting in a way that we typically expect a victim to; having realized that, Mara was able to distance herself from that process and evaluate it deeper for what it really was. From the meditation on this phenomenon *Do You Feel Anger?* came to be. It's a play that explores how we judge survivors of inter-personal violence and how their physical attributes and behaviors affect our judgement. In this paper I will explore possible approaches to the staging of the play and propose a directorial concept that can force audience members to encounter and address this phenomenon, and, hopefully, teach them more productive ways of communication with the survivors of (especially gender-based) violence.

Abstract Name: Human Mesenchymal Stem Cells as Antimicrobial Therapeutics in *Mycobacterium abscessus* and *Pseudomonas aeruginosa* Infections

Introduction: Pulmonary infections pose a major cause of morbidity and mortality in immunocompromised individuals, including patients with immunodeficiency diseases, cystic fibrosis, cancer, and aging. Despite antibiotic advancements, bacteria such as *Mycobacterium abscessus* (*M. abscessus*) and *Pseudomonas aeruginosa* (*P. aeruginosa*) continue to evolve resistance. Mesenchymal stem/stromal cells (MSCs) have anti-inflammatory and antimicrobial properties, mystifying their clinical efficacy. We hypothesize that although MSCs are antimicrobial, a specific MSC phenotype provides the best secretome potency. **Methods:** Confluent MSCs from three donors (2320, 2326, 2337) were cultured for 72 hours to generate secretomes, which were tested in vitro on 104 colony-forming units (CFUs) of *M. abscessus* and *P. aeruginosa*. *M. abscessus* cultures were incubated for 24, 42, and 48 hours, while *P. aeruginosa* cultures were incubated for 4 and 24 hours. At each point, bacterial growth was quantified through optical density OD600nm and CFU post-treatment. **Results:** MSC secretomes inhibited *M. abscessus* in a donor-dependent manner. In *M. abscessus* donor 2326 achieved the strongest reduction at 42 hours (74.5%), while 2337 and 2320 performed similarly (68–70%). All three reached near-complete inhibition (>99.5%) by 48 hours. In *P. aeruginosa*, at 24 hours, 2320 was most potent (99.6%). Donor 2337 showed moderate inhibition (66.5%), while donor 2326 unexpectedly promoted growth (–11,642%) relative to the control medium. Despite these differences, all three secretomes significantly inhibited *P. aeruginosa* ($p < 0.05$) by the culture endpoint, though inhibition varied significantly among donors and between species. **Conclusion:** These results suggest MSC-derived secretomes can serve as complementary antimicrobial agents and emphasize the need for expanded research into donor-specific variability when developing MSC-based therapeutics. **Acknowledgments:** Research reported in this review was supported by The National Center for Regenerative Medicine ENGAGE Summer Program, The Cystic Fibrosis Foundation, The Marcus Foundation, and The Bonfield Laboratory at Case Western Reserve University School of Medicine.

Abstract Name: Sex-differences in Paraspinal Muscle Quality and Response to Pain Treatments for Chronic Low Back Pain

Chronic low back pain (cLBP) remains a leading cause of disability, yet diagnostic procedures such as the medial branch block (MBB) provide only short-term analgesia and offer limited insight into neuromuscular impairments that may influence long-term outcomes. Paraspinal muscle (PSM) quality degeneration, particularly increased fat infiltration (FI) of the multifidus (MF), has been consistently associated with diminished segmental stability, reduced force-generating capacity, and compensatory movement strategies that increase spinal loading. Because sex differences in muscle morphology are well established in clinical and nonclinical populations, determining whether these differences extend to PSM quality may refine interpretation of pain presentation and early treatment response. This study investigates sex-specific patterns of MF FI and evaluates how these structural characteristics relate to functional status and immediate analgesic response to MBB in adults with cLBP. Six participants completed validated patient-reported measures of pain intensity and physical function immediately before and 30-60 minutes after the procedure.

High-resolution lumbar MRI scans were acquired at the L4/L5 vertebrae using a standardized proton density fat fraction protocol. MF cross-sectional area and fat fraction (FF) were manually segmented by trained raters using reliability-checked workflow to quantify muscle quality and left-right asymmetry. Preliminary results show that although men and women reported similar baseline pain and functional limitations, women exhibited higher MF FF, while men demonstrated greater side-to-side asymmetry. Both groups experienced clinically meaningful short-term pain reductions post-MBB, suggesting that immediate analgesic response may reflect nociceptive blockade rather than underlying neuromuscular status. These findings underscore the value of incorporating PSM quality into clinical assessment frameworks as MF degeneration may influence longer-term biomechanical recovery despite comparable early symptom relief. Ongoing analyses will determine whether sex-specific muscle characteristics predict post-procedure movement patterns and rehabilitation trajectories. This work aims to advance precision rehabilitation by informing sex-informed assessment and intervention strategies for individuals with cLBP.

Abstract Name: Machine Learning–Based Analysis of Optical Emission Spectroscopy of Cold Atmospheric Pressure Plasma Jet

Optical Emission Spectroscopy (OES) is a non-invasive diagnostic technique used to characterize plasmas by examining the light emitted from excited atomic and molecular species. In this study, spectral data were collected using an Ocean View spectrometer positioned 4–6 cm from a Cold atmospheric Pressure Plasma (CAPP) jet operating at room temperature. The OES system recorded intensity as a function of wavelength, producing detailed emission profiles of the plasma jet. Collecting high-quality OES data presents several challenges, including human and instrumental errors, fluctuations in detector response, and instability in the plasma source itself. Because the gas flow feeding the plasma jet is not perfectly constant, the emission signal exhibits time-dependent oscillations, which complicate the extraction of stable and reliable spectral features. Furthermore, CAPP jet inherently introduce temporal and spatial variations in discharge behavior, adding further uncertainty to the measured spectra. These fluctuations hinder consistent peak detection and wavelength calibration, particularly when performed manually. To address these challenges, machine learning techniques were used to enhance spectral processing and analysis. MATLAB-based algorithms enabled automated peak identification, noise reduction, and wavelength classification. Integrating AI/ML methods made the analysis more robust to variability in plasma conditions and measurement noise. Our model has significantly improved spectral line recognition, corrected oscillatory artifacts, and enabled the extraction of more reliable physical insights from complex OES datasets, demonstrating its value as an advanced tool for plasma diagnostics.

Abstract Name: Mental Freedom: Discovering and Letting Go

The current study will examine the effectiveness of the Mental Freedom (MF) coaching framework, a six-session cognitive-behavioral program grounded in William Glasser's Choice Theory/Reality Therapy (Glasser, 1998). Mental Freedom is designed to strengthen emotional resilience, enhance coping skills, and cultivate personal autonomy through a structured set of cognitive heuristics (Olver, 2024). Each session introduces a core principle: (1) Responsibility vs. Response-ability; (2) the Unconditional Trust Challenge; (3) positive and intentional self-talk; (4) reframing the subjectivity of memory; (5) distinguishing Signal vs. Source when interpreting emotional pain; and (6) recognizing life's Gifts, Lessons, Opportunities, and Wisdom (G.L.O.W.). These components collectively aim to help individuals reinterpret stressful experiences and engage in more adaptive appraisals of daily challenges. In this study, Mental Freedom-certified counselors and life coaches will administer the MF program to clients in the experimental condition, while clients in the control condition will continue receiving their provider's usual coaching or counseling modality. Before beginning the six-week intervention, all participants will complete two measures: the 14-item Scales of Psychological Well-Being (Ryff, 1989) and the Ways of Coping Questionnaire (Folkman & Lazarus, 1988). These instruments assess emotional regulation, problem-focused coping, autonomy, personal growth, and self-acceptance. Participants will complete the same measures following the program, allowing for pre-post comparisons. We expect that clients in the Mental Freedom condition will report significant improvements in well-being and coping relative to the control condition, particularly in areas emphasized by the MF framework—such as autonomy, environmental mastery, and self-acceptance. These anticipated findings would support the potential utility of Mental Freedom as an accessible coaching approach that integrates cognitive reframing, constructive self-talk, and strengthened emotional insight. Future work may explore how MF performs across diverse populations and contexts, including individuals experiencing acute stress, trauma recovery, or major life transitions.

Abstract Name: Not All Regrets Are Created Equal: Attachment Style Explains Why

Regret research suggests that individuals experience different emotional responses depending on whether a negative outcome follows from an action they took or an action they failed to take. Early findings (Kahneman & Tversky, 1982) suggest that failed actions typically evoke more intense regret than inactions. However, later work highlights the prominence of inaction regrets, especially over time (Gilovich & Medvec, 1994; Beike et al., 2009). These mixed results raise the question that individual differences may play a role in shaping regret. One promising factor is attachment style, which influences how people make decisions, interpret responsibility, and respond to negative emotional outcomes. The current study investigates whether regret intensity for actions versus inactions differs as a function of one's attachment style. Approximately 60 undergraduate students will participate. After completing an existing attachment style measure (i.e., anxiety and avoidance), participants will read brief scenarios in which a negative outcome follows either from switching their initial choice (action) or staying with it (inaction). After each scenario, participants will rate the intensity of regret they expect to feel. This scenario-based paradigm allows us to examine how decision type and attachment style interact in shaping regret evaluations. We expect to replicate the well-documented main effect of decision type: actions will elicit stronger immediate regret than inactions.

More importantly, we predict an interaction between attachment style and decision type. Individuals higher in anxious attachment—who tend to ruminate, anticipate rejection, and feel heightened responsibility—are expected to report stronger regret following failed actions. In contrast, individuals higher in avoidant attachment—who typically suppress negative emotions and minimize dependence—are expected to show little difference in regret across decision types. This study aims to clarify why people differ in the intensity of regret they experience and how relational tendencies may shape emotional reactions to negative outcomes, contributing to a more nuanced understanding of decision-making processes.

Abstract Name: Seasonal Physical Activity in ICU Survivors

Introduction: Critical illness often leads to long-term physical and functional impairments that alter quality of life after intensive care unit (ICU). Physical activity (PA) patterns influence recovery trajectories for patients recovering from ICU stay. While seasonal PA fluctuations have been observed in community-dwelling adults, differences in PA by season in ICU survivors remain unknown. Therefore, the purpose of the study was to identify seasonal PA differences in ICU survivors. **Methods:** An interim analysis of PA data in ICU survivors from a prospective longitudinal study (NCT05537298) was examined for seasonal PA trends. PA was monitored via Garmin VivoFit-4 at hospital discharge (baseline), 3 months, and 6 months after discharge. A six-minute walk test (6MWT) was administered at each visit. Seasonal mean step counts were categorized by data collection dates. A two-way analysis of variance was used to examine the effects of season and time point on mean daily step count. Pearson correlations assessed associations between 6MWT and seasonal mean step count data. **Results:** Eighty ICU survivors were included (age 57 ± 13 years; BMI 28 ± 7 kg/m²; 54% male). No significant differences in mean daily step count were identified among the seasons (Autumn, Winter, Spring, Summer) for ICU survivors across the total recovery trajectory (all time points combined) or at individual time points (baseline, 3-month, 6-month). However, there was a significant difference in daily step count between baseline and 6-month ($p=0.0007$) and 3-month and 6-month ($p=0.045$) time points. Correlations between PA and 6MWT trended weakly positively at baseline ($r=0.4$, $p=0.072$) and were moderately and weakly correlated at 3-month ($r=0.5$, $p=0.003$), and 6-month ($r=0.4$, $p=0.037$), respectively. **Conclusions:** Independent of seasonal effects, patients increased physical activity after 3 months. These findings inform future research emphasizing existing interventions and the importance of continuous PA capture to improve post-ICU patient outcomes. **Funded By:** AR081002, K23 AR079583

Abstract Name: Evaluating Ethiopian Raw Coffee as a Sustainable Reducing Agent for Cr(VI)-Contaminated Wastewater

Hexavalent chromium [Cr(VI)] is a highly toxic pollutant commonly generated by industrial activities and linked to severe health risks, including carcinogenic effects. In contrast, trivalent chromium [Cr(III)] is significantly less toxic and functions as an essential micronutrient, making the reduction of Cr(VI) to Cr(III) a practical remediation strategy. This study investigates the potential of Ethiopian raw coffee as an environmentally friendly electron donor for the reduction of Cr(VI). Raw coffee beans were ground, air-dried for 2 weeks, sieved to obtain uniform particle sizes between 0.335 and 1 mm, and mixed at a mass-to-volume ratio of 0.5 g per 20 mL with simulated wastewater containing 25 mg/L Cr(VI). Reaction samples were collected over time using a syringe attached with a luer-lock PVDF 0.22 μ m filter, and all experiments were conducted at room temperature. Cr(VI) concentrations were measured using the diphenylcarbazide colorimetric method with an Aquamate 8000 UV-Vis spectrophotometer at 540 nm. Preliminary results showed that approximately 40 percent of the initial Cr(VI) disappeared within 80 minutes in the presence of raw coffee. Additional experiments will evaluate different mass-to-volume ratios and particle sizes, and further kinetic and thermodynamic results will be presented at the conference.

Abstract Name: Impact of Calcium Channel Blockers on *Sneathia vaginalis*-Induced Ca²⁺ Influx

Sneathia vaginalis is an anaerobic gram negative streptobacillus and a component of the vaginal microbiome. It is consistently associated with negative pregnancy outcomes including amnionitis, preterm premature rupture of membranes, and preterm birth. *S. vaginalis* produces the cytopathogenic toxin A (CptA), which forms pores in the plasma membrane of human cells. The lab recently discovered that *S. vaginalis* causes rapid influx of Ca²⁺ into vaginal epithelial cells in a CptA-dependent manner. The hypothesis behind this study is that L-type and T-type calcium channel blockers prevent CptA-mediated Ca²⁺ influx. To test this hypothesis, VK2 E6/E7 vaginal keratinocytes were loaded with the calcium binding fluorophore CalbryteTM 520AM as an indicator of intracellular calcium levels. VK2 cells were pretreated with the pharmacologic calcium channel blockers nifedipine, cinnarizine, or verapamil prior to exposure to *S. vaginalis*. Fluorescence measurements were collected every minute for ten minutes to assess intracellular Ca²⁺ influx. Assays for cell viability were conducted to confirm that the concentrations of channel blockers used were not toxic to VK2 cells and to assess their effect of CptA-induced cytotoxicity. The results revealed that L/T-type calcium channel inhibitors reduce *S. vaginalis* induced Ca²⁺ influx. This suggests that Ca²⁺ influx depends upon a human calcium channel expressed on the VK2 cells rather than on the pores formed by CptA. In future work, the calcium channel/s responsible for CptA will be identified. This project contributes to our understanding of a key virulence factor of *S. vaginalis* which could ultimately promote improvements in intervention and treatment of the damage that this species can inflict upon the female reproductive tract.

Abstract Name: An Economic Analysis of Immigration Policy, Logistics Costs, and Inflation on Lettuce Prices in the U.S.

This study seeks to examine the extent to which changes in immigration policies, transportation costs, and inflation influence the fluctuation of lettuce prices in the United States over the past two decades. Previous analyses by the United States Department of Agriculture (USDA) have examined the consequences of labor shortages and increasing fuel costs, yet few have integrated immigration policies, general transportation expenses, and rising prices all in a unified framework. This paper addresses this gap by studying these variables from the year 2007 to 2024. Using monthly national-level data, from the United States Bureau of Labor Statistics (BLS), as well as additional information from the United States Citizenship and Immigration Services (USCIS) and the Department of Labor (DOL), a multivariable linear regression equation was performed, with the aim to explain the impact of labor, transportation costs, and factors such as rising costs of fertilizers, pesticides, and raw materials on lettuce prices and the broad American farming industry. Regression results revealed positive correlations between the implementation of strict immigration policies, higher farm-to-market transportation expenditures, and inflation with fluctuating lettuce prices nationwide. Findings demonstrate that the biggest impact was caused by labor shortages resulting from stricter immigration legislation. Consequently, the reduction of migrant labor led to unstable lettuce prices. As a result, farm owners had to invest greater financial resources to maintain production, which in turn drove up costs for consumers. Based on these findings, future research could focus on how trade policies and tariffs affect the prices of vegetables, given that such staples are often imported from regions with fluctuating market conditions.

Abstract Name: Designing Transfers: Supporting the Transfer Learning Process for New Wheelchair Users

Background: Each year over 500,000 people sustain a spinal cord injury (SCI) and must learn to live a new life as wheelchair users. For wheelchair users, one of the most drastic changes to daily life is learning to transfer – moving from a wheelchair to a bed, toilet, car, and other surfaces. Yet, this can be very difficult to learn. Purpose: This research investigated wheelchair user's experiences learning to transfer and supporting assistive technology. Method: Wheelchair users with spinal cord injuries and rehabilitation experts were interviewed to understand the transfer learning process. A supporting literature review and product research further informed an analysis of currently available assistive devices supporting transfer learning. Findings: Wheelchair users shared personal recollections of motivation, frustration, and challenges learning to transfer. Further, interviews with rehabilitation experts provided insight into the role of assistive devices, such as the transfer board, in supporting transfer learning during rehabilitation. Notably, all wheelchair user participants reported receiving transfer board training during rehabilitation, and 80% of wheelchair users and rehabilitation experts felt that existing transfer devices could be improved. Discussion: These findings suggest an opportunity to develop improved assistive devices to support wheelchair users learning to transfer. Contributing to this need, the present study provides research-informed design criteria for future solutions to consider. The next phase of this research will involve exploring improved transfer devices meeting these criteria. Keywords: Wheelchair Users, Wheelchair Transfers, Assistive Technology

Abstract Name: Modeling Economic Warfare: A Game Theory Analysis of the U.S.–China Trade War

The U.S.–China trade war was the most severe episode of economic confrontation in modern history, inflicting billions in losses and straining global trade. Why did the two largest economies fall into this cycle of mutual retaliation? This paper employs sequential Bayesian game theory to examine how the strategic decision-making of both actors triggered the escalating conflict. The model formalizes three variables: the tariff level (t), the probability that China responds aggressively or tactically (p), and the cost of retaliation (r). Unlike existing analyses, it operates these variables across a continuous action space, allowing precise identification of the critical escalation thresholds. Results show that China accepts low tariffs but retaliates once rates exceed 20% if politically aggressive, or 30% if economically tactical. The United States' optimal strategy depends on how it interprets China's type and how costly it expects retaliation to be. These thresholds accurately match real outcomes: China accepted the initial 10% tariff but immediately retaliated when the U.S. raised rates to 25%, revealing itself as the politically aggressive type - precisely the pattern the model predicts. The model's predictive success heightens its relevance today. The project extends the framework by recalibrating parameters using the current administration's "reciprocal tariff" schedule. The updated analysis shows what small misjudgments in beliefs or retaliation costs can again push the equilibrium from stability to open conflict, with trillion-dollar consequences for both nations. By quantifying these strategic interactions, the project links formal game theory with empirical behavior to inform more stability-oriented trade policy at a critical moment in global economic relations.

Abstract Name: Girls On Film

Girls On Film is a short video artwork depicting the slow, frantic drowning of a physically modified toy dog. The dog's discarded fur and elongated legs take it further from reality, while its squealing cries and thrashing movements force life back in; its simulated death creeps closer and closer as it lowers into its drowning pool. The work forces viewers into a position of uncomfortable voyeurism without relief, which is cut abruptly short once the dog's purpose ends and its struggle stops. In this robotic performance, Girls On Film mimics real life footage of violent and sexual exploitation from flourishing industries online. The circumstances under which these are filmed, when done as entertainment, are often in this same simplistic format featuring only a grey room and the subject of harm. To mirror this in toy form forces comparison between a human object bought for its own destruction and an inanimate children's doll, letting the audience stew in that ambiguity until the very end.

Abstract Name: Regulation of Autophagy Protein Expression in Neutrophils during *S. aureus* interaction

Staphylococcus aureus (*S. aureus*) is a gram-positive bacterium that naturally colonizes the skin and nasal passages. While often harmless, it can become a serious pathogen, causing infections with high morbidity and mortality. The growing threat of antibiotic resistance has made treatment increasingly difficult, heightening concern. To establish infection, *S. aureus* has developed various strategies to evade the human immune system, particularly targeting neutrophils—the body’s first line of defense against bacterial infections. Previous work has shown that *S. aureus* without the SaeR/S gene regulatory complex is not as virulent both in vivo and in vitro. Recent research shows that the upstream accessory genes to saeR/S (saeP and saeQ) function to negatively regulate SaeR/S-mediated virulence gene expression. We have been utilizing western blots to identify and quantify autophagy proteins LC3 and p62 (the “gold standard” for autophagy detection) in neutrophils after interacting with wildtype and mutants deficient in SaeR/S, SaeP, and SaeQ, respectively (Δ saeR/S, Δ saeP, Δ saeQ). Early experiments suggest that neutrophils that phagocytose Δ saeR/S and Δ saeQ may have more expression of these autophagy proteins. These early data indicate that autophagy may function in neutrophils more efficiently during interaction with the mutants relative to wildtype. With this work and other work ongoing, the role and impact of SaeP and SaeQ may begin to be understood during the early stages of infection. Collectively, these studies will fill clinically relevant gaps in our understanding of how *S. aureus* escapes the host immune system to advance disease.

Abstract Name: A Graph on Bumpless Pipe Dreams

Schubert polynomials were introduced in 1982 and have applications to theoretical physics and geometry. In 2018, bumpless pipe dreams (BPDs) were introduced to provide a combinatorial way of studying these polynomials. In our work, we used results from existing literature to define a graph structure on the set of BPDs for a fixed permutation. We initiate the study of this graph’s properties by investigating which graphs have cycles. We wrote code to implement these objects in SageMath, a Python-based application, and used this to generate all 409,113 graphs for small permutations. We analyzed this data to form a conjecture on which permutations have acyclic graphs, which we proved using mathematical induction.

Abstract Name: Distributed Pharmaceutical Analysis Laboratory Project

Substandard and falsified pharmaceuticals pose a significant global health threat, particularly in low- and middle-income countries where regulatory oversight is limited. The Distributed Pharmaceutical Analysis Laboratory (DPAL) provides validated chemical analysis of suspect medications collected internationally, leveraging academic institutions and citizen scientists. Virginia Wesleyan University (VWU) participated in DPAL by analyzing ceftriaxone samples collected from Kenya, Uganda, Tanzania, India, Nepal, and Malawi using high-performance liquid chromatography (HPLC). Fourteen samples were evaluated, eleven of which met the $\pm 10\%$ active pharmaceutical ingredient (API) threshold. Three samples consistently failed, and repeat analysis confirmed these deviations, indicating genuine substandard quality. Initial retention time inconsistencies were traced to degraded mobile-phase buffers, which were replaced to ensure reliable results. These validated findings contribute to DPAL's mission of improving pharmaceutical surveillance, supporting public health initiatives, and enhancing trust in drug quality in low- and middle-income countries.

Abstract Name: Designing a Community Scholars Model: Lessons from a Pilot Undergraduate Research–Community Partnership Program

Undergraduate research programs are increasingly exploring models that foreground reciprocal community engagement. This presentation shares the design and early outcomes of a pilot Community Scholars Program launched through UNC Charlotte's Office of Undergraduate Research. In this model, students are paired with community organizations that serve as mentors on research projects aligned with organizational needs. During the pilot year, two partner organizations worked with teams of two students each. Drawing on my role as OUR's associate director and as a co-mentor for the project with Love in Action Project, Inc., I will highlight key design decisions, including partner recruitment and embedded support for students and mentors. I will also describe the research guidance and professional development sessions provided to support student learning and community-engaged research skills. The presentation will focus on the decision-making processes that shaped the program's structure and mentoring approach, concluding with lessons learned and considerations for future iterations.

Abstract Name: Artificial Soil Nutrient Depletion Method for Establishing Fertilizer Application Rates

Accurate determination of fertilizer application rates requires a reliable method for generating low-nutrient or zero-nutrient soil. Over-fertilization is a significant contributor to nutrient runoff, environmental

contamination, and nutrient imbalances in plants. This study evaluates whether nutrient depletion can be achieved through water-based dilution as a practical approach for creating zero-nutrient soil suitable for controlled fertilizer experimentation. One cup of potting soil was mixed with increasing volumes of distilled water, alongside a distilled-water control. Nutrient concentrations of nitrogen (N), phosphorus (P), and potassium (K) were measured using Rapitest colorimetric analysis and digital coding devices. Soil slurries were tested before and after drying to determine whether nutrient depletion persisted beyond the aqueous phase. Results indicate that nutrient dilution is highly nutrient-specific. Approximately four gallons of water were required to lower N and P to “Deficient” levels, while K consistently remained “Adequate.” Upon drying the soil, previously diluted samples returned to “Adequate” nutrient levels for all components except nitrogen, which approached zero after extensive dilution. Phosphorus and potassium did not reach near-zero levels at any dilution, demonstrating resistance to depletion through water mixing alone. These findings suggest that while nitrogen can be substantially reduced through high-volume water mixing, water dilution is not sufficient for producing zero-nutrient soil for phosphorus or potassium. Future work will focus on controlled nitrogen fertilizer application and exploring more effective depletion techniques for P and K to support development of precise fertilizer-rate guidelines.

Abstract Name: Ghost Crabs Take the Spotlight: Ambient Artificial Light Pollutions’ effect on Atlantic Ghost Crabs (*Ocypode quadrata*)

Artificial Light pollution, the effects of artificial ambient light in natural spaces, is an emerging problem in rapidly urbanizing coastal ecosystems. Light pollution has well-documented impacts on the navigation, feeding behavior, and nesting activity of coastal organisms, like sea turtles and birds, however, has received less attention in non-vertebrates. For instance, Atlantic Ghost Crabs (*Ocypode quadrata*) are nocturnal mesopredators that visually seek prey items, evade predators, and are a common bioindicator species of human activity in beach ecosystems. Escape response behaviors are essential for ghost crab survival, and light pollution may impact their ability to visually detect predators and disrupt the production of Crustacean Hyperglycemic Hormone (CHH), a stress hormone synthesized in their eye stalks. To determine the impact of ambient light pollution on ghost crab escape response behavior, we collected and lab reared 15 crabs from a high-light urbanized beach and 15 crabs from a low-light undeveloped area of the beach on the West End of Dauphin Island, Alabama. We exposed crabs to a common light environment and measured escape responses following a stimulus of being pursued by a flashlight. Additionally, at experiment conclusion we collected hemolymph samples and eye stalks to measure CHH expression. Overall, we found that crabs from low-light beaches fought more, froze less, and burrowed less than crabs from high-light beaches. Additionally, we found males had more defensive behaviors (run, freezing) relative to females that were more likely to fight and burrow. Additionally, we found some evidence of plasticity in escape responses, crabs ran more and burrowed less when ambient night light was added in the lab. Our results provide one of the first assessments of escape response being sensitive to artificial light pollution and shows crabs from highly urbanized beaches may be less equipped to escape predators or children chasing them with flashlights.

Abstract Name: Seed Banking and Student Engagement Initiatives for the Conservation of Virginia's Native Plants

Seed banking is an important practice which maintains genetic diversity and provides “insurance” for plant species in case of disaster. Although this is most often done for crop species, the seed banking of native plant species cannot be overlooked as native plants are often the foundation of their respective ecosystem. Therefore the curation and amplification of Virginia’s native plant species is vital to the conservation and restoration of our local environment. The goal of this project was to contribute to building an ongoing, student-centered seed banking and plant restoration initiative. Additionally, this project aimed to lay a foundation for future student research opportunities and contribute to current ones. This was done by compiling information about the identification, storage, and germination of multiple species in the lab database into one comprehensible document. Seeds of multiple native species were also collected and curated, contributing to the actual supply of the seedbank. A Canvas course was built, including Seed Collection & Ethics and Plant Identification quizzes, which streamlines the participation of future VCU students. These efforts not only grew the seedbank, but also contributed to the successful amplification of multiple species (Blue mistflower, ironweed, joe pye weed, brown-eyed susan, and common evening primrose). Additionally, the collected seeds have provided support for ongoing research projects measuring rates of germination, response to hormones, growth rates, and microscopy.

Abstract Name: AI, Task Delegation, and the Future of Work in Emerging Markets: Evidence from the Turkish Retail Sector

This project will explore how retail firms in emerging markets are adapting to the rapid rise of artificial intelligence (AI), with a specific focus on task delegation. While AI is often discussed from a purely technical point of view, this research focuses on the human and organisational side, how people think, react, and make decisions when AI becomes part of their daily work. Using a Delphi-based approach supported by a Fuzzy Extended Analytic Hierarchy Process (FEAHP), we engaged senior leadership in the Turkish retail sector to identify six key dimensions that shape the adoption of AI: Adoption and Readiness, Human-AI Augmentation and Efficiency, Automation and Operational Shifts, Innovation and Strategic Value Creation, Ethical and Risk Management, and Organisational Learning and Coordination. AI, like other transformative technologies, introduces a democratizing force into workplace relations; studying this shift within an emerging market defined by high power-distance and hierarchical control, allows us to observe how ceding decision-making to AI reshapes task-worker outcomes [and the tensions that surface when authority becomes less concentrated at the top]. This ongoing research aims to forecast changes in task-worker outcomes which can help organisations in emerging markets implement the use of AI in ways that enhance human performance rather than widening gaps between technology and the workforce.

Abstract Name: Concern About Child Weight as a Predictor of Home Fruit and Vegetable Availability in a Healthy Lifestyle Intervention for Pediatric Cancer Survivors

Background: Caregivers play a central role in shaping children's nutrition through the foods they provide and encourage within the home. For pediatric cancer survivors, maintaining healthy dietary patterns is especially important due to elevated treatment-related metabolic risks and vulnerability to obesity. The aim of this study was to examine whether caregiver concern about child weight was associated with differences in the availability of fruits and vegetables in the home. **Methods:** The current study analyzed data collected from 253 caregivers of pediatric cancer survivors with overweight/obesity enrolled in a randomized control trial of a behavioral intervention focused on nutrition and physical activity. Caregivers reported their level of concern about their child's current weight on a 5-point scale and completed items assessing how often fresh or frozen fruits and vegetables were available in the home. A multivariate analysis of variance (MANOVA) was conducted to examine the effect of caregiver concern on child weight on reported fruit and vegetable availability. **Results:** Participants primarily identified as female (91%), White (69%), with an average age of 39.62 years (SD = 8.25). The overall MANOVA model was significant, $F(8,496) = 2.23$, $p = .024$, indicating that caregiver concern about child weight was associated with differences in home food availability. Follow-up analyses revealed significant effects for vegetable availability, $F(4,248) = 3.55$, $p = .008$, and fruit availability, $F(4,248) = 2.75$, $p = .029$. Caregivers expressing greater concern about their child's weight reported higher availability of fruits and vegetables within the home. **Conclusion:** Caregivers who are more concerned about their child's weight may increase the availability of healthier food in the household. This pattern suggests that caregivers may be motivated to encourage healthier eating by providing more fruits and vegetables at home. Future behavioral interventions may incorporate strategies to increase the availability of healthier options within the home.

Abstract Name: Characterization of a Fatty Acyl Elongase (gFAELO) in *Giardia lamblia*

Giardia lamblia is the causative agent of giardiasis; a globally prevalent intestinal disease transmitted through ingestion of contaminated food or water. The parasite alternates between two major life cycle stages: the trophozoite, an adherent and metabolically active form that proliferates in the host intestine, and the cyst, a dormant and environmentally resilient form responsible for ensuring transmission. The transition from trophozoite to cyst requires extensive cellular and metabolic reprogramming, including coordinated remodeling of membrane lipids and the biosynthesis of a robust cyst wall composed of proteins and carbohydrates. Although lipids are known to influence encystation, the specific contributions of many lipid-modifying enzymes remain poorly understood, limiting insight into how metabolic shifts regulate this developmental process. This study aims to characterize the role of the giardial fatty acyl elongase (gFAELO) in trophozoite-to-cyst differentiation, with a particular focus on how modulation of its activity—especially overexpression—affects cyst formation. The spatial and temporal behavior of gFAELO during encystation will also be assessed to better understand its potential regulatory function. To investigate gFAELO function, molecular approaches were used to modulate its expression, including the generation of gFAELO-overexpressing *Giardia* lines. A Halo-tagged gFAELO was also integrated into the genome to enable visualization of its localization during differentiation, providing a basis for future studies on its spatial and temporal dynamics. Overexpression of gFAELO resulted in a marked impairment of cyst formation, demonstrating that increased levels of long-chain fatty acid synthesis disrupt essential lipid-regulated steps of encystation. These findings suggest that precise control of gFAELO activity is necessary for successful differentiation. Understanding gFAELO's role in encystation provides valuable insight into the lipid-mediated regulation of *Giardia*'s life cycle and may aid in identifying metabolic vulnerabilities that could be targeted to reduce parasite persistence and transmission.

Abstract Name: Preoperative Anemia and Length of Admission in a Surgical Cohort: Simulation of Therapeutic Potential

Preoperative anemia, often prevalent in surgical patients, is associated with increased morbidity, costs, and prolonged hospitalization. This study utilizes a de-identified dataset of surgical admissions from the University of Copenhagen, Rigshospitalet, Copenhagen, Denmark, to retrospectively analyze the relationship between preoperative hemoglobin (Hgb) levels and length of admission (LoA), serving as a foundation for assessing the value of prophylactic iron transfusion as a preoperative anemia treatment. From surgical and blood-test datasets, we linked the lowest preoperative Hgb value per patient admission to LoA. LoA data were log-transformed to manage right-skew, and statistical outliers were removed using studentized residuals.

We used robust linear regression with heteroscedasticity-consistent standard errors to model the correlation between Hgb and Log-LoA across the full cohort of 41,003 patients and an anemic subset (Hgb < 8.0 mmol/L) of 22,279 patients. To estimate the potential benefit of iron transfusion, we conducted Monte Carlo simulations (n = 1,000) modeling Hgb increases while accounting for treatment non-responders and applying the model adjustments to patients' LoA to calculate "bed-days saved" (the aggregate of reduction in full admitted days per patient). The analysis confirmed a significant negative correlation between preoperative Hgb and LoA, with the anemic-specific model demonstrating an increased association. Applying the regression estimates to the anemic subset suggested that increasing Hgb by 0.5, 0.75, and 1.0 mmol/L could potentially save 6,755 (-3.12%), 9824 (-4.54%), and 13,037 (-6.03%) bed-days respectively, or per 1000 admissions 303, 440, and 585 bed-days respectively. These findings indicate that theoretical treatment of preoperative iron-deficient anemia could yield significant savings in hospital resource utilization. This analysis serves as the preliminary phase of a larger investigation, for which propensity score matching can be implemented to evaluate the causal efficacy of preoperative intravenous iron infusion in reducing LoA and blood transfusion risk

Abstract Name: Investigating the Effects of Exposure Time and Plasma Temperatures on Argon and Helium Plasma-Activated Water for Wound Healing

Dielectric Barrier Discharge (DBD) plasma is an emerging therapeutic option for wound healing. This is due to the generation of reactive oxygen and nitrogen species (RONS) through interactions between the plasma jet and liquid film of the wound surface. As the plasma jet dissociates and recombines surrounding air molecules, RONS are formed and solvated in the wound, bringing unique healing characteristics such as cell-signaling, immune defense, cell proliferation, and angiogenesis. This study investigated how variable plasma setup conditions like exposure time and plasma temperatures can manipulate the concentration of RONS (H₂O₂/NO₃/NO₂) and thus impact the therapeutic potential of DBD plasma for wound healing. RONS concentrations were quantified through absorption spectroscopy: Distilled water, modeling the wound surface, was exposed to a helium plasma jet for 5-15 minutes to create helium plasma-activated water (hPAW). Curve-fitting routines involved comparing hPAW samples within each time condition to calibration curves of varied concentrations of H₂O₂, NO₃, and NO₂ within its designated wavelength ranges through the Shimadzu 1900i spectrophotometer in order to quantify the RONS concentration in each hPAW time condition. However, samples within each condition exhibited a high coefficient of variance, ranging from 18%-62.28%, indicating that external factors besides plasma setup conditions like plasma temperature influence RONS concentration in hPAW. Additional current work includes the change of helium plasma with argon DBD plasma. Argon results are being compared to the helium case in terms of RONS concentration, though generated RONS are slightly different in this argon plasma case. This project will present calibration curves for RONS, helium-PAW, and argon-PAW. Curve-fitting routines and insights into factors impacting the DBD plasma will be presented. Its implications on the therapeutic treatments will be evaluated. The final presentation will include full experimental results for both argon and helium plasma.

Abstract Name: Addressing Heterogeneity in Meta-Analysis of Medical Data using MATLAB

This open-source MATLAB program provides student researchers with an accessible way to learn and apply meta-analysis techniques commonly used in the medical field. Meta-analysis is a trusted approach for combining results from multiple studies to evaluate overall effects and guide evidence-based decisions. Medical data are typically categorized as continuous, binary, or correlational, and the appropriate meta-analytic model depends on the dataset type. Accordingly, the program includes fixed-effects and random-effects models. For continuous data, the fixed-effect model uses mean, standard deviation, and sample size to calculate the bias-corrected standardized mean difference (Hedges' g). For binary outcomes, events and non-events across two groups are used to compute the Odds Ratio as the effect size. For correlational data, the correlation coefficient (r) serves as the effect size measure. Confidence intervals, z -values, p -values, and the variance of the true standardized mean difference are also computed. All MATLAB routines were validated using real medical datasets, including examples from Lin et al. (2013) on the impact of smoke-free legislation on acute myocardial infarction, and examples from Borenstein et al.'s Introduction to Meta-Analysis. A key component of the code addresses heterogeneity in effect sizes. Understanding heterogeneity requires separating true variation from random error, allowing researchers to evaluate dispersion in study outcomes. The MATLAB model calculates Q statistics (weighted squared deviations), corresponding p -values, between-studies variance (T^2), between-studies standard deviation (T), and the proportion of true heterogeneity relative to total observed variation (I^2). These statistics help determine whether variation across studies reflects meaningful differences or sampling noise. The open-source MATLAB package presented at this conference is freely available for use and adaptation. Each model includes validation results from multiple published studies, demonstrating the robustness of the algorithms and supporting their broader application in medical data analysis.

Abstract Name: Artificial Intelligence's Role in Clinical Decision-Making

Artificial intelligence (AI) systems are increasingly used to support diagnosis, risk prediction, and treatment planning, raising questions about how they influence physicians' clinical decision-making and ethical responsibilities. Studies suggest that while many doctors view AI as a promising decision-support tool, they also worry about transparency, bias, accountability for errors, and potential erosion of physician and patient autonomy. This literature review synthesizes current evidence on physicians' attitudes toward AI in clinical decision support, with a focus on how AI affects decision-making processes and key ethical principles. A narrative review was conducted by searching databases including PubMed and MEDLINE for peer-reviewed articles published between 2015 and 2025 that examined physicians' use or perceptions of AI-based tools in clinical care. Studies were included if they reported on decision-making, ethical concerns, or professional responsibilities related to AI, and were excluded if they focused solely on technical performance without clinician perspectives. The analysis also considered selected work on other health professionals to contextualize physicians' views within the broader healthcare team. Across studies, physicians generally endorsed AI as a way to enhance diagnostic accuracy and efficiency, especially for data-intensive or repetitive tasks, but emphasized that final clinical decisions should remain under human control. Common ethical concerns included algorithmic opacity, data bias and fairness, unclear legal liability, and risks to patient trust

if AI is used without adequate explanation or consent. Many authors argued that preserving physician decision-making autonomy requires sufficient information about AI tools, competencies to critically appraise AI outputs, and institutional policies that allow clinicians to deviate from AI recommendations when warranted. The review concludes that ethically robust integration of AI into medical decision-making will depend on targeted education for physicians, accountable AI design, and stronger guidance from professional bodies on responsibility, disclosure, and patient-centered use.

Abstract Name: Role of Ceramide Synthase 6-Generated Ceramide in Organelle-Specific Metabolism

Sphingolipids are essential lipids involved in membrane structure, signaling, and cell communication, with ceramides serving as central metabolites synthesized *de novo* in the ER by ceramide synthases (CerS1-6). Ceramide synthase 6 (CerS6) produces C16-ceramide, which can regulate apoptosis and tumor progression. Importantly, elevated CerS6 expression in high-grade cancers has been linked to poor prognosis. However, the precise role of CerS6-generated ceramide in organellar metabolism is not known. We aimed to investigate the role of CerS6-generated C16-ceramide in mitochondrial and lysosomal proteome and metabolism. We used parental (WT) and CerS6 knock-out (KO) HCT116 colon cancer cell lines which also express Mito-tag and Lyso-tag proteins with HA-tags to purify these organelles using rapid immunoprecipitation protocols. Following isolation, purity of the organellar fractions were validated using immunoblotting with several organelle antibodies. Targeted and untargeted proteomic and metabolomic analyses were carried out in the Massey Comprehensive Cancer Center shared resource facilities. Comparative analyses identified significant differences in organelle-specific metabolomes between WT and CerS6 KO cells. Targeted lipidomics data comparing the mitochondria from WT and KO cells showed notable alterations in mitochondrial sphingolipid composition. Ceramide levels were reduced in the CerS6 KO mitochondria compared to WT, accompanied by other significant changes in complex sphingolipids. These were downstream sphingolipid species, including hexosylceramides (HexCer) and sphingomyelins (SM), suggesting broader disruptions in mitochondrial lipid homeostasis. Moreover, in addition to significant changes in the sphingolipid content, untargeted metabolomics identified several pathways to be potentially regulated by ceramide in the lysosomes. These results suggest that CerS6 loss disrupts organellar sphingolipid metabolism and potentially affect organelle specific metabolic pathways and cellular signaling. Currently, we are defining the changes in the proteomes of these organelles that can mediate the changes in the metabolites.

Abstract Name: Nasal Carriage of Multidrug-Resistant *Staphylococcus aureus* Among University Students

Nasal carriage of *Staphylococcus aureus* (SA) is common in healthy individuals but remains a significant risk factor for future infection. This project examines SA carriage in college students—an understudied community population that experiences high interpersonal contact and widespread employment in frontline service jobs—and evaluates predictors of carriage. Nasal swabs and survey responses on demographics, workplace exposure, antibiotic use and knowledge, student-athlete status, and hygiene behaviors were collected from 81 consenting participants (IRB approval: 4419-081524-01). Swabs were stored at -80°C , enriched overnight in tryptic soy broth, plated onto mannitol salt agar, blood agar and CHROMagar *S. aureus*. Presumptive colonies were confirmed using catalase testing and latex agglutination. Confirmed SA isolates ($n=23/81$, 28%) were screened for antimicrobial resistance using CHROMagar MRSA and Kirby–Bauer disk diffusion for ciprofloxacin, tetracycline, cefoxitin, erythromycin, and clindamycin, including D-testing to detect inducible clindamycin resistance. Isolates positive on CHROMagar MRSA were additionally tested against rifampin and linezolid. Isolates exhibiting resistance to any antimicrobial ($n=8/23$, 35%) underwent broth microdilution to determine MICs for ciprofloxacin, erythromycin, and vancomycin. A total of 58 (71.6%) of isolates were coagulase negative staphylococcus species (CoNS), ~24.7% were SA and ~3.7% were MRSA. All MRSA isolates were resistant to at least one other antibiotic and three non-MRSA isolates had inducible clindamycin and erythromycin resistance. Preliminary analysis suggest that carriage in this cohort aligns more closely with community-acquired exposure than with healthcare-associated risk, with higher proportion of isolates recovered from students in food service and retail roles, while student athletes show no higher carriage than non-athletes. The inclusion of antibiotic knowledge as a behavioral predictor is another novel component that may clarify links between awareness, use, and resistance. Future analyses will incorporate 16S rRNA gene sequencing to increase detection sensitivity and expand characterization of the nasal microbiota.

Abstract Name: The Creation and Evaluation of an Ethnically Informed INQ-15 in BIPOC College Students

The Interpersonal Psychological Theory of Suicide (IPTS) proposes that the desire for suicide stems from perceived burdensomeness, thwarted belongingness, and acquired capability. This research study will focus on the two interpersonal aspects of the theory: perceived burdensomeness and thwarted belongingness. While the Interpersonal Needs Questionnaire (INQ-15) is widely used to assess these constructs, growing evidence suggests its items may not accurately capture the lived experiences of ethnically diverse individuals. This study addresses the limitations of the INQ-15 by creating and evaluating an ethnically informed version tailored to college students who identify as Black, Indigenous, or People of Color (BIPOC). We hypothesize that ethnicity-specific expressions of belongingness and burdensomeness will differ significantly from those captured by the standard INQ-15. Participants ($N = 165$) at a Midwestern public university will complete a self-report survey including the original INQ-15, our newly developed Ethnically Informed INQ-15, and the Multigroup Ethnic Identity Measure (MEIM-8). Using Qualtrics, SPSS, and a Multigroup Confirmatory Factor Analysis (MG-CFA), we will assess measurement invariance across versions of the scale. Preliminary findings from the literature suggest that factors like racial composition in social environments and systemic oppression can distort responses on standard IPTS measures. We hypothesize that the Ethnically Informed INQ-15 will demonstrate improved construct validity in the context of ethnic identity. Conclusions will inform the refinement of suicide risk assessments for BIPOC individuals and contribute to ethnically responsive mental health practices. Future directions include validating the revised scale in other minoritized populations and expanding its use in clinical settings to reduce cultural bias in psychological assessment tools.

Abstract Name: Spiritual Fatherhood in the Rule of St. Benedict

Benedict of Nursia renounced worldly goods and lived a life of Christian asceticism through prayer, work, and sacrifice. In the Rule of St. Benedict, instructions are given for those who wish to join this way of life in monasteries under the leadership of an abbot. For Benedict, the abbot holds “Christ’s place” (RB 2.2) and is the “father of the household” (RB 2.7) in the monastery. At the same time, monks are instructed in the Rule to “prefer nothing to... Christ” (RB 4.21). This presentation will show how, rather than detracting from the monks' obedience to Christ, the abbot governs in God’s name and acts as an instrumental cause of grace, through his office, to those in his care. Drawing on both medieval and contemporary scholarship on the Rule, I show that Benedict’s vision is that God shares his power of spiritual formation with the abbot. This understanding harmonizes God’s role as the ultimate object of obedience and source of all grace with the abbot's role as the immediate representative of the will of God to the monks. As the privileged mediator of Christ's will in the monastery, the abbot receives a temporal role of spiritual fatherhood from God, the eternal father of the monks, as he shepherds the souls of the monastic flock. I will draw on these insights from the Rule to demonstrate more broadly how God uses people as instrumental causes to dispense his grace and to nurture the faithful.

Discipline: Dance

Authors:

Abstract Name: Dance: Rehabilitative Resource to Lower Recidivism Rates

Dance is a rehabilitative method that can provide incarcerated individuals with the mental resources needed to be more equipped to reintegrate into society, which in turn will lower recidivism rates in the United States (U.S.). The U.S. has a high recidivism rate compared to other developed countries. This is due to a lack of providing incarcerated individuals with the mental and physical resources needed to successfully reintegrate into society once they are released. The U.S. focuses on a retribution approach to the prison system whereas most other developed countries focus on a rehabilitation approach. The prison system in the U.S. does not help mentally and emotionally prepare incarcerated populations for society like rehabilitation facilities do. Dance Movement Therapy (DMT) has been a therapeutic tool in the U.S. since the 1940s, but very little research has been done on its effectiveness on incarcerated populations. The mixed-method research methodology used combines numerical data on global recidivism rates and analyzes individual’s experiences with DMT to provide a complete overview of the results DMT can provide to incarcerated populations. Through DMT, incarcerated individuals can improve their social skills, personal identity, and mental health. These areas of growth can better prepare incarcerated populations to re-enter society. While research that directly connects dance to recidivism rates is still emerging, the evidence that suggests that DMT could lower recidivism rates is compelling. Dance may not be the sole solution, but it is an essential step towards utilizing rehabilitative methods that can be beneficial to incarcerated individuals and the U.S.’s prison system.

Abstract Name: You can't win, so win: How athletes and non-athletes respond to images of professional athletes

Previous research by Daniels and associates (2021) has found that athletes' presentation in the media impacts how the public views them. The current study examined how female, male, and gender expansive athletes and non-athletes responded to images of professional athletes. It was hypothesized that those who identified as athletes would experience more body dissatisfaction and disordered eating behaviors than those who did not identify as athletes, as well as athletes would experience more body dissatisfaction following viewing photos than non-athletes, and that women and gender expansive individuals would exhibit greater increases in body dissatisfaction than would men. A sample of 222 participants ($mAge = 33.38$, $SD = 11.70$) recruited from a mid-Atlantic University ($n = 39$) or Connect by CloudResearch ($n = 183$) completed the study via SurveyMonkey. Participants were exposed to four images of professional athletes of their identified gender, with 95 women (42.8%), 61 men (27.5%), and 66 gender expansive individuals (29.7%). 66.2% were Caucasian, and 91.9% were not of Latinx origin. Participants completed demographic information, the Body Appreciation Scale-2 (Tylka & Wood-Barcalow, 2015), and the Teruel Orthorexia Scale (Teruel et al., Barrada & Roncero, 2018). Before exposure began, after viewing each of the pictures of professional athletes, and at the end of the study, participants completed Visual Analogue Scales for weight, shape, and muscularity satisfaction (Slater et al., 2017). Athletes scored higher on body appreciation and a focus on healthy eating. However, athletes also showed higher levels of orthorexia nervosa, which should be closely monitored. Athletes were similarly less affected by viewing images of professional athletes. As hypothesized, women were more affected by viewing these images; however, surprisingly, they scored higher than gender expansive individuals and not men, indicating that images of athletes may affect those outside of the gender binary in ways yet to be explored.

Abstract Name: Compare and contrast of the design Aesthetics of African, African American, and Japanese designers: Historic to Modern day views

For this research, I will compare and contrast African, African American, and Japanese fashion designers and design aesthetics ; historic to modern day views. Exploring how culture and design aesthetics have evolved across time, utilizing visual and textual methods, I will engage with scholarly articles, past fashion shows, educational videos, and credible online sources to understand the intersections between heritage, innovation, and global influence. Historically, these cultures have drawn deeply from their traditions with African fashion from vibrant textiles and symbolism for storytelling, African American fashion from trendsetting, resilience and cultural expression, and Japanese fashion from precision, simplicity, and quality. Yet, each has also absorbed contrasting influences shaped by colonization, globalization, and modern identity. This study will undertake an in-depth examination of each culture and its representative designers, analyzing how shifts in

political, cultural, and technological contexts have specifically influenced the evolution of fashion within these societies. The knowledge gained will be applied to the creation of two garments titled “Shini” and “Venus.” Shini symbolizes moments of cultural fracture and destruction by reflecting pain, loss, and rebirth through the use of soft, deconstructed, and burnt fabric that still retain a sense of beauty. In contrast, Venus embodies love, unity, and hope, representing how each culture found strength and connection amid adversity. This garment will use structured, proportional forms and refined materials to showcase elegance and harmony. Together, these works will serve as a visual dialogue of contrast and connection, highlighting how fashion continues to be a reflection of identity, struggle, and cultural evolution.

Abstract Name: When Fish Flounder: Zebrafish (*Danio rerio*) as a Behavioral Model for Choice Paralysis under Reward Option Similarities

Choice paralysis is defined as a delay or failure to demonstrate a stable reward preference, arising from either choice overload (an excess of options) or the similarity effect (indiscriminable differences between two options). Although well characterized in humans and attributed to higher-order cognition, establishing an animal model could elucidate fundamental neurobehavioral mechanisms underlying this phenomenon. In the present study, adult zebrafish (*Danio rerio*) were used to quantify how reward similarity impacts choice latency in a discrete-choice instrumental T-maze task. Subjects chose between high- and low-fidelity social rewards presented across four similarity conditions (mirror images and same- or opposite-sex conspecifics) and a single dissimilarity condition (a food reward). Fish chose between two reward options across similarity conditions (mirror images and same- or opposite-sex conspecifics) or a single dissimilarity condition (a food reward), and preference stabilized when one option was selected in 8 of the last 10 trials after at least 15, or at 30 trials. Response latencies, blocked into deciles, were analyzed with mixed-factorial ANOVAs, revealing significant main effects of Block and Demonstrated Preference, plus Block $\times$ Sex and Block $\times$ Preference interactions, but no effects of similarity condition. Trials-to-criterion showed the same pattern: no sex or condition effects, but a robust influence of preference. Effect-size estimates for preference and trials-to-criterion fell in the medium-to-large range, supporting zebrafish choice paralysis as a tractable model of the neurobehavioral consequences of option similarity.

Abstract Name: Exact & Closed Form Solutions For The Kolmogorov-Petrovsky-Piskunov-Fisher Equation in Cartesian and Polar Coordinates

The Kolmogorov–Petrovsky–Piskunov–Fisher (KPP–Fisher) equation is a fundamental nonlinear reaction–diffusion partial differential equation (PDE) that plays a central role in population genetics, ecological

modeling, and combustion theory. It contains two distinct parts, which is a linear diffusion term and a nonlinear reaction term. The linear diffusion term governs the spatial spreading of the distribution through a classical second-order derivative. The nonlinear reaction term represents local growth or decay and depends solely on the value of the distribution itself, independent of any of its spatial derivatives. The standard analytical technique for solving the KPP-Fisher equation involves transforming the equation into a nonlinear ordinary differential equation (ODE) by a change of variables and analyzing the resulting wave form. The resulting ODE is then studied to determine admissible wave profiles and wave speeds that satisfy the required boundary conditions. While effective, this method relies heavily on classical similarity reductions and often requires nontrivial analysis to obtain explicit solutions. We will demonstrate that an alternative approach inspired by non-classical symmetries but only using elementary methods leads to exact and closed form solutions for certain choices of boundary conditions. We present examples involving quadratic and cubic source terms, also showing how the structure of the nonlinearity influences solvability. We also extend the analysis to both Cartesian and polar coordinate systems, demonstrating that the technique applies naturally to radially symmetric versions of the KPP–Fisher equation as well. This approach offers a easier to use and more accessible pathway for solving for exact solutions to a classical nonlinear PDE.

Abstract Name: Examining the Associations of Physical Activity and Genetics with Longevity: A Narrative Review of the Literature

Physical activity (PA) is widely associated with improved health outcomes and longer life expectancy, as numerous observational studies have reported robust inverse associations between PA and all-cause mortality. However, most of this evidence originates from general population-level observational research, where causal inference is inherently challenging. In particular, genetics may represent a critical source of residual confounding that complicates the efforts to separate the independent associations of PA from underlying biological predispositions. This criticism has been most prominently raised by Kujala and colleagues, who highlighted the limitations of standard confounder adjustment and introduced the concept of the healthy exerciser bias, which reflects that physically active individuals may live longer not because of their activity itself, but because they carry favorable longevity genes, such as predisposition towards better cardiovascular fitness (CRF). Additionally, findings from monozygotic twin studies, where genetic factors are inherently controlled, have reported minimal or no independent association with PA and mortality, further challenging conventional interpretations of observational data. Given these complexities, alternative research designs may provide stronger evidence regarding the causal role of PA in longevity, accounting for genetic confoundings. The purpose of this study is to conduct a narrative review of the literature, synthesizing the evidence, and examining whether the association between physical activity and all-cause mortality persists even after accounting for genetic predisposition. Particularly, we will focus on studies that employ the three most widely used methodologies for addressing genetic confounding: 1) Mendelian randomization (MR); 2) monozygotic twin studies; and 3) polygenic risk score (PRS)-involved observational studies. We will follow the process of systematic review to develop search strategies, establish inclusion/exclusion criteria, and organize the evidence for synthesis throughout an extensive literature review. We expect that the observed association between PA and mortality will vary across study designs depending on how genetic influences are addressed.

Abstract Name: Manipulation of RNA Polymerase III by Herpes Simplex Virus-1

RNA polymerase III (Pol III) transcribes noncoding RNA, including transfer RNA (tRNA), and is commonly targeted during cancer and viral infection. We applied a multi-omics approach to query the Pol III landscape in the context of Herpes Simplex Virus-1 (HSV-1) infection. HSV-1 infection upregulated Pol III type 2 genes, including 7SL, tRNA, and Alu elements. Notably, tRNA synthesis rates increased 10-fold. tRNAs are noncoding RNAs which decode mRNA codons to supply the appropriate amino acids during translation. tRNAs are essential for protein translation, a process taxed heavily during productive viral infection. The consequences of Pol III upregulation during HSV-1 infection are currently unknown. We hypothesize that HSV-1 upregulates the tRNA pool to promote viral translation. To test our hypothesis, we used RNA interference (RNAi) to deplete components of the Pol III transcription initiation complex (TBP, POLR3F, BDP1, BRF1). Orthogonally, we inhibited Pol III using the small molecule inhibitor, ML-60218. RNAi and inhibitor treatment had no significant impact on cell viability. Pol III inhibition was validated by RT-qPCR assessment of premature-tRNAs. Following RNAi in an infected keratinocyte model, we observed decreased viral progeny. In parallel, drug inhibition of infected fibroblast models (HdFn, MRC5) resulted in decreased viral genome replication, late genes, and progeny. Our findings support a model in which increased Pol III activity favors viral replication. These findings provide insight into mechanisms by which HSV-1 alters the Pol III landscape, shifting key ncRNAs to favor the pathogen.

Abstract Name: Federal Intervention and Local Crime: A Difference-in-Discontinuity Study of the 2025 Troop Deployments

Federal intervention in local policing intensified in 2025 when the Trump administration began deploying federal troops to Democratic-led cities. Prior federal mechanisms, such as pattern-and-practice investigations, have produced inconsistent effects on crime, raising questions about whether federal action meaningfully improves public safety. This study evaluates whether federal troop deployment reduces crime by analyzing Washington, D.C., the first city to receive troops, and Chicago, a comparable city publicly targeted but not yet deployed upon. Using daily crime incident data and a Difference-in-Discontinuity design, I estimate the causal impact of deployment by comparing changes in crime rates in D.C. before and after troop arrival with contemporaneous trends in Chicago. The results show extremely small estimated reductions in crime, typically less than one incident per day, and none are statistically significant. Additional analysis of violent crimes specifically, the policy's stated target, likewise reveals no measurable effect. These findings suggest that federal troop deployment is an ineffective and high-cost strategy for reducing crime. The results contribute to ongoing debates over federal involvement in local policing and the efficacy of aggressive public-safety interventions.

Abstract Name: Let's Get Blitzed? Performance Enhancing Drugs in National Socialism and their Pop Culture Afterlife

Why is pop culture so obsessed with Nazis on drugs? This research analyzes how, and why, contemporary pop culture and Nazisploitation films draw on the documented use of performance-enhancing drugs during the National Socialist era in Germany. Media tropes such as the Nazi mad scientist, zombie soldiers, and hyped super-soldiers borrow selectively from historical accounts of methamphetamine distribution within the Wehrmacht. Working within the conventions of Exploitation Cinema, Nazisploitation films use controversial and transgressive subjects such as military drug use to create spectacle in order to draw in viewers. These spectacles succeed because they simultaneously amplify Nazis into nearly invincible threats to democracy, and collapse them into ruined and addicted bodies. This contradiction produces a satisfying narrative cycle for audiences who get to repeatedly defeat an enemy portrayed as both unnaturally powerful and profoundly debased. These depictions are not historically accurate. Instead they offer audiences a way to relive the story of the victor. Viewers return to these films because of the reward of defeating a villain engineered to be undefeatable, but only because of their unfair reliance on performance-enhancing drugs, a signal of their moral inferiority. Thus, the genre reinforces an American postwar identity built on triumph and a clear moral line between “us” and “the epitome of evil.”

Abstract Name: The State Beneath the Skin: Tattoos as Uncensored Testimony in Russian Prisons

What explains the emergence of Russian prison tattoos as a discourse of resistance in post-Soviet Russia? Once targeted for erasure by the Soviet Union, these symbols have gained prominence since its collapse, evolving from stigmatized criminal markers into a complex communicative system that shapes identity, authority, and belonging both within and beyond penal institutions. Rooted in codified prison hierarchies, these tattoos originally served as visual records; over time, they became a legible language conveying moral codes, survival strategies, and subtle forms of resistance in environments of strict oversight. While research on Soviet-era tattoos emphasizes codified systems of carceral resistance, studies of contemporary authoritarianism highlight increasingly individualized, aestheticized dissent. These literatures imply different expectations about how symbolic resistance operates today. This study analyzes prison tattoos as a form of carceral communication: encoding identity, norms, and resistance for incarcerated individuals, while transmitting collective memory, counter-narratives, and moral codes to the broader public. Employing a comparative multimodal discourse analysis, a corpus of 84 post-1991 tattoo images was examined alongside testimonial and institutional texts. Tattoos were systematically coded by motif (e.g., stars on the shoulders, barbed wire on the forehead, American iconography), anatomical placement, inferred meaning, and official classification. The images were then interpreted through critical, subcultural, and identity theory to trace how visual symbols articulate both legitimacy and dissent. The findings reveal a paradox: within a society marked by increasing surveillance and declining trust, the semiotic order of the criminal subculture has become a more stable and intelligible medium of communication than the language of the state. Russian prison tattoos operate as enduring systems of moral and political knowledge, offering a critical case for understanding how

subcultural discourses acquire cultural authority when official narratives lose credibility in transitional authoritarian states.

Abstract Name: Tracing Genetic Continuity Between Ancient and Present-day Humans in Southern East Asia Using a Diffusion-Based Model

Understanding whether present-day populations descend directly from ancient groups remains a central challenge in human population genetics, especially in regions with complex population histories. Southern East Asia (SEA), in particular, presents a complex demographic landscape shaped by migration, admixture, and genetic turnover. Yet despite the substantial growth in ancient DNA (aDNA) sampled from East and Southeast Asia in the last 5 years, the population histories of these regions are still not well-characterized, and researchers still lack streamlined tools to determine whether specific ancient groups contributed ancestry to present-day SEA populations. Our project addresses this challenge by developing a computational pipeline that assesses the genetic continuity between ancient and modern human groups. It applies a previously published test of direct ancestry that uses a diffusion-based statistical tool that evaluates whether allele frequency patterns in present-day populations are consistent with direct genetic descent from ancient groups. By implementing automated file processing, robust quality control, flexible sample groupings, and customizable inclusion/exclusion criteria, this pipeline allows us to run continuity tests reproducibly on thousands of ancient individuals. After validating the pipeline using well-studied European ancient genomes we applied it to aDNA uncovered from SEA, including recently published genomes from Yunnan and earlier datasets from surrounding regions. Preliminary results reveal which ancient populations may have contributed ancestry to present-day SEA groups and provide new insight into long-term population stability, regional migration patterns, and shifts in population structure.

Abstract Name: Synthesis of High-Entropy MXene via Lewis Acidic Molten Salt Etching

Since the discovery of graphene in 2004, two-dimensional (2D) materials - ultrathin sheets just a few atoms thick - have attracted enormous scientific interest for their unique properties. Among them, a family known as MXenes, discovered in 2011, stands out for its compositional tunability, exceptional electrical conductivity, and tunable surfaces. These qualities have made MXenes promising candidates for next-generation applications in energy storage, water purification, and biosensing technologies. Recent developments have focused on synthesizing high-entropy MXenes, derived from high-entropy MAX phases containing four or more transition metal species in the M-layer. Traditionally, these materials are prepared via selective etching

of the A-layer using hydrofluoric acid (HF), a hazardous and environmentally unfriendly reagent known for its extreme toxicity and corrosivity. This project aims to circumvent the use of HF by employing Lewis acidic molten salts (LAMS) as an alternative etchant. The approach utilizes the reactivity and thermal stability of molten halides to selectively remove the A-site element (typically Al) while preserving the multi-metal M-layer. By optimizing key reaction parameters - temperature, reaction time, and salt-to-MAX ratio - we demonstrate the feasibility of this etching strategy for producing high-entropy MXenes under safer and potentially scalable conditions. These findings lay the groundwork for future studies aimed at expanding the synthetic means for MXene production and tailoring their surface chemistry for catalytic applications.

Abstract Name: Deciphering Postsynaptic Architecture by Structural Characterization of the Gephyrin Ortholog Cinnamon

Glycine (Gly) and γ -aminobutyric acid (GABA) are predominant inhibitory neurotransmitters in the mammalian brain, recognized by GABA type-A (GABAA) and Gly receptors (GABAARs and GlyRs, respectively). A significant portion of GABAARs and GlyRs are recruited and anchored to the postsynaptic membrane by the central scaffolding protein gephyrin, with other moonlighting functions, such as serving an essential role in molybdenum cofactor (MoCo) biosynthesis. Gephyrin is structurally organized into an N-terminal G-domain (GephG) connected to a C-terminal E-domain (GephE) via a large highly unstructured linker C domain. At postsynaptic sites, gephyrin has been proposed to form a hexagonal lattice through G-domain trimers and E-domain dimers. As a highly conserved protein, several gephyrin orthologs have been identified across species. In mammals, the homologs are involved in both moonlighting functions, while other organisms, such as prokaryotes and plants, are limited to MoCo biosynthesis. Previous studies demonstrated that the gephyrin ortholog in *Drosophila melanogaster*, cinnamon, exhibits identical functions as that of gephyrin. While structural studies have been conducted with isolated GephG and GephE, full-length gephyrin has been difficult to study presumably due to the highly unstructured and proteolytically-sensitive linker C region. Among the known gephyrin homologs, cinnamon features a significantly shorter linker that makes it an attractive candidate to explore inhibitory postsynaptic architecture. We therefore recombinantly purified the full-length cinnamon and subsequently conducted structural studies employing Cryo-electron microscopy (Cryo-EM). Our preliminary studies demonstrate a concentration dependent conformational heterogeneity in cinnamon, with the majority of molecules exhibiting a potential trimeric state.

Abstract Name: Integrative Transcriptomic and Radiomic Profiling of Pancreatic Cancer

With 97% of patients diagnosed with pancreatic cancer, only 3% survive for longer than 5 years post-diagnosis, presenting a global healthcare crisis. To help identify biomarkers and improve early-stage detection, this project integrates transcriptomic and radiomic data to characterize tumor heterogeneity and discover molecular signatures associated with patient outcomes. We analyzed a rare multi-omics dataset from 15 patients in the University of Nebraska Medical Center's Pancreatic Rapid Autopsy Program (RAPID), which includes gene expression data and CT scans for both primary and metastatic tumors. This dataset provides an opportunity to study molecular and imaging features across spatially distinct tumor sites. To identify potential biomarkers, we first used a large public dataset (TCGA) of primary pancreatic tumors to find groups of tumors with similar gene-expression profiles. We trained a machine-learning model to recognize these groups and then applied it to the primary tumors in the RAPID cohort to test whether the same biological patterns appear in an independent dataset. In the TCGA cohort, additional clustering of gene-expression data revealed three tumor subtypes. We identified some survival-linked molecular markers whose expression patterns distinguish patients with different clinical outcomes, such as SLC2A1. When applied to the RAPID cohort, the predicted subtypes showed a trend toward differing survival times. To expand multi-omics integration, the next step of the study links radiomics features from CT scans with the transcriptomic data to identify cross-modal signatures of tumor heterogeneity. Together, this project establishes a multi-omics framework for biomarker discovery and provides insights into tumor progression that may support more individualized treatment strategies for pancreatic cancer. These findings will be discussed in the context of improving early detection and defining biologically meaningful patient subgroups.

Abstract Name: Characterizing mCAs by Age, Sex, Ancestry, and Genomic Location to Predict Hematologic Malignancy in the All of Us Research Program

Hematopoietic stem cells are precursors for all blood cell types, which, during the maturation process, may accumulate genomic mutations. While many of these mutations have minimal impact, some confer a competitive advantage, leading to the formation of large colonies of clones—a phenomenon known as clonal hematopoiesis. This process has been linked to several diseases, including heart disease, arteriosclerosis, and hematologic malignancies. Notably, by the age of seventy, approximately 10% of the healthy U.S. population exhibits clonal hematopoiesis, with prevalence increasing exponentially with age. One significant mutation type contributing to clonal hematopoiesis are mosaic chromosomal alterations (mCAs), whereby substantial portions of somatic DNA undergo alterations. Importantly, certain mCAs have an increased association with the development of hematologic malignancies, and their prevalence varies across demographic groups. To explore these relationships, we utilized the All of Us Research Program, which offers comprehensive health records from a diverse set of individuals which previous studies have often lacked. We found that frequencies and chromosomal locations of autosomal mCAs differ based on age, sex, and ancestry, with implications for predicting both hematologic malignancy and other diseases. This was concluded following mCA frequency analysis across individuals of varying demographics, identification of chromosomal aberration loci hubs within these groups, and finally, assessment of whether the identified mCAs predict the onset of blood cancers. Recent findings across four large-scale biobanks include identification of novel risk loci that modulate mCA risk and associations with other diseases with emphasis on blood cell count abnormalities. Future analysis involves finding and characterizing associations between blood pressure irregularities and mCAs across various biobanks. By uncovering demographic-specific patterns of mCAs, we aim to tailor personalized cancer prevention and treatment strategies, recognizing the diverse genetic variability underlying hematologic malignancies.

Abstract Name: Microbial Resistance in Livestock Communities

Livestock are given preventative medications to aid in keeping them healthy, and the excretion of this medication through waste is a large contributor to the spread of antibiotic resistance in the environment. Farmville, Virginia has a large farming community, so it is expected to have more antibiotic resistant bacteria, especially near livestock locations. Through this project, a methodology was developed to collect air samples using a 3D printed device and fan. Three air samples were collected both from a horse pasture and Longwood University's campus. These air microbes were caught on HVAC filters, were grown on LB plates for one week, and then the DNA was extracted. The DNA was quantified using nanodrop and qubit. Samples were barcoded using the 16S library kit from Nanopore, sequenced using a Nanopore Flongle device, and analyzed using EPI2ME software to determine the genera present in each sample. The air microbiome between the horse pasture and Longwood's campus were different from one another, with some genera unique to each location. Antibiotic specific primers will be utilized to determine the presence of antibiotic resistance. Aminoglycosides, macrolides, tetracyclines, quinolones, fosfomycin, trimethoprim, and beta lactam resistance genes were selected for their significance in livestock and human health. Primers were designed to target the ermB gene, which causes erythromycin resistance in bacteria. The primers were verified using PCR, and through qPCR a standard curve was developed and presence of the gene was quantified in each sample. Higher presence of the ermB gene was found in the horse location, meaning there was more erythromycin resistant bacteria in that community. Future directions include qPCR with remaining primers and sampling cow, chicken, and pig locations. This research is important in establishing a baseline of antibiotic resistance in the Farmville community to better aid in animal and human healthcare.

Abstract Name: The Effect of Short-Chain Fatty Acids on Neurogenesis: Uncovering a Mechanistic Link in the Gut-Brain Axis

The gut-brain axis is a bidirectional communication system between the central nervous system and the digestive tract, involving the brain, gut, and the gut microbiota. The gut-brain axis is important because it is the means of communication between the gut and brain, and it influences mood, cognitive ability, and overall health. The study of the gut-brain axis is important because it can develop new treatments for things like anxiety, depression, and irritable bowel syndrome, which are debilitating diseases that are seen frequently in the world today. Short-chain fatty acids (SCFAs) are produced by the microbiota of the gut and occur naturally from the fermentation of dietary fiber. SCFAs have far-reaching effects, influencing the immune system, metabolism, and even brain function by affecting cells in various parts of the body. SCFAs are thought to play a large role in the communication of the gut-brain axis. Neurogenesis is the process of generating new neurons and is responsible for creating the brain's network of neurons. Human mesenchymal stem cells (hMSCs) were grown and differentiated using differentiation media, and fluorescent microscopy was used to confirm the identity of the neurons and several of their structures, like the nucleus. The goal of

this project is to differentiate hMSCs into neurons in the presence of different concentrations of SCFAs to observe how differentiation is altered. Gene expression of the neurons would then be observed to see how SCFAs impact neurogenesis. This will make clearer the form of communication that is used by the gut-brain axis.

Abstract Name: Investigating Impact of Estrous Cycle, Gonadectomy, and Selective G-Protein Estrogen Receptor Agonism on Inflammatory Pain Using Formalin Testing Model

Inflammatory pain is a key component of acute traumatic pain and chronic rheumatic disease, which significantly reduces the quality of life of those who suffer from it and is often resistant to available treatments. Despite changing policies, there are still a disproportionately high number of pain studies conducted on males compared to females, despite the majority of pain patients being women. Baseline sex differences in inflammatory pain must first be understood in order to guide the development of more effective treatments. Therefore, this study evaluated baseline sex differences in C57BL/6J male and female mice using a formalin model of inflammatory pain. Upon observation of significant sex differences, further investigation was conducted by assessing female mice at each phase of the estrous cycle and through examining the effects of gonadectomy (ovariectomy or castration). Female mice in the metestrus or diestrus phase had decreased inflammatory pain relative to both male mice and female mice in the proestrus or estrus phase. Ovariectomy resulted in decreased pain, which was restored through treatment with estradiol (E2). Castration similarly reduced pain in male mice. Injection of the G-protein coupled estrogen receptor (GPER) agonist G1 resulted in significant antinociception in both female and male mice, regardless of whether they had received sham surgery or gonadectomy. These results establish baseline sex differences in the formalin model of inflammatory pain and support the need for further investigation into the relationships between sex hormones and the regulation of nociception.

Abstract Name: Therapy in the Age of AI: How Young Adults Seek Help, Support, and Solutions

Therapy has long been a foundational approach for addressing mental health, but advances in digital technology have led many young adults, especially Generation Z, to increasingly turn to AI tools for support. Rising costs, limited access to providers, and long wait times have further boosted the appeal of AI-based mental-health solutions. Despite this growing interest, the use of AI for emotional and psychological support raises important questions about trust, empathy, safety, and the ethical responsibilities of mental-health providers and developers. We conducted a brief scoping review of research on AI-based mental-health tools

and student help-seeking behaviors. Searches were performed on Google Scholar and publicly accessible academic sources from 2020 to 2025 using keywords related to “AI mental health,” “chatbot therapy,” “student help-seeking,” “Gen Z mental health attitudes,” and “digital counseling tools.” Eight articles met inclusion criteria. A standardized five-sentence template was used to summarize each study, covering the citation, purpose, participants, key findings, and relevance to AI and help-seeking, and themes were identified through qualitative synthesis. The findings highlight four key themes: (1) students value the accessibility and professionalism of AI but ultimately trust human therapists for deeper emotional issues; (2) AI chatbots often lack empathy and may give inappropriate or emotionally unsafe responses; (3) young adults are willing to seek help but prefer human connection for emotional support; and (4) AI could be a helpful addition if improved for emotional safety and regulation. Although AI has the potential to improve accessibility and reduce wait times, students do not view it as a replacement for human therapists, especially when addressing deeper emotional needs. Further research is needed to examine ethical safeguards and the long-term effects of AI-supported mental-health services for Generation Z.

Abstract Name: Promoting Healthy Living: A Targeted Intervention for Teen Parents

Purpose: For this project, we implemented a health intervention targeting teen parents, focused on reducing stress and practicing healthy habits. We partnered with a teenage parenting program at an alternative high school in Northern Arizona. We designed, implemented, and evaluated three evidence-based health activities for seven current or expecting teen moms. This intervention aimed to increase teen moms' knowledge and self-efficacy in managing their stress levels through adjusting physical activity, nutrition, and mindfulness. **Research Context:** Teen parents are more likely to experience poor mental health outcomes compared to other parents or teens. Teen parents deal with stress from school, parenting, and finances. Poor mental health outcomes can negatively affect a teen parent's success in school, bonding with the baby, and personal health. **Intervention methodology:** Social Cognitive Theory (SCT) guided our intervention. SCT helps explain why people adopt certain behaviors by showing how personal, behavioral, and environmental factors interact to influence behavior. For our first activity, students participated in a walk using baby carriers and engaged in conversations about the importance of physical activity and mental health. For our second activity, we facilitated a meal preparation lesson with students and prepared two meals together. Meal prepping helps people plan healthy meals and removes the stress of preparing meals throughout the week. In our last activity, we taught and practiced mindfulness yoga. **Conclusion:** To evaluate the effectiveness of our intervention, students took a pre- and post-test for each activity. We evaluated the students' self-efficacy in performing the activities on their own time and their stress levels before and after each activity. We found that overall, the students demonstrated an increase in self-efficacy and lower stress, indicating that engaging in health activities can support the well-being of teen parents. This intervention can be used in other alternative high school settings for teen parents.

Abstract Name: Utilizing Exercise to Prime the Anxiolytic Effects of High-Definition Transcranial Direct Current Stimulation

Anxiety disorders are the most common mental health condition in the United States, affecting 40 million individuals, roughly 19.1% of the population. Although anxiolytic medications such as SSRIs and benzodiazepines are widely used, their side effects are substantial. Thus, the challenge of addressing the high prevalence of anxiety has not been adequately met, and interest has grown in non-invasive, safer alternatives. High-definition transcranial direct stimulation (HD-tDCS) is a viable option for precise stimulation of specific regions of the brain, including the dorsolateral prefrontal cortex (DLPFC), a region known to be hypoactive in individuals with anxiety. Interestingly, moderate physical activity has been shown to produce acute anxiolytic effects by improving brain oxygenation and promoting parasympathetic activity. However, no studies have examined whether exercise can help as a physiological primer to increase the effects of HD-tDCS. It is accepted that tDCS increases the neuronal resting membrane potential, promotes synaptic plasticity, and enhances neural network functional connectivity. However, studies utilizing HD-tDCS have revealed inconsistent results, likely due to varying protocols and subject heterogeneity. Thus, the effects of exercise may serve to prime the neuronal pathways and enhance the effectiveness of HD-tDCS. To investigate the possible priming effects of exercise, each participant will complete three experimental sessions: moderate-intensity exercise followed by HD-tDCS; exercise followed by sham; and HD-tDCS alone, therefore serving as their own control. The exercise intensity will be set at 65% of each participant's heart rate reserve (determined via submaximal test), a level consistently shown to reduce anxiety in prior research. To explore the plausible underlying mechanism, near-infrared spectroscopy (NIRS) will assess oxygenation changes in the prefrontal cortex, and heart rate variability (HRV) will serve as a proxy of parasympathetic activity. We hypothesize that combining HD-tDCS with physical activity will yield a superior anxiolytic response compared to either intervention alone.

Abstract Name: Constructing Texas Identity Through Modern Entertainment in 1936: A Comparative Analysis of the Dallas Fair Park and Casa Manana

This research is a comparative study and analysis of The Texas Centennial of 1936, where organizers and key leaders in Dallas and Fort Worth used rival entertainment complexes to define "Texas" for visitors and residents. This project compares the official Texas Centennial Exposition at Dallas Fair Park with Fort Worth's privately run Frontier Centennial and Casa Manana cafe theater. Using The Centennial newsletters, postcards, photographs, local newspaper coverage, and later scholarship, the project traces how architecture, lighting, performances, and advertising built competing stories about Texas identity. At Fair Park, New Deal style buildings, the Hall of State, patriotic parades, rodeos, Shakespeare plays, and the Bluebonnet Girl hostess presented Texas as a unified commonwealth with a heroic past, modern industry, and respectable family culture. In Fort Worth, Billy Rose's revolving stage, water ballets, showgirls, imported Broadway acts, and the slogan "Forty-five minutes west to Whoopee" promoted an entertainment frontier centered on glamour, mechanical spectacle, and cowboy myth. The study also follows these sites beyond 1936, noting

how permanent buildings at Fair Park and the reborn Casa Manana theater continued to stage musical productions for North Texas audiences, so generations learned regional pride through leisure. Additionally, I have conducted close reading of visitor quotations, postcards, and staging details highlights emotional responses such as pride, wonder, and amusement among fair visitors. Further, by reading these popular entertainment sites as historical sources, the project shows how fairs, theaters, and mass amusements shaped ideas about belonging, gender, and modernity, and invites audiences to think about how present-day entertainment venues still teach shared identities and regional stories across social class and regional lines.

Abstract Name: Compassion or Exploitation? The Complexity of the Medical Gaze in The Elephant Man

"I am not an animal! I am a human being!" cries John Merrick in David Lynch's 1980 film *The Elephant Man*. This powerful statement has become a symbol of human dignity against cruelty, but beneath its compassion lies a more unsettling truth that even the most empathetic portrayals of Merrick remain structured by the same gaze that first dehumanized him. Based on a real man exhibited in Victorian freak shows and later "rescued" by Dr. Frederick Treves, Merrick's story is often told as one of kindness and friendship. However, each retelling, the memoir by Treves, the play by Bernard Pomerance, and Lynch's film, reproduces the Western gaze's project that defines humanity through spectacle, difference, and control. This project interrogates how language and representation across these three works perpetuate the medical gaze. The gaze, initially born within medicine, expands into cultural and artistic forms, transforming the concept into something both empathic and exploitative. Drawing on Michel Foucault's theory of the clinical gaze, Rosemarie Garland Thomson's account of freakery as a cultural construct, and Linda Tuhiwai Smith's work on the "cultural archive," the paper examines how Merrick is viewed as spectacle due to the construction of difference and how Western knowledge systems reduce the "Other" to an object of observation. By tracing how *The Elephant Man* has been rewritten from the clinical memoir to the stage play to the film, I argue that the narratives' supposed compassion masks a deeper continuity of power and manipulation. Although these works are typically viewed as narratives of compassion, they collectively serve the same function of exploitation from a neo-colonial perspective, situating Merrick as both spectacle and specimen and uncovering the broader project of the West.

Abstract Name: Rebuilding Merit: A Constitutional and Operational Framework for Race-Neutral Admissions at the United States Service Academies

This research study explores a new methodology for how service academies in the United States should structure admissions after Students for Fair Admissions (SFFA) and the 2025 Department of War mandate establishing a merit-only selection process. This study combines constitutional doctrine with empirical measures of officership, presenting an original, post-SFFA model designed to the academies' specific missions, structures, and legal postures. Even assuming national security and unit cohesion constitute compelling interests, race-conscious admissions are both constitutionally vulnerable and operationally

unwarranted, while race-neutral, character-based merit presents a more defensible alternative. Regarding the methodology, this study combines doctrinal analysis of equal protection, case law, explanation of recent litigation against USMA and USNA, and engagement with empirical work. Specifically, the works from RAND, the Government Accountability Office, and Department of War demographic reports were used to examine whether military-specific interests can satisfy strict scrutiny and what narrow tailoring requirements would follow. Furthermore, this study examines race-neutral resources, congressional-district outreach, expanded preparatory and bridge programs, and candidate scoring that weighs academics, fitness, leadership, and demonstrated resilience. While some of these factors are already available at the academies, these methodologies may be able to sustain a credible officer pipeline without racial classifications. The project also incorporates a discussion of the researcher's personal path through the Air Force Academy's Falcon Foundation preparatory program to explore how neutral pipelines can help candidates overlooked by test-centric definitions of merit. It concludes that current Supreme Court doctrine leaves minimal room for race-conscious policies and strongly supports a transparent merit framework through previously established predictors of officership, neutral pipelines, and recurring audits. This project places this methodology within broader debates over affirmative action, military relations, and constitutional deference to the armed forces, arguing that equal protection and mission effectiveness are mutual obligations for the service academies.

Abstract Name: Evaluating the Impact of Soft Drinks on Bacterial Growth and Biofilm Development

Soft drinks are consumed globally in both regular and diet forms, and many are marketed with added vitamins or plant extracts. While their metabolic and health impacts are well studied, little is known about their antimicrobial properties and potential influence on microbial growth. This study investigates the antimicrobial activity of Monster, Red Bull, and Ginger Ale, along with their diet counterparts and vitamins B2 and B3, at varying concentrations. A broth assay using 96-well plates was performed against 20 microorganisms, including both Gram-negative and Gram-positive bacteria and fungi. Growth inhibition and biofilm formation were assessed. Monster and Diet Monster showed strong inhibitory effects against several bacterial strains, including *Pseudomonas aeruginosa*, *Bacillus cereus*, *Escherichia coli*, and *Staphylococcus aureus*. Ginger Ale and Diet Ginger Ale produced variable results, sometimes increasing and other times reducing microbial growth. Red Bull and Diet Red Bull displayed moderate inhibition, primarily against Gram-positive species such as *Staphylococcus epidermidis*, *Streptococcus oralis*, and *S. aureus*. At higher concentrations, several beverages promoted biofilm formation. Vitamins B2 and B3 showed no significant activity, except for slight inhibition with vitamin B3 against *P. aeruginosa*. These findings indicate that certain energy drinks, particularly Monster and Diet Monster, contain compounds with notable antimicrobial properties. The observed biofilm formation at higher concentrations raises concerns about unexpected microbial responses. Future work will focus on isolating and characterizing the active compounds responsible for these effects to better understand their biological significance.

Abstract Name: Identification of Novel mRNA Targets of miR-379-5p in Breast Epithelial Cells

microRNA-379-5p (miR-379-5p) is downregulated in breast cancer and may exert its effects through the suppression of key mRNA targets. Building on prior bioinformatic work that identified several negatively correlated and tumor-upregulated candidate genes using miRDB, TargetScan, and Firebrowse, this study aimed to experimentally determine which mRNAs are directly downregulated by miR-379-5p in normal mammary epithelial cells (AG11132). Using established transfection protocols, cells were treated with a miR-379-5p mimic or negative control, followed by RNA extraction and qRT-PCR analysis of ten prioritized genes. Across multiple replicates, HLCS and SLC20A1 consistently exhibited higher Cq values and reduced expression in mimic-treated cells, indicating that they may be direct targets of miR-379-5p. These findings highlight promising regulatory mRNA candidates in breast tissue whose elevated expression and strong negative correlation with miR-379-5p suggest biologically relevant roles in breast cancer and warrant further investigation.

Abstract Name: Navigating the Accommodation Process for Reproductive Events in Higher Education Settings: Multi-stakeholder Perspectives

Research Questions: 1) “How do accommodations facilitators and seekers describe the pathways to seek and receive accommodations for a pregnancy or parenting event?” 2) “What are the barriers and facilitators in this process?” Background: Within the university setting, student parents face many barriers to occupational and academic success including inflexible attendance policies, unempathetic professors and lack of institutional knowledge on how to seek support effectively. While accommodations can help address some of these barriers, individuals experiencing a reproductive event in university settings report not seeking accommodations due to factors such as negative and stigmatizing interactions with faculty and staff, time poverty, and perceived or actual lack of university support. The decision-making perspectives of people seeking formal accommodations is not well discussed in present scholarship and there is a dearth of information on the perspective of accommodations facilitators. Methods: Through semi-structured individual in-depth interviews with accommodations seekers and facilitators, this study highlights the lived experiences of students who sought an accommodation for a reproductive or parenting events in the university setting and explores the perspectives of those facilitating accommodations. Participants were recruited from a convenience sample utilizing snowball sampling and social media outreach through large 4-year universities in the southeast. Data were analyzed through a mixed inductive-deductive integrated reflexive thematic analysis, utilizing the socioecological model explicate the multi-level determinants impacting decision-making. Results: Preliminary results reveal barriers in the accommodations process including gaps in facilitators’ understanding of their roles and responsibilities as they pertain to accommodations required by Title IX, inadequate education for accommodations seekers, and stigma surrounding Title IX and student pregnancy. Implications: Findings highlight opportunities for universities to better support students experiencing reproductive and parenting events through the accommodations process and gaps to address in the accommodations pathways.

Abstract Name: Chemical Pressure Effect in the Magnetocaloric Candidate CrNiP

The magnetocaloric effect, a thermodynamic phenomenon, can provide a more efficient and environmentally friendly route for cooling technology compared to traditional compressor-based systems. The rare-earth free MM'X alloys where M and M' = transition metal and X = main group element, have received much attention as promising magnetocaloric candidates. These materials have shown to exhibit a strong magnetostructural coupling resulting in a large entropy change typically over a wide temperature region, optimal for magnetic refrigeration technology. In this talk I will present the results of the chemical pressure effects on the MM'X alloy magnetocaloric candidate, CrNiP. With Sb or S substitution on the P atomic site in CrNiP, a spectrum of positive and negative chemical pressure is created where the material undergoes a structural transition from the hexagonal Ni₂In-type to the orthorhombic TiNiSi-type and finally to the hexagonal FeP₂-type structure. Subsequently, this significantly alters the magnetic behavior, resulting in either or coexisting antiferromagnetic and ferromagnetic order. Our results reveal chemical pressure as an advantageous tool to tune the structural and magnetic behavior in the MM'X alloy CrNiP and ultimately provide a source of control over the magnetocaloric properties.

Abstract Name: Evaluating Decellularized Human Muscle Matrix as a Translational Scaffold for Volumetric Muscle Loss Repair

Volumetric muscle loss occurs following high-velocity trauma such as gunshot wounds, blast injuries, or car accidents. These types of injuries result in the loss of a large volume of muscle, reducing motor function and limiting mobility. To address these injuries, one approach involves preparing a biologic scaffold by isolating the decellularized muscle matrix (DMM), which contains regenerative factors that stimulate de novo muscle growth. While our group has demonstrated success in preclinical models, our goal is to begin testing these grafts in clinical trials. As a first step in this process, we need to evaluate the effectiveness of the decellularization process in human muscle. We quantified remaining cellular and extracellular matrix components within aged human latissimus dorsi. DNA quantification assays were performed to measure remaining nuclear material by comparing tissue samples before and after decellularization, confirming that DNA levels were reduced to nearly undetectable levels. Protein quantification assays were performed to evaluate the overall protein content remaining after decellularization, helping confirm that key extracellular matrix proteins were preserved while cellular proteins were removed. Ongoing work will characterize the extracellular matrix proteins within the decellularized matrix using proteomics to evaluate the potential for these grafts to elicit regeneration. These results highlight the translational aspects of these skeletal muscle grafts and demonstrate their potential to be used in volumetric muscle loss repair.

Abstract Name: Investigating the Postmortem Degradation of Identifiable Fingerprint Minutiae Over Time

Fingerprints are considered one of the most dependable methods of biometric identification due to their distinct ridge patterns and consistency throughout an individual's lifetime. However, following death, factors like humidity, temperature, and skin slippage can obscure fingerprint clarity, complicating forensic identification. This research investigates how recognizable fingerprint minutiae evolve under postmortem conditions in the Northern Virginia region. Fingerprints were taken daily from cadaver models utilizing ink and fingerprint paper, with minutiae assessed through automated software analysis. A total of ten fingerprints were recorded and analyzed over a span of five consecutive days to evaluate degradation patterns. The count of identifiable minutiae dropped by roughly 33 percent from Day 0 to Day 5, with a noticeable decline in ridge detail beginning around Day 4. Increased environmental humidity seemed to hasten this deterioration by impairing ridge adhesion and clarity. These findings align with anticipated postmortem physiological changes and highlight the impact of both climate and time on fingerprint quality. The study indicates that identifiable minutiae remain relatively stable during the initial three days following death, after which the reliability of identification significantly diminishes. Future research will aim to increase the sample size and investigate additional environmental factors to enhance the accuracy and forensic implications of these findings.

Abstract Name: Conserving Mudpuppies: Mapping and Monitoring an Indicator Species in the Detroit River

Mudpuppies are a salamander species native to the Great Lakes region, and can be found in the Detroit River. They have really porous skin, allowing them to absorb lots of water. Their sensitive skin marks them as bio-indicators, meaning their population size can tell us about the quality of a water body. Higher populations of mudpuppies can indicate a healthy river. After experiencing a decline in mudpuppy populations due to lampricide applications and habitat degradation, The Department of Natural Resources marked this amphibian as a species of special concern. As a result, the Detroit Zoological Society initiated a study in 2009 to monitor mudpuppies. This work is done in Detroit, where youth may be unaware of the mudpuppies' existence and its importance to conservation. The aim of this project is to highlight local conservation work and educate guests of the Detroit Zoo. In this project, we will collect and compile the data and use Esri ArcGIS Pro to analyze and map the data collected by the Detroit Zoo, as well as create educational material. This material will be presented as a poster in the National Amphibian Conservation Center in order to highlight local conservation work.

Abstract Name: Assessment Of Bridge Strikes and Predictive Factors Across Five States Using Regression Analysis to Highlight Bridge Vulnerability

A bridge strike occurs when an over-height vehicle collides with the underside or superstructure of a bridge as it attempts to pass underneath it. These incidents can cause damage to the bridge, disrupt traffic, and pose safety risks to drivers. Between 2012 and 2021, there were about 11,000 to 18,000 crashes each year nationally, leading to nearly 2,200 deaths and 47,000 injuries. This study investigates the critical factors influencing bridge strike incidents across five states: New York, Washington, Illinois, Florida, and North Carolina, with a focus on New York due to its unique infrastructure characteristics, as well as data availability. Lower clearance heights and older age had the most correlation with an increase in bridge strikes in New York City. Using these variables, five bridges in New York City were identified as “high risk”. We aim to understand if this is applicable for bridges in other states and how variability of clearance of height and age across these cities affects strike count. New York State bridge strike data from NYC Open Data is analyzed in conjunction with the University of Wisconsin’s National Data Clearinghouse for Bridge and Tunnel Strikes to quantify strike rates and average clearance heights and ages of bridges in each state. This research employs statistical methodologies, including regression analysis, to determine if low clearance height and bridge age are significant predictors of strike frequency and whether these effects differ across states. By identifying the key predictors and their state-specific impact, this study can be used to find bridges at a higher risk of bridge strikes. Locating these bridges can lead to necessary inspections and renovations, thus lowering their risk of damage and saving millions of dollars.

Abstract Name: The Missing Pieces: An Umbrella Review of Risk and Resistance Factors in Substance Use

Background: The existing literature on risk, protective, and resistance factors is fragmented across separate reviews. It is therefore currently difficult to connect these intersecting ideas with one another and build comprehensive substance use prevention strategies. This review aims to bring these areas together by

systematically organizing what is already known about risk, protective, and resistance factors related to substance use. **Methods:** We conducted an umbrella review of approximately 13,000 articles. Reviews were included if they were published in 2000 or later; reported on a U.S. population, and examined risk, protective, or resistance factors; studied substance use in non-clinical settings. Further, we excluded studies that only focused on alcohol or nicotine, studies that were centered on pharmaceutical or clinical treatment interventions, only focused on a youth-only population, were non-English publications, or studies where the outcome was not substance use. After this screening, approximately 700 articles were moved forward for full-text review. **Results:** We expect a wide set of major themes to be identified. Risk-related themes are expected to include: trauma and adversity, mental health challenges, social marginalization and stigma, family and peer influences, community disadvantage, genetic and biological vulnerabilities, health and medically related exposure risks. Protective/resistance themes are likely to include: school-based prevention programs, family-based interventions, digital and mobile health strategies, community-based programs, psychosocial and behavioral approaches, culturally informed and identity-specific interventions, exercise and wellness programs, policy and system-level prevention strategies. **Discussion:** The next step in this project will focus on extracting and summarizing data from the full-text articles to better understand the current landscape of risk and protective factors and how resistance factors may intersect with these concepts towards reducing the likelihood of substance use.

Abstract Name: A Self-Improving Feedback System for Safer and More Reliable AI-Generated Code

Large Language Models (LLMs) can generate code rapidly from natural-language prompts, but their outputs often suffer from compilation errors, logical mistakes, and security vulnerabilities. Current tools provide static checks or manual prompt-engineering strategies, yet no automated system offers continuous, data-driven corrective feedback. In this project, we analyzed more than 2,000 programming tasks across multiple LLMs and observed compilation success rates ranging from 58%–85%, alongside 39%–60% security-related issues, highlighting the urgent need for more reliable AI-assisted code generation. To address this gap, we developed a neural network that predicts whether a user's prompt is likely to produce code with compilation, semantic, or security errors before the LLM generates the output. When the model flags a high-risk prompt, another LLM tries to understand the risks that can occur and then refines the prompt accordingly. Next, the refined prompt is fed back into the model, which produces new code that is analyzed using CodeQL and KLEE symbolic execution to verify whether the issues are resolved. These results are then added to the training dataset, creating a self-improving feedback loop to improve the Neural Network. Our results show that this automated correction pipeline significantly increases prompt quality and reduces downstream errors. This work demonstrates a scalable and proactive approach to improving the safety, reliability, and usability of AI-generated software.

Abstract Name: CRISPR-Phagemid Systems as an Antibiotic Alternative: Targeting *mecA* to Combat Methicillin-Resistant *Staphylococcus aureus* (MRSA)

Antibiotics have revolutionized healthcare; however, the advent of antibiotic resistance, or microorganisms evolving to resist antibacterial drugs, poses a significant global health threat. If not addressed, this could lead to a “post-antibiotic era” in which ten million people die each year from once treatable infections by 2050. Methicillin-resistant *Staphylococcus aureus* (MRSA) is one such bacterium that has evolved to resist standard antibiotics, including vancomycin, making MRSA infections particularly difficult to treat in hospital settings. MRSA’s drug-resistant genes, such as *mecA*, and its ability to form biofilms create additional challenges for conventional antibiotic therapies. Recent research has explored CRISPR-Cas systems as a potential alternative therapy, using nucleases designed to target essential bacterial genes. These systems are delivered via phagemids, plasmid-bacteriophage hybrids that can be injected into target bacteria in phage particles and replicate within the host bacteria like a plasmid. This review examines current *in vivo* and *in vitro* studies to evaluate whether CRISPR-phagemid systems are a viable alternative to vancomycin and other antibiotics for MRSA treatment. The CRISPR-phagemid systems can overcome MRSA biofilms and specifically target the *mecA* genes, rendering the cells sensitive to standard antibiotics. These CRISPR-phagemid systems also exhibit high specificity, targeting only MRSA bacteria while leaving the rest of the microbiome unaffected. Although further research is required to ensure its safe use in clinical settings, current findings suggest that CRISPR-phagemid systems may offer a promising alternative strategy for the treatment of MRSA infections and other antibiotic-resistant bacteria.

Abstract Name: Determining the Role of Midline Thalamus in Childhood Absence Epilepsy

Childhood Absence Epilepsy (CAE) is one of the most common forms of pediatric epilepsy. Absence seizures often occur many times each day (~200 per day) and are associated with attention problems, depression, anxiety, and memory impairments. Currently, no cure for CAE exists and treatment strategies are limited, and there is little research on the mechanism of seizure generation. Seizures are associated with highly synchronized firing across the brain. Understanding how this synchrony is generated will inform new therapeutic strategies. Our preliminary data demonstrates that the midline thalamus is highly synchronized with multiple surrounding brain structures during seizures. Furthermore, stimulation of midline thalamus evokes seizures in the mouse cortex. These findings motivate us to test the hypothesis that midline thalamus facilitates synchrony generation during absence seizures. We seek to explore the role of midline thalamus in seizure generation by temporarily suppressing neuronal firing in the midline thalamus using chemogenetics. Seizure activity was monitored by implanting EEG headsets on male C3H/HeJ mice and recording brain electrical activity. Baseline EEG recordings were collected before administering clozapine-N-oxide (CNO) and deschloroclozapine (DCZ) to activate Designer Receptor Exclusively Activated by Designer Drugs (DREADDs) to temporarily inhibit neuronal firing and transiently suppress neuronal firing. We then quantified changes in seizure frequency and duration. Brains were then collected for histological verification of DREADD expression fluorescence microscopy. By defining the role of the midline thalamus in seizure synchrony, these experiments may reveal new mechanistic insights and support the development of improved treatments for Childhood Absence Epilepsy.

Abstract Name: Investigating the Immunomodulatory and Tumor-Targeting Effects of Ashwagandha-Derived Therapeutic RH324 in the Glioblastoma (GBM) Microenvironment

Withania somnifera (Ashwagandha) has long been used in Ayurvedic medicine for its adaptogenic and anti-inflammatory effects. Its therapeutic potential arises from its broad natural composition of proteins, amino acids, fatty acids, carbohydrates, vitamins, minerals, and phytochemicals. RH324, an investigational therapeutic developed by ReHeva Biosciences, is a full-spectrum Ashwagandha extract formulated to retain this multifactorial biochemical profile. Unlike single-compound agents, RH324 is designed to act on multiple biological pathways simultaneously and has been evaluated currently for safety and biological activity in patients with advanced non-small cell lung cancer (NSCLC). Building on this foundation, our study examines whether RH324 modulates the tumor-immune microenvironment in GBM and displays tumor-killing capacities. The NF- κ B pathway regulates chemokine expression that shapes myeloid cell recruitment and polarization within the tumor microenvironment. Prior studies show that deleting the p65 (RelA) subunit in myeloid cells can reduce pro-tumor chemokine secretion and alter immune infiltration, suggesting that targeting NF- κ B-related mechanisms may influence tumor-associated immunity. Building on this rationale, our project explores whether RH324, a multifactorial Ashwagandha-derived extract, can modulate immune activity in GBM tissue. At this stage, it remains unknown whether RH324 is cytotoxic to malignant cells, whether it alters immune cell behavior, or which signaling pathways it affects. We expect that RH324 may suppress or activate specific immune populations, with NF- κ B signaling being one potential pathway to be assessed. To address these questions, GBM tissue samples are being collected from operating rooms at University Hospitals in Cleveland, OH and treated with defined RH324 doses. Immunohistochemistry (IHC) will assess changes in cell viability and immune activation, while future single-cell RNA sequencing (scRNA-seq) will help identify transcriptional pathways affected by treatment. In sum, this study aims to define how RH324 may engage NF- κ B-related pathways and contribute to the development of new botanical approaches for shaping tumor immunity.

Abstract Name: BRAFV600E Mutations in Recurrent Papillary Thyroid Carcinoma

Papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer, and although many patients have favorable outcomes, a significant number still experience aggressive tumor behavior or cancer recurrence after treatment. Current diagnostic tools, such as ultrasound imaging and fine-needle aspiration biopsy (FNA), play an important role in identifying thyroid nodules, but these methods often produce indeterminate or uncertain results. When this happens, it becomes harder for clinicians to decide the best treatment approach, which may lead to either unnecessary surgery or delayed care. Incorporating routine BRAF V600E mutation testing into standard clinical evaluation may help improve accuracy in diagnosing and managing PTC. The BRAF V600E mutation is one of the most common genetic changes found in PTC, and research shows it may be closely linked with tumor behavior and treatment outcomes. Using BRAF testing alongside imaging and cytology may give physicians more confidence in identifying high-risk tumors

earlier and determining which patients might benefit from more complete surgical removal, lymph-node evaluation, or closer follow-up after treatment. This approach may help avoid overly aggressive treatment in patients with lower-risk disease. BRAF testing could strengthen long-term care planning by signaling which patients may face a greater likelihood of recurrence or persistent cancer. This supports more personalized care, where treatment decisions are guided not only by tumor size and appearance but also by the underlying biology of the tumor.

Abstract Name: When Lives Are Data: A Java-Based Tool For Detecting Medical Device Software-Driven Vulnerabilities

Remote hackers have discovered healthcare to be vulnerable, seeing medical information as more than ten times more valuable than black market credit card numbers, as they gain access to drugs, conduct fraud with patient insurance, and infiltrate medical devices, harming or even killing thousands of patients. Software attacks, a type of cyberattack, consists of phishing, worms, SPAM, and XSS, which were analyzed to determine that software attacks misguide patients and doctors to reveal private medical information. To address the danger posed by software attacks and foster favorable patient outcomes, the study investigates the following question: how do software attacks intercept private health information, and is there an innovative solution to strengthen cybersecurity, prevent cyberattacks, and minimize data infringement? The study primarily encapsulates a unique tool, designed using Java, that will receive information about a medical device and analyze the cybersecurity strength of the device using specific Food and Drug Administration (FDA) guidelines. Some of these guidelines include checking for the presence of a secure product development framework (SPDF), which indicates that the device can resist major cyber vulnerabilities and threats, has proper design controls, and contains appropriate risk management. The primary methodology for this study was to use the FDA guidelines to thoroughly test a medical device's security, minimize chances of cyberattacks and data infringement, and highlight improvement areas for the manufacturer through the tool's output, raising awareness on the role of robust cybersecurity in preventing patient harm. This study can also serve as a precedent study for points of intervention for researchers in future studies, collectively shedding light on the importance of implementing the novel Java tool in enhancing cybersecurity to progress healthcare.

Abstract Name: The Association between Ultra Processed Foods and Inadequate Sleep in US adults from NHANES, 2005-2018

Background Ultra-processed food (UPF), rich in sugar and fat, could affect sleep quality due to inflammation and hormonal imbalance. However, the population level data is scarce, and the findings are mixed, especially in adult population. Objective We examined associations between UPF consumption and odds of inadequate

sleep (characterized by sleep difficulty and/or inadequate sleep duration: short sleep (<7 h) or long sleep (≥ 9 hours)) among US non-pregnant, non-lactating adults using National Health and Nutrition Examination Survey (NHANES) with a 14-year span. **Methods** We assessed 33,156 adults (aged ≥ 20 y) using up to two 24-hour diet recalls from the NHANES (2005 to 2018). UPF intake was calculated using the NOVA classification system, and inadequate sleep (specifically sleep difficulty, short sleep, long sleep) was ascertained from the self-reported sleep disorder survey. Odds of inadequate sleep (aORs) were compared across the quartile intakes of UPF using population weights-adjusted multivariable general logistic regression. **Results** Of the 33,156 adult participants, 34.9% had short sleep (n=11,576), 11.9% had long sleep (n=3,937), and 24.7% had sleep difficulty (n=8,199). We also found that the highest quartile of UPF, relative to the lowest quartile, is significantly associated with 23% increased odds of short sleep (aOR =1.23, 95% CI: 1.07-1.41; p=0.023), after adjusting for all covariates. The dose-response relationships between higher UPF intake and higher risk of short or long sleep were determined, respectively (both p <0.05). However, no association was found with sleep difficulty (aOR = 1.09, 95% CI: 0.95-1.26; p =0.6185). **Conclusion** We found the dose-response relationship between higher UPF intakes and higher risk for inadequate sleep duration (short or long sleep), indicating that reducing UPF consumption is critical in improving sleep quality via decreased inflammation and enhanced hormonal balance.

Abstract Name: Ford Vs. Labor: Examining the Relationship of Henry Ford and Unions during the Rise of the Ford Motor Company

One of the most influential Americans in the first half the twentieth century is undoubtedly Henry Ford. A man who left a lasting impact not only on the motor vehicle industry but also on the functioning of factory work as a whole. Ford's life has been written about extensively, but a key area is missing. The goal of this project, to analyze the efforts of the burgeoning Ford and his company to combat labor; by using biographies on Henry Ford, Union meeting notes, writings of Ford himself, economic profiles and other pertinent primary material. This project will attempt to express the effort of both labor unions and Ford from the founding of the company in 1903 through the 1910s and resolve by the onset of the Great Depression. By analyzing the relationship of the soon to be great industrialist and the labor movement, this project hopes to shed light on an interesting timeframe of American history. One in which labor had power on the rise and the industrialist was beginning to establish himself. By exploring the dichotomy of industry and man over a century ago, in a time in which the established roles of power were reversed we may gain insight into future and current issues with labor. With Henry Ford being such an influential individual in today's age, examining how he had handle labor relations may better inform the present industrialist and entrepreneur.

Abstract Name: Assessing the Effectiveness of Magnet Schools in Promoting Desegregation: A Systematic Review and Replication Study.

Following the inception of magnet schools in 1968, these programs experienced initial success at meeting their goal: desegregating public schools. However, an abandonment of court ordered desegregation initiatives suggests a shift in the goals of magnet schools. Almost 60 years later, the literature around magnet schools' effectiveness is conflicting and a generalized conclusion is difficult due to each school's unique context. How can we synthesize findings across studies of magnet schools to identify broader trends of integration in school districts? Additionally, how have levels of desegregation in magnet schools changed over time when applying established desegregation measures to current district data? Phase one of this study consists of a qualitative systematic review. A comprehensive literature search was conducted to collect a sample of 51 studies on magnet schools, followed by a qualitative analysis of desegregation in magnet schools over time and the consensus of the literature on desegregation in magnet schools. Phase two is a replication study of three studies selected from the larger qualitative review, utilizing established desegregation measures to analyze current data from three large school districts and evaluate the change in desegregation levels across US magnet schools. Initial results from phase one reveal that literature from the 1980s suggests early success of magnet schools in promoting desegregation. By the 1990s, the literature suggests this success has become selective, concentrated within specific schools, and short-lived. The various desegregation measures from phase two revealed varying magnet school success, but that racial exposure in magnet schools has gradually grown closer to that of non-magnet schools over time. These results suggest that magnet schools may no longer stand out as stronger tools for racial integration than traditional public schools. A reevaluation of how desegregation in public schools is measured and achieved is needed to improve equity in public schools.

Abstract Name: Exploring the Knowledge Gap: Mental Health Crisis Identification Training for 911 Call Takers

Individuals with serious mental illness (SMI) are more likely to come into contact with law enforcement and the justice system. Livingston (2016) found that 25% of people with mental illness have been arrested at least once in their lives. Law enforcement officers often become the primary intervention in handling a mental health crisis, and most mental health-related training curricula (e.g., Crisis Intervention Team (CIT)) have focused on this group. However, the burden to initially ascertain whether an emergency is mental health-related has fallen to 911 call takers and dispatchers, the first first responders. The performance outcomes outlined by the Virginia Department of Criminal Justice Services for compulsory minimum training of 911 dispatchers include managing calls and sustaining composure during situations that may involve mental

health crises. The guidelines emphasize crisis negotiation, instinct, and accumulated experience. This study aims to understand what SMI training options are available and utilized for 911 call takers. An extensive literature search within EBSCOhost, ProQuest, Google Scholar, HeinOnline, and PsycInfo databases was completed using search terms such as "911", "training", "mental health", and "mental illness". Search results yielded 10 studies that directly related to 911 call takers and mental health-related calls. Of the 10 studies, three mentioned trainings that comprised of identifying their own mental health, crisis negotiation, and identifying potential SMI-related calls to transfer to crisis and suicide hotlines. SMI training for 911 call takers is crucial to ensure better outcomes; more research is essential to gain insight into effective training that can help ease the strain on emergency services and inform policymakers and reformers on effective strategies.

Abstract Name: Beyond Evolution: Machine Learning as the New Architect of Protein Engineering

Machine learning has changed how scientists perform protein engineering. Historically speaking, designing or modifying proteins is dependent on directed evolution and high-throughput screening. In these methods, function improvements are mutated iteratively and selectively. These methods, although powerful, are limited by experimental labor, material cost, time, and the constrained ability of human intuition to navigate this high-dimensional sequence space. Recent advancements in deep learning, especially protein language models, generative architectures, and structure prediction networks, emphasize the importance of upstream protein design in computation. This paper examines the shift across three interrelated dimensions. First, machine learning systems are able to identify function sequences that are divergent compared to known evolutionary trajectories, which shows that computational methods can uncover viable designs outside human-derived heuristics. Second, these models compress the wet lab by pre-filtering mutational landscapes, which reduces the number of unique variants that must be physically synthesized and subsequently tested. Third, protein language models demonstrate that amino acid sequences have a kind of statistical “grammar”; that is, context-dependent rules control residue compatibility, folding constraints, and functional motifs. Case studies that looked at antibody affinity maturation, enzyme stability optimization, solvent tolerance engineering, and de novo enzyme generation show that model-guided protein design consistently reduces uncertainty before experimentation and broadens the practical search space beyond what natural sampling alone could do. However, there are still challenges, especially in interpretability, generalization to low-data and low-apriori knowledge biochemical families, and the reliable translation of computational predictions into in vitro and in vivo protocols and performance metrics. In sum, machine learning not only accelerates protein engineering but also bolsters its understanding, which posits computation—not archaic trial-and-error experimentation—as the future of biological design.

Abstract Name: How female sex affects mitochondria in Alzheimer's disease?

Alzheimer's disease (AD) is a neurodegenerative disease that affects more than 6.5 million Americans annually, with approximately 4.2 million of them being female, highlighting the increased risk of AD in women. Mitochondrial maladaptation is a hallmark of AD pathology, characterized by decreased respiration, reduced levels of mitochondrial proteins and altered mitochondrial dynamics. Our goal in this project is to investigate how female sex affects mitochondria in a mouse model of Alzheimer's disease. To answer this question, we used the 5xFAD (on a C57BL/6J background) mouse model, which carries two transgenes (APP and PSEN1) with five AD-causing mutations. Brains were harvested at 2, 4 and 6 months of age, and hippocampi were isolated for further analysis. Mitochondrial function was assessed using frozen mitochondrial respirometry, protein levels were evaluated through immunoblotting, and AD progression was examined through staining. Our preliminary results indicate that 2-month-old females exhibit reduced levels of mitochondrial proteins compared to their male counterparts. The findings from this project will guide future research on mitochondrial involvement in AD.

Abstract Name: Ultrastructural Neurodegeneration in the LGN After Optic Nerve Crush and the Benefits of HDAP.

Traumatic injury to the optic nerve initiates a degenerative cascade extending beyond the retina, producing structural and functional changes throughout the central visual pathway. The lateral geniculate nucleus (LGN), the thalamic relay between retinal ganglion cells (RGCs) and primary visual cortex, is especially vulnerable because its large, vGlut2-positive retinogeniculate terminals rely on mitochondrial stability to sustain high-frequency synaptic transmission. Despite this, the central consequences of optic nerve crush (ONC) at the ultrastructural level remain poorly understood. This project investigates how ONC alters mitochondrial integrity and synaptic architecture within the LGN, and whether a high-density aromatic peptide (HDAP), a cardiolipin-binding mitochondrial stabilizer, can prevent these degenerative changes. Ten adult C57BL/6 mice will undergo unilateral ONC followed by either HDAP (3 mg/kg) or vehicle treatment for 14 days. LGN tissue will be processed for transmission electron microscopy (TEM), and systematic sampling will obtain unbiased, representative neuropil. Quantitative ultrastructural measurements will include mitochondrial density, size, and cristae integrity; bouton area and synaptic density; postsynaptic target distribution; and the frequency of degenerating axonal and dendritic profiles. Preliminary findings indicate that ONC induces features of Wallerian degeneration within the LGN, including shrinking axoplasm separating from the myelin sheath to form submyelin spaces, the appearance of myelin ovoids, and degradation of compact myelin layers. We hypothesize that untreated ONC mice exhibit swollen mitochondria, disrupted cristae, reduced synaptic density, and increased degenerating profiles within the LGN. In contrast, we predict that HDAP will preserve mitochondrial structure, maintain bouton and active zone integrity, and reduce neuropil degeneration. This project will define ultrastructural changes in the LGN after ONC and test a therapeutic strategy that may prevent central trans-synaptic degeneration. These findings will deepen understanding of how optic nerve injury affects thalamic circuitry and may inform future treatments for traumatic optic neuropathy, glaucoma, and related visual disorders.

Abstract Name: Reimagining High School Sports as an Engine of Social Mobility: Structural Barriers and Policy Solutions

Social mobility is understood as movement within a system of stratification (Heath & Li, 2003). Promoting it requires creating opportunities for upward mobility. Current social mobility rates in the U.S. are lower than those in most of Europe (Reeves, 2014). Social origins, higher education, and labor-market advancement have traditionally been seen as the main paths to social mobility. In more recent times, non-traditional pathways, such as sports, have gained interest, although their impact on mobility remains limited for the general population (Eitzen, 2009; Mackin & Alwther, 2011). This poster explores whether high school sports can serve as a more equitable form of mobility by expanding access to opportunities and social capital. Guided by the stages of the policy process, the poster identifies potential changes to high school sports leagues that could increase student participation and promote the development of nationally competitive athletes. It presents policy alternatives to address structural barriers, such as resource disparities, eligibility restrictions, and pay-to-play models that limit access to competitive training. The poster will assess their likely effectiveness, feasibility, and equity of these policy alternatives in reducing structural barriers. Finally, it will propose strategies to increase student participation and create pathways for student athletes from diverse socio-economic backgrounds, aiming to maximize social mobility. Current studies focus on male athletes without acknowledging differing circumstances for female athletes. This comprehensive study is designed to investigate and compare data on accounts of gender and other key identifiers.

Abstract Name: Stigma as a barrier to Opioid Use Disorder (OUD) treatment in Alabama

Introduction: Opioid Use Disorder (OUD) remains a critical public health challenge, and treatment retention is an important predictor of positive health outcomes. Yet, stigma around OUD and medications for opioid use disorder (MOUD) create challenges to treatment continuation. This study aims to assess perceived stigma and its associated factors among individuals receiving MOUD in Alabama. Methods: A quantitative cross-sectional survey was administered to respondents (n=251) from substance use treatment clinics in Alabama. The survey collected demographic information and MOUD history. Using the Substance Use Stigma Mechanism Scale (SU-SMS) and Methadone Maintenance Treatment Stigma Mechanisms Scale (MMT-SMS), patients reported on stigma related to their drug use experiences, including internalized stigma. was collected. Using STATA, descriptive statistics were generated, and linear regression analyses were conducted to examine relationships between predictor variables and healthcare stigma outcomes, with statistical significance set at $p \leq 0.05$. Results: The sample was predominantly White (81.3%) and female (54.2%), with 87% receiving MOUD. Participants reported high rates of experiencing stigma in healthcare settings, including receiving poor care due to drug use history (30.3%) and being denied needed prescriptions because of MOUD usage (29.0%). Regression analysis revealed that women and individuals with higher education levels reported significantly greater perceived stigma. Conversely, Black/Other participants and older adults

(51+) reported significantly lower stigma compared to their White and younger adult (≤ 30) counterparts, respectively. Conclusion: MOUD is an effective treatment that improves the quality of life for many patients, yet stigma remains a significant barrier to accessing this care. To better support patients, healthcare organizations should implement evidence based anti stigma training for staff. Future research should focus on evaluating targeted interventions to reduce healthcare related stigma to ensure equitable access to continuous care.

Abstract Name: Reduced-Channel EEG Biometrics Using Hybrid Machine Learning on P300 Neural Signatures for Secure Authentication

The increasing prevalence of cyber-based attacks and spoofing has exposed an increased need for stronger and more resilient authentication measures across industries. Traditional biometric systems, such as fingerprint detection and facial recognition have become widely adopted. However, these systems remain vulnerable to various forms of physical or digital spoofing. Neural signatures, by contrast, are directly tied to internal cognitive processes and are extremely difficult for an outside actor to imitate, which makes them a promising direction for the next generation of cybersecurity solutions. This research focuses on the integration of Electroencephalography into the field of cybersecurity through the combined implementation of noninvasive neuroimaging techniques and Machine Learning. Electroencephalography (EEG) is a non-invasive neuroimaging technique capable of capturing neural activity through the usage of external electrodes applied to the scalp. EEG has the capability to provide real-time neural data for a variety of diverse applications, such as Brain-Computer Interface (BCI) technology. The safest and most cost-effective implementation of Brain-Computer Interfaces are Scalp-EEG based, which use EEG data to facilitate communication with the Brain-Computer Interface to translate brain activity into commands used for various tasks. This work aims to use EEG data as a form of biometric, and proposes a P300-based Authentication system reliant on Event-Related Potentials to elicit responses in brain activity for authentication, while identifying the prominence of each EEG node in contribution to overall authentication accuracy. The primary research question examines whether the P300 response can function as a reliable biometric identifier and identifies which EEG channels provide the strongest contributions to authentication accuracy. By integrating Event-Related Potential derived features within the authentication pipeline, the proposed system aims to enhance security robustness against conventional spoofing and cyberattacks. Results show strong classification performance and indicate that EEG-based biometrics have significant potential as a secure and robust authentication approach.

Abstract Name: Agrivoltaics: SWOT analysis of current status and future implementation in the United States

Agrivoltaics is the process of co-locating agricultural and solar photovoltaic installations, usually on farmland, with the goal of improving the outputs of both processes. Research in European and Asian countries concerning agrivoltaic operations has reported positive outcomes, raising the potential for implementation in the United States. The US has the highest per capita energy use in the world, and Virginia's electricity demand is increasing 5% annually, largely due to the advent of data centers. In conjunction, many family-farm operations face difficult economic conditions given the precarious nature of the agriculture industry. Implementation of agrivoltaic systems across the US has unearthed political and policy conflicts in many communities concerning the "best" use of agricultural land. This qualitative SWOT analysis examines the strengths, weaknesses, opportunities, and threats present in the current US agrivoltaic practices. Methods being employed include a literature/media review of advocates and opponents of agrivoltaics; a literature review of best practices currently implemented in the United States and other countries; and interviews with current advocates and practitioners of agrivoltaics. Preliminary findings suggest that agrivoltaics improves soil quality, enhances native biodiversity, and improves economic conditions for small farmers. However, adoption faces barriers including high upfront costs, developer practices that conflict with agricultural priorities, and community opposition that usually centers on disputed claims. Future opportunities for agrivoltaics' use within farming communities requires research that produces actionable facts. This study will identify conditions and best practices needed for establishing small-scale agrivoltaic systems in the United States. Towards that end, continued qualitative and quantitative research must be conducted to establish a better understanding of the social, economic, and environmental conditions surrounding these debates. Understanding and implementing these lessons can set a path for the successful deployment of agrivoltaic systems across the United States, particularly Virginia.

Abstract Name: Racial Differences in Actigraphically-Measured Sleep

Background Racial disparities are present in sleep. However, there is a lack of research on racial disparities that include Middle Eastern and North African (MENA) individuals as a racial category. Methods Actigraphy data was collected for a racially diverse sample of 40 participants over two weeks. We ran a multivariate analysis of covariance using age as a covariate, race as the independent variable with four levels of race (Black(n=18), White(n=11), MENA(n=7), and Asian(n=4)), and the best linear fit of total sleep time (TST), wakefulness after sleep onset, and sleep efficiency as the dependent variables. Post hoc analysis using Fisher's least significant difference (LSD) correction for multiple comparisons was performed to determine pairwise associations. Results The results of the main analysis revealed sleep parameters differed by race, Wilks' $\Lambda = .53$, $F(9, 80.46) = 2.64$, $p = .01$. Post-hoc pairwise analysis revealed TST was the only variable that differed by race, $F(3,35)=4.40$, $p=.01$. There was a statistically significant difference between white ($M=385.75$ minutes, $SE=18.22$) and Black ($M=301.65$ minutes, $SE=14.76$) groups ($p<.001$). Differences between White and Asian ($M = 329.53$, $SE = 31.49$) and white and MENA participants ($M = 345.00$, $SE = 23.60$) were not statistically significantly different but may be clinically relevant. Conclusion Racial disparities in TST were evident, with Black participants having the shortest sleep duration followed by Asian, MENA, and then White individuals. While there were no statistically significant racial differences in other sleep characteristics, we may be underpowered to detect group differences with small effect sizes.

Abstract Name: Quantifying the Relationship Between Traffic Activity and NO₂ Levels Using EPA and FHWA Measurements

Nitrogen dioxide (NO₂) is a trace gaseous pollutant formed when nitrogen and oxygen react under high-temperature conditions. This reaction occurs primarily during high-temperature combustion in vehicle engines and naturally during lightning strikes. Because urban areas experience heavy traffic, vehicles have become a major source of NO₂ emissions. NO₂ also contributes to the formation of harmful secondary pollutants. NO₂ reduces air quality, irritates the respiratory system, and is recognized as a key criteria pollutant. Monitoring NO₂ concentrations is essential for understanding environmental impacts and raising awareness of this public health concern. This study analyzes NO₂ levels in major East Coast cities, including New York City, Philadelphia, Baltimore, Washington, D.C., and Richmond. We used hourly Environmental Protection Agency (EPA) ground-based NO₂ measurements combined with hourly Federal Highway Administration (FHWA) traffic counts from 2019 to 2021 to examine how NO₂ surface concentrations vary with traffic volume (vehicles per hour). Although higher correlation coefficients may be observed in more controlled environments, our results demonstrate a clear linear relationship during morning peak hours, followed by a noticeable decrease in the correlation as the day progresses. This pattern highlights the influence of atmospheric chemistry and photochemical processes on NO₂ behavior throughout the day.

Abstract Name: Strongly Independent Set (SIS) Homology for Geometric Lattices

We introduce a new homological theory for geometric lattices that captures structural information beyond the reach of classical constructions. Our approach replaces the traditional chain-based simplicial complex with one generated by strongly independent sets (SIS) of atoms, where each permutation of a set defines a distinct oriented simplex. This construction incorporates the combinatorial geometry of atomic independence into the homological setting, yielding a refined algebraic-topological invariant of lattice structure. We prove that all intermediate homology groups vanish and derive an explicit closed formula for the dimension of the top homology in terms of the dimensions of the SIS chain spaces. We further compare the resulting SIS homology with classical homological frameworks. The SIS invariant not only extends the traditional chain-based approach but also distinguishes geometric lattices that remain indistinguishable under conventional invariants. These findings suggest a broader paradigm in which algebraic topology interacts with lattice theory through atomic independence, providing a finer topological invariant for discrete geometric structures.

Abstract Name: Reviving Space, Reviving Art: Transforming a Historic Inn into a Hub for Dance, Art, and Creative Industry Collaboration

This presentation explores the strategies and mechanisms for transforming an historic building into a year-round, multidisciplinary center for dance, performance, and creative industry collaboration. Inspired by models like Jacob's Pillow and Kaatsbaan Cultural Park, the project aims to build a sustainable arts ecosystem in a rural setting—merging dance education, cultural tourism, hospitality, and community engagement. The project employs a wide range of research techniques, including vital conversations with executives at similar institutions, arts consultants, architectural experts, state representatives, and those most intimately involved with an historic renovation process. The project investigates the architectural, financial, and programming strategies needed to revitalize an existing space and redefine its role in a cultural and economic landscape. The research focuses on a hypothetical project with real-world planning and application. The project commences with a geographical space that reveals some key aspects in key Creative and Cultural Industries and performing arts research on non-urban environments. Maine has been selected as an exemplar, with findings relevant to regions both nationally and internationally. Maine's regional rural landscape presents a surprisingly nurturing context for the proposed interdisciplinary arts venue, demonstrated in recently reported arts and cultural participation data by the National Endowment for the Arts, US Census Bureau, and Cultural Alliance of Maine. More vitally, as explored in the research, Maine's environment serves as a bridge between artists, residents, tourists, and all citizens alike in grounding Maine's rural uniqueness in the creative ways it knows best, spurring creative and cultural industry growth—a cornerstone to a community's vibrancy and overall health. In exposing this narrative and the need for an interdisciplinary venue in a small rural town, the purpose of the research in examining the method for remodeling and redefining a landmark building into an interdisciplinary arts center comes to fruition

Abstract Name: Bridging the Gap Between Perception and Practice: Analyzing Nurses' Roles in Evidence-Based Chronic Pain Management

Chronic pain is a complex medical condition and remains one of the most intricate and costly health conditions to manage. The management of chronic pain is further complicated by its longstanding relationship with opioid therapy. Chronic pain and the opioid epidemic together pose a public health crisis that reinforces the need for evidence-based, non-opioid interventions in the management of chronic pain. Nurses play a central role in chronic pain management. However, each nurse's perceptions, beliefs, and knowledge vary widely, resulting in less optimal outcomes. The focus of this study is to investigate how nurses perceive chronic pain, and how these perceptions shape evidence-based interventions in clinical practice. This project will utilize a mixed-methods descriptive design surveying registered nurses using a

validated survey tool consisting of twenty-eight items. This survey will also examine nurses' understanding of chronic pain physiology, their attitudes toward opioid and non-opioid treatments, as well as the barriers that affect their ability to implement holistic strategies. Demographic and experiential factors will also be used to identify patterns related to education, experience, and nursing specialty. The anticipated findings are expected to identify key contributing factors that influence how nurses assess and manage chronic pain, including their beliefs about opioid use, chronic pain, non-pharmacologic treatments, and the barriers encountered.

Understanding the influences that nurses experience is essential to aligning clinical practice and current recommendations for safe, multimodal pain management. Through the analysis of the gaps, this study has the end goal of highlighting educational initiatives, promoting more effective and holistic approaches to chronic pain care, and the reduction of reliance on opioids. The findings of this study have the potential to strengthen nursing practice by identifying actionable gaps in knowledge and promoting evidence-based, multimodal pain management strategies that support safer, more effective care for individuals living with chronic pain.

Abstract Name: Gender and Belonging: An Exploration of Male Nursing Students' Experiences

Despite gradual increases in male nursing school enrollment, men remain significantly underrepresented in nursing, a field historically shaped by gendered stereotypes and expectations. Such underrepresentation often contributes to isolation, stereotype strain, and identity conflict. This study explores the psychosocial experiences of male nursing students at Southern Nazarene University, focusing on how perceived gender-related challenges influence their sense of belonging, professional identity, and persistence in nursing education. Guided by Bronfenbrenner's Ecological Systems Theory (1979) and the Sense of Belonging Theory (Hagerty et al., 1992) as frameworks, this qualitative research used open-ended surveys completed by seven male students in the SNU nursing program. Thematic analysis revealed six central themes: subtle gender bias, fluctuating sense of belonging, support gaps, stereotype pressure, strong retention commitment, and a pressing need for mentorship. Findings suggest that male nursing students often experience marginalization in clinical settings, lack access to tailored support systems, and face internal and external pressures related to societal perceptions of masculinity. Despite these challenges, participants expressed resilience and dedication to the profession, often motivated by personal and familial goals. This research underscores the need for nursing programs to develop inclusive practices, provide gender-sensitive mentorship, and address structural inequities to support the retention and success of male nursing students.

Abstract Name: Early-Phase Exercise Offsets High Diet Impacts Better Than Late-Phase Exercise in Female Mice

Exercise is crucial for managing body composition, metabolism, and overall health. Several studies show

significant benefits of either early morning or evening exercise. Individuals in the middle-aged and obese demographic are less likely to die if they exercise in the evening rather than in the morning. Other studies show that early morning exercise correlates with weight and fat loss. Compared to evening exercise, early morning exercise also indicates positive trends in sleep quality and heart health. We used the TSE PhenoMaster System to explore how exercise timing influenced metabolic results in C57BL/6 mice. This study assessed the impacts of early versus late active phase running in female mice fed a high-fat diet. Mice were fed a high-fat diet for eight weeks and divided into three groups: control (no exercise), early active phase running (8 PM–12 AM), and late active phase running (2 AM–6 AM). Female mice that exercised during the initial active period showed significantly reduced body weight and fat mass compared to those that exercised later or did not exercise. Gene expression analysis showed reduced leptin levels in early-phase runners, indicating better metabolic control. These studies suggest that the timing of the exercise significantly impacts metabolic health results. Future studies will examine the long-term effects of early versus late phase exercise, evaluate potential sex-specific differences by including male mice, and incorporate progressive resistance protocols further to explore adaptations in fat loss and lean mass growth. These results offer essential information for enhancing rodent exercise models to investigate interventions aimed at obesity and metabolic conditions.

Abstract Name: Predictive Analysis of Insurance Costs and Cost Drivers for A Nonprofit Organization

Nonprofit self-insured organizations often face financial uncertainties due to fluctuations in costs and unpredictable claims. In support of cost saving initiatives for a self-insured not-for-profit, our consulting team developed a predictive analysis model to estimate the company's insurance expenses for 2025. Using three full years of historical claims data, we applied actuarial forecasting models, specifically development triangles, to track cumulative quarterly claims and project for future costs. Inside of R studio using the ChainLadder package, we constructed the triangles using the weighted averages between the quarterly development periods and extending them to predict expenses in future quarters. After receiving a second dataset with updated claims extending through April of 2025, the accuracy of our model was tested by comparing the actual cumulative expenses and the projected expenses inside of the first quarter of 2025. The projections were 96% accurate, displaying strong predictive validity. After validating the models accuracy, we expanded into the two components that became parts of our predictive estimate for expenses inside of the year of 2025; expenses from claims that had been incurred but not yet reported (IBNR) and projected expenses that the company would incur adjusted for a 3% nationwide inflation rate, based on our quarterly development triangles. Our predictive analysis provided insights into cost saving opportunities and cost drivers that ultimately allowed the company to adequately maintain their reserves and plan more effectively for future claims expenditures.

Abstract Name: Integrating Mechanistic Modeling and Machine-Learned Dynamics to Characterize the p53–MDM2 Tumor Suppressor Feedback Loop in Colon Cancer

The p53 protein is a tumor suppressor that activates DNA repair pathways or triggers cell death, preventing cancer formation in human cells. The p53 protein is controlled by MDM2, a regulatory protein that maintains p53 levels when conditions are normal. In various cancers, including colon cancer, this feedback loop is disrupted, allowing damaged cells to continue dividing, as p53 is unable to regulate. Current mathematical and computational models fail to capture the variability observed in cancer systems and capture the behavior of the p53-MDM2 system. This research project focuses on developing a computational model that allows for accurate showings of the dynamic behavior of the p53-MDM2 feedback loop in colon cancer. The model focuses on two approaches: traditional mechanistic equations that represent biochemical interactions, and machine-learned components that account for additional regulatory influences. This model is trained on publicly available time-series gene expression and protein-level data, with the goal of identifying where mechanistic assumptions break down and which regulatory effects may be present in cancer cells. The model will allow for improved predictions on how p53 levels rise and fall under stress, identification of unexplained nonlinear behaviors, and simulations showing how potential therapies may influence the system. This project allows for a flexible and interpretable framework for identifying a key cancer signaling system. By integrating biological knowledge with modern computational methods, this model aims to offer insight into why the p53-MDM2 loop behaves differently in cancer and how those differences may inform therapeutic strategies.

Abstract Name: Comparative Assessment of Wasatch Front Pollutants: Mortality Risk and Toxicity

Exposure to air pollutants, fine (PM_{2.5}) and coarse (PM₁₀) Particulate Matter, and Ozone (O₃) is associated with an increased risk of all-cause mortality, deaths from any natural cause. Utah expresses concern as its arid climate worsens air quality from natural and anthropogenic sources including vehicle emission, mining and processing, and home heating. The dry lakebed of Great Salt Lake (GSL) especially serves as a major emitter of windblown dust across the Wasatch Front. GSL remains the primary source of PM₁₀ emissions with now, increasing O₃ and PM_{2.5} concerns and levels. In this work, we compare air quality trends to their health outcomes; our analysis focuses on quantifying the pollutants and identifying potential dust sources. Meta-analyses show that for every 10 µg/m³ increase in daily PM₁₀, mortality rises about 0.41%, while a 1-hour spike of 100 µg/m³ increases by 0.17%. During 2023-2024, air monitoring data from Environmental Protection Agency (EPA) recorded mean concentrations of 0.074 ppm Ozone (O₃), 19.8 µg/m³ PM₁₀ and 7.46 µg/m³ PM_{2.5} across Utah counties, resulting an approximate 21 ± 7 attributable deaths annually. We calculated that roughly 166 GSL dust events per year would be needed to produce a similar health impact for all pollutant exposure. Dust deposited in communities also contain metal of concern for human health. Due to its high oxidative potential and elevated arsenic and lithium levels, GSL dust is more chemically reactive and toxic than other regional playas in The Great Basin. Preventing dust emissions from the lakebed may decrease health risks from dust in the Wasatch Front.

Abstract Name: From Notes to Noticing: Measuring Elementary Students' Metacognitive Skills with Digital Science Notebooks

As the U.S. strives to remain competitive in STEM, there is a growing emphasis on equipping students with critical thinking skills and the ability to apply content knowledge innovatively, aligning with NGSS Standard ETS2.B on evolving societal needs. In science education, metacognitive thinking bridges theory and practice, enabling fifth graders to progress from guided reflection to independent planning, monitoring, and evaluating problem-solving approaches. Students with strong metacognitive skills can better understand scientific principles, assess their learning, and refine experiments. It is essential to explore strategies that effectively enhance metacognition and promote deep engagement with science. One promising yet less-examined method is the integration of digital science lab notebooks, which offer students a space to document observations and engage in reflective thinking. My research question, "How well do digital science lab notebooks measure a student's metacognitive skills compared to other methods of assessment in elementary school?" investigates whether these digital tools foster a deeper understanding of scientific concepts. To address this question, the study employs a case study methodology, examining two fifth-grade classes, a sample size of approximately 40 students, who will complete a Qualtrics multiple-choice pre-test and post-test to measure content knowledge, as well as Children's Perceived Use of Self-Regulated Learning Inventory (CP-SRL) surveys to measure metacognitive awareness. Using multimodal discourse analysis, I examine students' responses in their Arduino Digital Science Notebooks to evaluate whether these tools foster more frequent monitoring, regulation, and reflection than traditional measures. While results are preliminary, the structured format suggests stronger metacognitive skill development in elementary students. Thus, I anticipate that using digital lab notebooks will significantly strengthen 5th graders' metacognitive skills by providing structured opportunities for reflection, self-monitoring, and active engagement with scientific concepts.

Abstract Name: Breaking the Mold: How Poetry Can Reach Beyond Words in K-12 Curricula

This article explores poetry education within the Virginian high school curriculum, arguing that these curricula should consider including lessons and examples of poetry with more direct visual elements so as to better engage students. Visual poetry, or poetry that combines graphic and visual elements in its message, uses things like variations in spacing, or even different word and letter sizing. Because of these visual elements, this type of poetry serves as a more accessible entry point for less advanced readers, and thus may better reach students and help them to enjoy the benefits of poetry. Currently, there is little research on visual poetry, especially within the United States and visual poetry is not taught as a unit in VA high schools or specifically focused upon as a method of engagement by K-12 ELA teachers. Yet, visual poetry is popular online, reaching younger students through social media and some literary magazines. This article seeks to shed light on the potential of this form to help students develop a love and appreciation for poetry. By examining several well-known figures for visual poetry, examples of social media engagement with visual poets, and an informal observation conducted at my pre-service teaching practicum, this essay argues that visual poetry should be considered as a useful springboard toward more traditional poetic devices and understanding of poetry's general intents of expression.

Abstract Name: Exploring Gendered Differences of Youth Located in Public Housing

Health care providers use behavioral health risk assessments to identify trends in youth behavior which are used for immediate intervention (Sappenfield O, Alberto C, Minnaert J, et al,2024). However, risk assessments are needed to identify ways in which gender influences the behavior of youth. Understanding the specific influences of gender on youth behavior allows practitioners in behavioral health settings to develop more appropriate interventions that meet the specific needs of youth. To address this problem, these research questions were posed, what are the differences in behavioral health between boys and girls. Are there significant differences in the participation in delinquency behavior, maternal and paternal supervision/encouragement, and emotional restraint between boys and girls? This study employed secondary data analysis of the Adolescent Health Survey of Hampton Roads conducted in 2023. The final sample was 378 participants with an average age of 14.8. The participants' ages ranged from 10 to 17 years old. Eighty-three percent of the participants identified as African American. Data was collected using a questionnaire that included demographic variables and self-administered standardized scales including The Weinberger Adjustment Inventory Emotional-Restraint subscale (Weinberger,1990), The Self-Reported Delinquency Scale (Elliot,1987), and the Parental Attitude Measure (Lamborn et al,1991). The preliminary analysis revealed statistically significant differences between boys and girls. Boys had a higher level of delinquent behavior ($M=18.48, SD=8.42$) compared to girls ($M=15.91, SD=4.52$) [$t(321)=3.25$ $F(30.61), P=.001$]. Girls had higher levels of emotional restraint ($M=45.74, SD=7.1$) compared to boys ($M=42.84, SD=7.91$) [$t(286)=-3.26$ $F(.459), P=.001$]. Girls also had a higher level of maternal supervision ($M=16.21$ $SD=3.83$) compared to boys ($M=15.11, SD=4.36$) [$t(320)=-.679$ $F(2.70), P=.009$]. These results are evidence of the need for gender-specific behavioral health risk assessments. Implications for further research will be discussed.

Abstract Name: Charge Transfer vs. Electrostatics: The Distribution of Sigma-Hole like Sites on Polarized Alkali Earth Metals and Implications for Bonding in Small Clusters

The experimental and computational studies of the structure and bonding in alkali metal halide dimers and oligomers was historically important in our understanding of molecular cluster formation. That understanding of clusters continues to be important in modern discussions of structure prediction. In examining the bonding in heterodimers combining alkali halides with bases such as ammonia and a model base of the form :E-H to avoid secondary interactions involving the substituents, we found that the linear dimer, F-M *** E-H – which is expected for normal sigma hole interactions – is unstable relative to an angled or no linear structure. Such a system has not been rationalized from molecular orbital or valence bond theory to date, and we draw on those theoretical frameworks in this study, yet we find most remarkably that a detailed analysis of the computed

surface potentials of the metal halide systems, hence evolution of the M atoms in their abilities to participate in sigma hole interactions, offer a surprisingly simple rational for this anomaly in the bonding pattern of the heterodimers as M gets larger. We discuss these observations in our poster presentations as well as the more fundamental question of the link between electrostatics and charge transfer in these compounds, and vantage points of the sigma hole concept and standard bonding models in accounting for trends in highly polarized complexes.

Abstract Name: The Role of Fusion Proteins in the Progression of Pilocytic Astrocytoma to Glioblastoma

Pilocytic astrocytoma (PA) is the most prevalent pediatric brain tumor affecting children from the ages of 0-19 years old. Though PA itself is a benign WHO grade 1 tumor, in rare cases it has been shown to progress to a more aggressive and malignant glioblastoma which is WHO grade 4. Glioblastomas (GBM) have a significantly worse prognosis and are much more difficult to surgically treat. Because PA is typically treated with surgical resection, there is a significant gap in research regarding the molecular mechanisms behind both PA formation and the progression to GBM. This gap highlights the need to investigate novel oncogenic factors such as fusion proteins, which have recently been established as key drivers of cancerous formation in other types of tumors. Gene fusion events, caused by structural variations of DNA within the genome, produce these fusion proteins with altered functions. St. Jude Cloud Genomics Platform (SJCGP) is a database hosted by St. Jude Research Hospital which has de-identified patient sequencing data. CICERO is a software that uses the available SJCGP RNA-seq data to predict structural variations, specifically gene fusions. Fusion events found in PA and GBM samples will then be isolated and compared to find genetic similarities between the two cancer types. These specific gene fusions will then be translated into fusion proteins and characterized to determine the altered function. Overall, this comparison will allow for the discovery of any specific fusion proteins which may drive the transition from PA to GBM. We expect to find at least one shared fusion protein from the CICERO output for both PA and GBM, which may indicate its role in PA progression. Fusion proteins found to drive this progression may be used as therapeutic targets in the future as an alternative to surgical resection.

Abstract Name: Surfactant Replacement Therapy in a Rodent Model of Acute Respiratory Distress Syndrome

Introduction: Acute Respiratory Distress Syndrome (ARDS) is a severe form of lung injury in which inflammatory damage causes fluid accumulation in the lung, disruption of gas exchange, and loss of functional surfactant. Reduced surfactant leads to increased alveolar collapse, contributing to fluid buildup in the lung, lack of oxygen in the blood, and respiratory failure. Current therapies, such as mechanical ventilation and various inhaled drugs, treat many symptoms of ARDS but do not directly correct surfactant dysfunction. Synthetic and animal-derived surfactants are used clinically in premature infants, yet no inhaled surfactant treatment exists for adults with ARDS. This study evaluates a dry powder synthetic surfactant

aerosol for its ability to improve lung mechanics and gas exchange in a rat model of lipopolysaccharide (LPS)–induced ARDS. Methods: Sprague–Dawley rats were given intratracheal LPS or saline, allowed to recover 24 hours, and then received either sham intubation or 5 mg of a spray-dried, excipient-enhanced phospholipid surfactant via a custom air-jet dry powder insufflator, as described by Pangeri et al (2023). After an additional 24 hours, lung mechanics, arterial and venous blood gases, bronchoalveolar lavage (BAL) fluid, and lung tissue were collected. Results: IVIS imaging demonstrates distribution of the aerosolized surfactant throughout LPS-injured lungs, indicating effective delivery to distal airspaces. Additionally, BAL protein measurements show a trend toward increased total protein in LPS-injured controls, suggesting decreased alveolar protein leakage, although these changes are not yet statistically significant. Blood gas analysis indicates improved oxygenation and reduced hypoxemia in surfactant-treated animals. Overall, these data suggest that dry powder synthetic surfactant can be efficiently delivered to the injured lung via aerosolization and may attenuate inflammation- associated barrier disruption. Future work will include increasing dosing frequency, extending the observation period, and expanding BAL protein, cytology, blood gas, and histologic analyses to define the therapeutic impact of this formula.

Abstract Name: Understanding how Traffic Levels Influence the Distribution of Tire Wear Particles in Surface Soils at Two Roadside Agricultural Sites

Microplastics delivered to roadside soils by vehicle traffic reduce agricultural productivity. Previous research lacks information on how traffic rates impact tire wear particle concentrations in soils in the Midwest. Through our research we aim to observe how variations in road traffic levels at two sites in Whitewater, Wisconsin affect the amount of tire wear particles dispersed into roadside agricultural soil. We also hope to quantify how tire wear particle concentrations change in a transect away from the roads. At two sites, one with low traffic rates (Anderson Rd) and one with high traffic rates (WI-59), 5 cm deep soil samples were collected along a transect 0.25, 0.5, 1, 3, and 5 m away from the road. We have also sieved each of the ten samples to be greater than 100 micrometers, but less than 1000 micrometers because that's the size range of most tire wear particles. We digested organic matter in the soil samples using 30% hydrogen peroxide for 72 hours. We still have yet to perform a two-step density separation to isolate tire wear particles (1.2-1.4 g/cm³) from each soil sample. To do this, we would collect the particles that float in a zinc chloride solution (1.7 g/cm³) and sink in a sodium chloride solution (1.2 g/cm³). We predict that the soil samples collected at the higher traffic site will contain more tire wear particles than the samples collected at the site with less traffic. As the distance from the road increases, we expect there to be an exponential decrease in tire wear particles. In the agriculturally dominant Midwest, it is important to prevent soil and plant contamination by understanding tire wear distribution. The results of this research will be crucial to protecting agricultural practices from the harmful effects of microplastics.

Abstract Name: Predictive Modeling of Readmissions and Quality of Care in Type I and Type II Diabetes Patients Using Hospital Inpatient Data

Diabetes is a growing concern as in 2024, around 1.2 million people were diagnosed with Type-I/Type-II diabetes in the United States. Understanding of the disease will help to cure it at an early stage. This research analyzes how the characteristics of diabetes patients contribute to understanding diabetes complications. The factors which influence the type of care received by an individual in a specific facility are identified. It allows for the development of benchmarks to determine the quality of care for type-I/type-II diabetic patients. It also assesses how hospitalised diabetes care affects the future health of diabetes patients. Based on the identified characteristics in the 'Diabetes 130-US Hospitals...' dataset, predictive models can be developed by employing AI/Machine techniques. For this purpose, a database of diabetes inpatient encounters from 130 hospitals in the United States between Jan-1999 to Dec-2008. The research includes 50+ features collected from over a decade of inpatient service. The approach to classifying the outcomes of patients who may be admitted to the hospital again will take the form of a classification strategy that establishes three categories: (1) No Readmission; (2) Readmitted within 30 days; and (3) Readmitted at any time after 30 days. The focus of the study will be on the second category. Two modeling approaches are developed: (1) a logistic regression model to provide a baseline for interpretable models, and (2) gradient boosting classifiers for capturing Non-Linear Relationships within the High Dimensional Feature Space. The preliminary results indicate that the gradient boosting classifiers performed better than the Logistic Regression models to predict Readmissions, especially for early Readmissions. The coefficients from the Logistic Regression Models indicated that the test results of HbA1c, number of laboratory procedures, and prior emergency department visits were significant predictors. Detailed results will be presented in the conference.

Abstract Name: Selectivity and Long-Term Proliferation Suppression by the Synergistic Combination of Vitamin C and an H₂O₂-Activated Prodrug Across Diverse Cancer Models

The complexity and heterogeneity of cancer limits the efficacy of single-agent therapies, emphasizing the need for rational combination strategies early in drug development. The Peng group recently developed FAN-NM-CH₃, an H₂O₂-activated nitrogen mustard prodrug that generates a potent DNA-alkylator upon reaction with intracellular hydrogen peroxide. This activation blocks DNA replication and induces apoptosis, enabling selective targeting of cancer cells with dysregulated redox homeostasis. In this study, we systematically evaluated the selectivity and long-term proliferative impact of combining ascorbic acid with FAN-NM-CH₃ across multiple cancer models, including triple-negative breast cancer (TNBC) and glioblastoma (GBM) cell lines, as well as matched normal epithelial cell lines. Mechanistic studies indicate that catalase, a key H₂O₂-scavenging enzyme, contributes to differential sensitivity by limiting ROS-mediated prodrug activation in normal cells. We determined 48-h IC₅₀ values for each agent, identified the Maximum Safe Dose (MSD) of vitamin C, and measured changes in prodrug IC₅₀ in the presence of the vitamin C MSD. Fold-change analysis revealed strong synergy, with the combination significantly reducing IC₅₀ values in TNBC and GBM cells while sparing normal epithelial cells. To assess whether short-term cytotoxicity translated into lasting growth suppression, we performed clonogenic assays. The vitamin C + FAN-NM-CH₃ combination nearly eliminated long-term colony formation in MDA-MB-468 cells, whereas catalase and deferoxamine (DFO) partially rescued survival, consistent with an ROS-dependent activation mechanism. Overall, these findings demonstrate that ascorbic acid markedly enhances both the anticancer potency and the selectivity of the H₂O₂-activated prodrug. Combined with previously demonstrated in vivo tumor regression across three breast

cancer models, these results support advancing this strategy toward preclinical evaluation in patient-derived xenograft (PDX) TNBC models.

Abstract Name: Hot-Wire Anemometer Calibration for Jet Engine Intake Flow to Support Greenhouse Gas Emissions Reduction

The aviation industry accounts for 2.5% of global CO₂ emissions, more than 180 countries. Although jet emissions per plane have decreased, rising flight demand has increased total emissions. This highlights the need for more research into aviation emissions reduction. A hot-wire anemometer is an important device for emissions studies. Its high sensitivity and fast response times make it optimal for air velocity measurements in jet engine intake studies. Accurate intake air velocity data enables calculation and adjustment of the jet engine's fuel map. The intake air velocity and known intake cross-sectional area are used to calculate the mass-flow rate. This shows how much air flows into the engine per unit time. From this, the optimal amount of fuel for reduced emissions can be set. Calculated intake pressure is also used in fluid dynamics simulations. This data improves predictions of combustion and air flow in the engine. Engineers can then optimize engine design to reduce emissions. The expected result of this experiment is a calibrated relationship between hot-wire and real air velocity. This will enable more accurate engine models and fuel-map adjustments for efficiency and reduced emissions. Therefore, a benchtop experiment was designed to calibrate the anemometer under variable air flow velocity conditions. To create the controlled air velocity environment, a variable velocity fan and a variable DC power supply were utilized. This system will create a constant, calculable airflow to create a reference wind velocity to compare to the anemometer.

Abstract Name: Marine Energy powered Desalination using Membrane Distillation

Island cities struggle with high-salinity groundwater compounded by scarce energy resources. Additionally, island nations and their populations are prone to natural disasters such as hurricanes, in which a stable energy source to provide clean drinking water is a necessity. These conditions make island nations prime candidates for ocean thermal energy converters (OTECs), which harness the difference in temperature between the warm surface layer and the colder, deeper layers (a thermocline). The purpose of the project is to explore the potential of thermocline energy for freshwater production and thermal desalination via membrane distillation.

The team plans to use existing marine energy concepts in a novel way. A market will be identified for the planned design, followed by an evaluation of the system's near-term market potential, taking into account prospective end users and key stakeholders. Lastly, the team will create a prototype and test relevant metrics, such as power output and efficiency, to determine whether the design is suitable for the identified communities. The findings from the project will provide insight into the feasibility of implementing a thermocline energy OTEC system for desalination in tropical communities, an economic overview of the market, and input from critical stakeholders for future projects.

Abstract Name: Metabolic Profiling in Orbital Adipose Tissue in TED in Response to Teprotumumab

Introduction: Thyroid Eye Disease (TED) is an autoimmune disease most commonly associated with Graves' Disease. It is characterized by the expansion of orbital fat and inflammation leading to dry eyes, pronounced proptosis, optic nerve compression and ultimately vision loss. The pathophysiology of this disease involves thyroid-stimulating hormone receptor (TSHR) and insulin-like growth factor I receptor (IGF-IR) being expressed in orbital fibroblasts causing a signaling cascade. Ultimately, this leads to inflammatory and tissue remodeling. Teprotumumab was recently approved for treatment and targets IGF-IR with significant outcomes such as 35% fat volume reduction. Currently diagnoses are made using clinical presentation and imaging and identifying molecular biomarkers could aid in this diagnosis process. Metabolomics offers an opportunity to identify dysfunction in metabolic pathways that lead to these diseased states and enhance current treatment options. **Methods:** In the present study, we used a targeted metabolomics approach using liquid chromatography-mass spectrometry (LCMS) to quantify 134 metabolites across orbital adipose tissue. Samples included non-TED controls (n=13) and TED patients both treated with teprotumumab (n=13) and not (n=9). Normalization to account for weight of tissue was completed. **Results:** We found distinctive metabolic alterations in both in control versus untreated TED patients and when comparing untreated TED patients with treated TED patients. 28 metabolites significantly changed in untreated TED compared to controls, with 15 having increased and 13 decreased. When untreated TED patients were compared to treated TED patients 24 metabolites were significantly changed with 19 having decreased and 5 increased. This includes four metabolites that were restored to normal levels with the addition of teprotumumab.

Abstract Name: Perspective of Westminster College Students on Social Theories of Justice and Crime

There are approximately two million people being held in custody across the United States. Now more than ever, understanding justice and crime and the ways in which society perceives them is of the utmost importance. This study uses Q-Methodology, which permits the scientific study of subjectivity, to explore the opinions of a group of Westminster College students and opinions they have on statements pulled from criminology and sociology theorists. The study found three distinct and theoretically supported factors which

viewed criminals and justice in three different ways. The factors parallel already existing viewpoints people have in politics and the criminal justice field as a whole. This study can be used in reflecting upon both historical and ongoing trends and policy decisions in the criminal justice world, alongside analyzing the issues present within society such as poverty, homelessness, and prison overcrowding.

Abstract Name: Rehabilitative Efforts in Prisons - What Has Been Done and What is Needed?

Previous research by Bain (2019), Ward and Maruna (2007), and Robinson and Crow (2009), have made efforts to determine what supports offender rehabilitation. Research has largely focused on discussing differing models and how they align with rehabilitative theory. However, rehabilitation cannot just revolve around one type of treatment, therapy, or program; not every offender responds in the same way and with the same rate of success. This can be due to differences in what is offered and what is needed. This paper provides a thorough review of literature in the field of rehabilitation to consider individual need and responsiveness. It provides for a historical review of rehabilitative work supplemented by evidence from lived experience and academic expertise, beginning with the Quaker movement in the mid 1800's through current practice in the United States. In sum, this research is intended to provide a framework for future studies into offender rehabilitation and a successful desistance. It is essential to efforts to reduce crime and the numbers of victims in society.

Abstract Name: Effects of Plant Diversity on Insect Communities in Stormwater BMPs

Our project examines the effects of plant community structure on insect diversity in stormwater Best Management Practices (BMPs). BMPs are in-ground structures used to collect and filter stormwater runoff to reduce environmental impacts like water pollution, erosion, and flooding. BMPs may be covered with a variety of different plant communities, from mown grass with unmanaged opportunists to carefully managed native plantings. Small green spaces within urban areas support pollinators and other beneficial insects. Within a green space, the diversity of plant species and availability of floral resources can affect the types and abundance of insects supported. Therefore, the structure of the plant community growing on BMPs will likely affect the insect community present. We assessed the plant community in each BMP using four randomly placed 1-m² quadrats. We identified plant species in the quadrats using PlantNet to calculate species richness and counted stems of each species to assess relative abundance. We noted all species in-bloom and measured plant height (cm) at three points in each quadrat. We assessed the insect community in each BMP using 5 sets of yellow, blue, and white bee bowls suspended at vegetation height from step-in fence posts, deployed for 24 hr. Collected insects were preserved in 70% EtOH and identified to family. We assessed the relationship between plant species diversity, richness of species blooming, and insect diversity. We expect to find a

positive relationship between both the species richness and the number of species blooming and the number of insect families captured in each BMP. Additionally, we will repeat these samples monthly from Mar-Oct 2026 to determine how these relationships change seasonally. This information can be used to manage BMPs in ways that will maximize conservation benefits.

Abstract Name: Heart Rate Variability and PROMIS Outcomes in Pediatric Rehabilitation

Chronic pain affects up to 30% of children and adolescents, impairing quality of life. Within a biopsychosocial framework, multidisciplinary pain management remains essential. The Monitored Augmented Rehabilitation System (MARS) delivers individualized, technology-assisted exercise therapy while simultaneously capturing physiological metrics, including heart rate (HR) and heart rate variability (HRV). This study evaluated whether routine pain management interventions incorporating MARS were associated with improvements in self-reported outcomes measured by PROMIS domains and physiological measures of autonomic regulation. Twenty pediatric patients with chronic pain diagnoses completed two MARS sessions at least four weeks apart. HR and HRV data were recorded using a validated H10 Polar Heart Rate chest strap during 3-minute intervals: rest (HRV-0), the first 3 minutes of exercise (HRV-1), the middle 3 minutes of exercise (HRV-2), and the final 3 minutes of exercise (HRV-3). Patients returned ≥ 1 month later to repeat the initial session. Paired-sample t-tests evaluated changes between time points ($\alpha = 0.05$), and effect sizes were calculated using Cohen's d. PROMIS domains (Anxiety, Depression, Fatigue, Pain Behavior, Pain Interference, and Pain Intensity) and CES-D scores were collected pre- and post-intervention. Paired t-tests and Wilcoxon signed-rank tests assessed pre-post changes, and Spearman's rank-order correlations examined relationships between changes in resting RMSSD and PROMIS scores. Pain Behavior T-scores significantly decreased post-intervention ($p = 0.009$), with no other PROMIS or CES-D domains showing significant change. RMSSD increased during the 6-9 minute exercise segment in Session B relative to Session A ($p = 0.037$), suggesting improved parasympathetic modulation. No significant associations were found between HRV changes and PROMIS ($p > 0.05$). MARS-based rehabilitation was associated with reductions in pain behavior and modest improvements in autonomic regulation during exercise. However, HRV changes did not correspond with self-reported outcomes, suggesting that physiological and subjective recovery may occur on different trajectories in pediatric pain rehabilitation.

Abstract Name: Defense Approaches against Adversarial Attacks on Remote Sensing Applications

Deep learning based models are utilized in remote sensing systems to interpret satellite imagery, classify land, and monitor objects. However, these deep learning models are vulnerable to adversarial attacks—small input perturbations that can cause critical misclassifications. This work explores the impact of adversarial attacks, e.g., Fast Gradient Sign Method (FGSM) attack, on satellite images, e.g., UC-Merced Land Use Dataset. We

perform a comparative study of existing defense strategies, including Projected Gradient Descent-based adversarial training, gradient masking, detection-based classifiers, and input transformations such as Gaussian and Median filtering. We propose an input transformation-based dual-stage defense method combining Gaussian and Median filtering against adversarial attacks. We improved adversarial testing accuracy (ATA) to 66.90% while maintaining 75.00% clean accuracy using Gaussian filtering ($\sigma = 2$) with 5×5 Median filtering without fine-tuning the underlying model. Additionally, gradient masking (with a noise of 0.10) also boosted robustness, increasing ATA to 54.05% with a clean accuracy of 75.24%. We also apply an effective ensemble surrogate models-based black-box attack, iterative FGSM, and achieved an attack success rate (ASR) of 60.00% compared to traditional FGSM (ASR = 49.29%), demonstrating stronger transferability. Even after applying the combined filter defense, the attack remained effective with an ASR of 56.62%, highlighting the robustness & practicality of multi-step ensemble attacks in black-box settings. Our findings reveal the strengths & trade-offs of each defense, providing insights for enhancing robustness in remote sensing systems against adversarial attacks.

Abstract Name: The Gaussian Curvature of Superminimal Immersions in the Round 4-Sphere

Through this research project in Differential Geometry, we investigated the existence of negatively curved minimal surfaces in spheres, particularly in S^4 , which is the unit sphere centered at the origin in the 5-dimensional R^5 space. We studied the following problem: Is there a negatively curved, closed, minimal surface in a round sphere? The problem has remained open for decades, since there are serious obstructions, given by the positive curvature of the ambient space, to the existence of negatively curved minimal surfaces in spheres. Bryant and Hano have invented methods to generate minimal surfaces in spheres with semi-explicit twistorial constructions. We studied new methods to understand the Gaussian curvature of Bryant-Hano surfaces. We show that no smooth superminimal immersion in S^4 can have strictly negative Gaussian curvature, as any such immersion of genus g , greater than or equal to 2, must have at least one umbilic point. We studied an alternate proof for the following: No smooth superminimal immersion in S^4 can have strictly negative Gaussian curvature. This is a corollary of the following theorem: For a smooth superminimal immersion into S^4 , the Euler characteristic of the domain surface is strictly greater than zero, or the immersion map, ϕ , has at least one umbilic point.

Abstract Name: The Impact of Linguistic and Cultural Contexts on Elementary Science Education

The National Science Teaching Association emphasizes that STEM should be taught through hands-on, interdisciplinary projects that connect classroom learning to real-world applications. STEM learning also equips students with essential skills such as problem-solving, collaboration, and critical thinking. Given its importance in K–5 education, effective STEM instruction is crucial for student success. However, culturally

holistic science instruction remains uncommon in many classrooms. To address this gap, we examine the impact of integrating students' cultural experiences into science curricula and learning activities. In this study, culture is defined as the customs, arts, social institutions, and achievements of a particular social group. Specifically, our work aims to identify the cultural assets of students in the Greensboro community and investigate how leveraging these assets can directly impact success in science education. Grounded in a "whole child" approach, this framework invites students and educators to engage in STEM learning while recognizing and valuing the cultural strengths each group contributes. Using comparative methods to analyze students' science journals alongside pre- and post-surveys, this case study examines the effects of implementing this approach. For this project, we designed a science lesson that embedded local cultural elements through field trips and active learning experiences within students' own communities. We then analyzed the resulting data to measure its impact on student outcomes. Our findings suggest that students benefited from holistic science instruction, developing deeper connections with the content and an enhanced ability to communicate their scientific understanding.

Abstract Name: Exploring Undergraduate Biology Students' Vaccine Education and Communication: A Qualitative Interview Study

I aim to explore undergraduate biology students' vaccine attitudes and experiences with vaccine communication and vaccine education to provide recommendations for improving vaccine education. My research questions are: What are undergraduate biology students' current knowledge, attitudes, and beliefs about vaccines? How are undergraduate biology students communicating with others about vaccines? In what ways are undergraduate biology students learning about vaccines in their biology courses, and how do they think vaccine education can improve? To prepare students for having careers in science and healthcare, biology scholars identified that students need science knowledge and the ability to communicate science. Despite being regarded as a key competency of the undergraduate biology curriculum, the teaching of science communication is largely absent from these programs, and even more so within the teaching of communicating culturally controversial science topics (CCSTs). Vaccines are an example of a CCST, as scientists recognize vaccines as an important medical advancement, yet vaccines also carry mistrust within the public. It is important for biology educators to have information on student knowledge, attitudes, and communication about vaccines so they can implement effective instruction. However, educators currently lack this information. I am recruiting 30 participants to participate in 60-minute semi-structured interviews. Prior to interviews, participants will complete a pre-interview survey that gauges their vaccine knowledge & education history. Interviews will be audio-recorded and transcribed. Inductive and deductive content analysis with constant comparison methods will be used to identify themes, and I'll create a codebook to describe these themes. A second researcher will analyze a subset of interviews to determine the codebook's interrater reliability. Currently, I have conducted three interviews. Although data are preliminary, participants infrequently communicate vaccines due to feeling underprepared. Participants feel underprepared with communicating vaccines due to a lack of vaccine instruction in biology courses. However, participants display positive attitudes towards vaccines.

Abstract Name: The Future of Poetry: Transliteracy and Literary Practice in the Digital Age

The digital age has revolutionized the conditions of cultural production and reception; people create, circulate, and encounter literary expression in forms that are far beyond conventional expectations of what literature looks like or where it belongs. Existing scholarship indicates that the newest generations spend more time engaging with digital spaces rather than traditional forms of media. Yet despite extensive study of digital media's cultural and psychological effects, few accounts have analyzed the lived practices of young readers and writers who intersect their approach to literature with technology. This essay addresses that gap by showing that poetry is prevalent in contemporary culture due to innovative digitization efforts and the creation of poems unique to digital culture. Using a mixed interpretive approach that combines close reading, media analysis, and recent transliteracies research, a concept originally developed in 2005 by Professor Alan Liu at the University of California at Santa Barbara, this essay traces poetry's journey into its current forms in blogs, video games, and social media platforms. Findings suggest that transliteracy is the defining quality that has enabled younger generations to incorporate poetry in digital platforms, fostering active participation in virtual environments that support collaborative authorship, accessibility, and cross-cultural connection in that process.

Abstract Name: Molecular Changes in the Basolateral Amygdala Following Vagus Nerve Stimulation-Enhanced Extinction of Conditioned Fear

Post-Traumatic Stress Disorder (PTSD) is a psychiatric condition characterized by the persistence of maladaptive fear memories. Symptoms include anxiety, hypervigilance, and functional impairment. Exposure therapy is one of the treatments for PTSD, but dropout rates are high, and half of patients lack optimal responses, therefore the need for alternative treatment methods that accelerate therapeutic effects. Vagus Nerve Stimulation (VNS), an FDA-approved neuromodulatory technique, has been shown to enhance fear extinction in male rats, particularly through plasticity in the infralimbic cortex (IL) to basolateral amygdala (BLA) pathway. However, the molecular mechanisms underlying this effect remain incompletely elucidated. Additionally, little is known about whether VNS has similar effects in female rats, despite their higher prevalence of PTSD. The aim of this initial study is to test auditory fear conditioning (AFC) and extinction in female rats. AFC consisted of administration of a 1-sec 0.4mA footshock to rats during presentation of a 30-sec, 9Khz, 85dB sound. Following AFC training, rats were given a single day of extinction training, where the sound was presented without the footshock. Conditioned fear was measured 24 hours later, and brains were extracted, sectioned on a cryostat, and BLA tissues were punched for downstream proteomic analysis. Our behavioral results showed that VNS failed to enhance extinction in female rats, suggesting sex-differences in neural nodes involved in VNS-accelerated extinction effects. Future work includes assessing the sex-specific molecular signature underlying VNS effects on extinction by conducting an unbiased proteomic analysis of the BLA tissue.

Abstract Name: Optogenetic stimulation of Rho GTPases in MDCK cells

Rho GTPases, such as RhoA and Rac1, control the spatiotemporal organization of the actin cytoskeleton, enabling cell adhesion, force generation, shape changes, and migration that underlie tissue dynamics. Ras homolog family member A (RhoA) in particular plays an important role in actin organization and cell contractility. Optogenetic stimulation of RhoA provides an experimental means of controlling when and where it is activated, enabling mechanobiological studies of force generation in epithelial cells. It was previously shown that optogenetically induced clustering of RhoA can lead to increased RhoA activity. To test this approach in epithelial cells, we transfected Madin Darby Canine Kidney (MDCK) cells with an optogenetic RhoA clustering construct via electroporation and confirmed expression by fluorescence imaging of the associated mCherry tag. RhoA of the expressed construct was observed to be initially diffusely located in the cell. When stimulated using 470 nm light, we found that RhoA began to cluster into oligomers that were visible as supra-micron-scale puncta within 10s of seconds. Phase imaging showed that the MDCK cells maintained their morphology during stimulation over several minutes. This suggests that RhoA activation via clustering was not excessive enough to cause very high contractility and adverse cell morphological changes. Additional testing of the opto-RhoA-mCherry and opto-Rac1-mCherry constructs will evaluate whether direct membrane recruitment of each Rho GTPase induces either contractility or protrusions, respectively. Overall, we have successfully optogenetically clustered RhoA in MDCK using blue light, establishing a platform for spatiotemporally resolved mechanobiology studies that can help understand how epithelial cells generate and transmit force.

Abstract Name: Conditional Degradation of CHC-1 in *C. elegans* Using the Auxin-Inducible Degron System

Clathrin is an essential component of intracellular transport, a process required for proper cell division. When clathrin function is disrupted, uncontrolled cell growth can occur, contributing to cancer progression and neurodegenerative diseases. In the nematode *Caenorhabditis elegans* (*C. elegans*), the clathrin heavy chain protein CHC-1 regulates intracellular vesicle transport during early embryogenesis. However, clathrin has also been observed at the centrosomes and mitotic spindle, and the function of CHC-1 at these locations in *C. elegans* remains unknown. This study aims to determine how CHC-1 degradation affects cell division dynamics in *C. elegans* embryos. To conduct these experiments, we used a strain containing four components: TIR1-Flag (used to recruit AID-tagged proteins for degradation in the presence of auxin), AID-tagged CHC-1 (used to conditionally deplete CHC-1 upon auxin treatment), mNeonGreen-tagged CHC-1 (used to visualize CHC-1 localization and monitor degradation efficiency), and mCherry-tagged tubulin (used to visualize microtubules and mitotic spindle structure). This system enabled conditional degradation of CHC-1 using 2 mM auxin. Ethanol-treated worms served as the control because ethanol was the solvent for auxin. Preliminary results reveal that auxin-treated embryos show reduced mNeonGreen-CHC-1 fluorescence, whereas ethanol-treated embryos display a strong CHC-1 signal. These data confirm successful CHC-1 depletion in the presence of auxin. Variations in early cell division patterns were also observed, suggesting that CHC-1 is required for proper cell-cycle progression. However, worms exposed to 2 mM auxin

grew significantly more slowly than controls, resulting in far fewer gravid worms available for imaging. Because 1-cell embryos constitute a small proportion of total embryos, this growth delay limited the number of embryos available for analysis. To address this limitation, future experiments will include additional auxin-treated plates to ensure adequate embryo yield. Successful completion of this work will reveal new insights into the role of CHC-1 in *C. elegans* cell division.

Abstract Name: Genetic studies of dominant lethal mutations in core histone genes

The nucleosome core particle (NCP) is a universal subunit of eukaryotic genomes, comprised of an octamer of four core histones H2A, H2B, H3, and H4, and ~146 base pairs of DNA. Histones are essential proteins, and their post-translational modifications make up the basis of “epigenetic” (i.e. sequence-independent) regulation of all genomic functions. Histones are exceptionally conserved across all eukaryotes. Further, in all multicellular organisms each core histone isoform is encoded by dozens of near-identical paralogs. Missense mutations in core histone genes occur frequently in many cancers, yet the biological effects of most of those are poorly understood. To refine the true “driver” mutations we reasoned that critical residues in histones must be constrained in healthy population. Interrogating gnomAD 4.1 data encompassing over 800,000 human exomes and whole genomes from diverse healthy subjects – corresponding to ~30 million individual histone alleles – we assembled a saturated map of synonymous and missense variants across all core histone genes. These studies identified only three entirely invariant residues (i.e. ones that tolerate no substitutions), as well as cases where a specific expected missense variant was missing from the population, all suggesting yet-unknown dominant mechanisms of extreme biological significance. As all such mutations have strong dominant effect, we developed a stable, selectable, inducible expression system allowing us to switch the accumulation of the mutant histone on demand, in a time-controlled manner. To investigate whether dominant phenotypes of histone mutants require incorporation into the NCP and genome, we generated a series of double mutants, disrupting the invariant residues together with critical hydrophobic surface required for the histone fold domain “handshake”; effects of such double mutations are currently under investigation by a combination of cell-based and transcriptomic analyses. Together, our studies aim to understand the biochemical and biological role of exceptionally conserved, essential amino acids in core histones.

Abstract Name: A Preliminary Investigation of E-cigarette Usage among Pregnant Patients in Alabama

Rates of electronic cigarette (e-cigarette) use during pregnancy have been increasing over the past decade, raising concerns about the potential effects on perinatal health. Pregnancy-related physiological changes make pregnant women more susceptible to e-cigarettes due to the many flavors provided. The perception of e-cigarettes being less harmful than other tobacco products is another reason that pregnant women may choose to use e-cigarettes during their pregnancy. Physiological and hormonal changes can make pregnant women more vulnerable to nicotine and other toxicants found in e-cigarette aerosols. However, research on the effects of vaping during pregnancy is extremely limited. This study investigates the extent of e-cigarette usage during pregnancy in a cohort of patients at the University of Alabama at Birmingham (UAB) hospital. Participants were recruited from prenatal clinics to complete a smartphone-based survey on tobacco use. The demographic portion of the survey included questions about race, education level, employment status, and residency. The survey then included detailed questions about primary use and secondary exposure to e-cigarettes. To date, 523 participants have taken our survey. Of the total, 422 answered tobacco-related questions. The average age was 29 years. The cohort was predominantly White (48.1%) and Black (40.6%). Of those surveyed, 20 (4.7%) reported exclusive vaping during pregnancy. Vapers were disproportionately White (60%). Self-reported vapers had a significantly lower level of education compared to participants reporting no tobacco use ($p = 0.0012$). Most vapers reported daily use of disposable e-cigarettes with 1–10 puffs per day. Vapers also reported exclusive use of flavored e-liquids and switching from cigarettes to vaping. The current findings highlight the need for future research into vaping during pregnancy. Ongoing analyses will further clarify the effects of vaping on maternal and perinatal health outcomes.

Abstract Name: Dreaming Across the Lifespan: A Content Analysis

This study investigates longitudinal changes in dream content across multiple decades to empirically examine how dreams evolve over time. Dream narratives were recorded by the principal investigator (PI) and are randomly selected to be coded by a trained team of researchers. Dream elements were categorized into six core domains: objects, actions, people, emotions, settings, and complexes. Rigorous coding guidelines were implemented to ensure reliability and consistency in analysis. The study utilizes an autoethnographic approach, where the PI serves as both researcher and participant to enhance narrative depth and reflexivity. Statistical analyses will be conducted to examine variations in dream content between different decades of the PI's life. This paper examines whether significant differences exist between 100 dreams recorded during the principal investigator's twenties and 100 dreams recorded during their thirties, and characterizes the nature of these differences. The continuity hypothesis posits that dreams reflect waking life, and this research adds onto that premise by arguing that transformations in life circumstances correspond to shifts in dream patterns (Erdelyi, 2017). This study is currently ongoing, but the findings aim to advance scholarly discourse on dream analysis and contribute to theoretical frameworks for understanding the evolution of dreams over time.

Abstract Name: Warm Hands, Warm Hearts: Emergency Winter Preparedness

Flagstaff's extreme winter climate places unsheltered individuals at high risk for hypothermia, frostbite, and other preventable cold-related illnesses. These risks have disproportionately affected Native Americans and low-income community members, reflecting persistent health inequities in Northern Arizona. Compounding these disparities, limited shelter capacity and rising living expenses reduce access to adequate winter protection, underscoring the need for emergency winter preparedness as a critical public health priority. This project worked closely with Community Assistance Teams of Flagstaff (CATs), which assist unsheltered residents in Flagstaff and help meet their basic needs, including food and clothing. This intervention aimed to reduce cold-weather health risks by implementing a community-based winter preparedness intervention using 3 activities: (1) collected winter clothing donations, (2) assembled winter preparedness kits containing blankets, thermal wear, and hand warmers, and (3) fundraised \$432.23 To evaluate the intervention's impact, participants completed pre- and post-surveys to assess their perceived preparedness, likelihood of using kit items, and their overall sense of winter preparedness. Program effectiveness was measured by tracking the number of items donated, assembled, and distributed across the intervention period. These assessment strategies provided both quantitative and qualitative insights into the intervention's reach and its influence on participants' preparedness. By addressing immediate cold-weather needs and promoting safer behaviors, this project contributed to ongoing efforts to reduce winter-related health disparities in Flagstaff. Surveys showed that 19 individuals were very likely to use kit items, showing a high perceived utility. Fewer than five individuals reported being unsure whether they would use kit items. Surveys also revealed that 42.9% felt prepared for winter, 28.6% felt moderately prepared, and 28.6% felt unprepared. These findings will inform future health initiatives aimed at protecting vulnerable populations during extreme weather conditions.

Abstract Name: Qualitative Analysis of Tropical Crop Cultivation in Eastern Thailand Caused By the Effects of COVID-19 and Climate Change

Will the future agricultural landscape return to a pre-pandemic state? If yes, how fast? If not, what will be different? The combined impacts of the COVID-19 pandemic and climate change have reshaped Eastern

Thailand's agricultural industry with dramatic implications. Urbanization, which heavily fuels climate change, is also becoming an increasingly noteworthy threat to farmers in areas near megacities. This study examines the dual impacts of climate change and a pandemic on tropical agriculture, and predicts the extent to which land cover will urbanize by the year 2030. As part of a mixed-methods convergent-parallel approach, the qualitative portion gathered information from stakeholders with acute insight into the factors driving this dramatic transition away from pre-pandemic agricultural practices. These were done through interviews with farmers and key stakeholders in the agricultural sector. Concurrently, these findings were used to inform predictive models for the quantitative portion, which reveal futures of increased urbanization into forests and farmland based on current socioeconomic and environmental trajectories. Many farmers have invested in agricultural technology to adapt to climate change and labor shortages, especially with the increased market price of exported fruits like durian. Water availability has been one of the most prevalent challenges for farmers as floods and droughts increasingly become unpredictable. These findings make a return to the pre-pandemic state unlikely.

Abstract Name: Investigating Arc Expression in the Hippocampus Across the Sleep-Wake Cycle

The Arc gene is rapidly activated during learning and is essential for the structural changes that underlie the consolidation (stabilization) of long-term memories—most notably in the hippocampal region of the brain. Although memory consolidation may occur exclusively during sleep, and Arc is required for consolidation, available data show conflicting evidence as to whether sleep impacts Arc expression. Our goal is to quantify Arc expression in the hippocampus region of the brain in relation to sleep versus wake. We confirmed rat sleep/wake state by using video recording software for the last three hours prior to brain collection. We examined four different time points in the sleep-wake cycle: 3 hours/8 hours into the wake period and 3 hours/8 hours into the sleep period. We performed immunohistochemistry to visualize Arc positive cells in the hippocampus. The hippocampal area was measured using ImageJ software, cells were manually counted using microscopy, tissue thickness was calculated using confocal microscopy, and these values were used to calculate cell density. Video recordings confirmed that rats were predominantly sleeping during the light period and awake during the dark periods. Preliminary data were analyzed using a one-way ANOVA, which revealed that there was no statistical significance in cell density between the four sleep/wake timepoints ($F(3, 38) = 0.8256$, $p = 0.4880$). Nominal differences show that Arc-positive cell density is higher during wake. The data provides important insight into the molecular mechanisms underlying sleep-mediated memory formation and begins to reconcile the conflicting findings on Arc expression during wake and sleep. Future studies should incorporate a behavioral component in order to examine Arc expression during post-learning sleep; potentially providing greater insight in the temporal dynamics of Arc expression during memory consolidation.

Abstract Name: Body Horror, Cronenberg, and Society

Body horror is an incredibly influential subgenre within the horror film space. This cinematic subgenre is defined by its depiction of unnatural and grotesque transformations of the human body. Body horror films are filled with fascinating and meaningful explorations of how humans relate to society, to one another, and to their bodies. David Cronenberg is arguably the most influential director to work within this subgenre. Cronenberg has directed 23 feature films, including *The Brood* (1979), *Videodrome* (1983), *The Fly* (1986), *Dead Ringers* (1987), *Crash* (1996), and *Crimes of the Future* (2022). With my research, I seek to answer the question of what Cronenberg's work, and body horror cinema in general, can tell us about the things we fear happening to our bodies, and what that says about society at large. My methodology involves reading books, interviews, and articles about his work, as well as watching his entire filmography. I am also watching other body horror films released across multiple decades and around the world as a point of comparison. In my research, I utilize an auteurist perspective to explore recurring characters, themes, and cinematic markers in Cronenberg's work. Specifically, I focus on Cronenberg's frequent depiction of scientists, physical transformations, technological overreach, and fluid sexualities. These elements combine to create a deeply impactful psychological experience for the audience. I conclude that by utilizing imagery that other subgenres, including those in the horror space, avoid, body horror films are uniquely able to reflect societal anxieties over our relationships with ourselves, technology, and our obsessive desire to constantly change our bodies and minds.

Abstract Name: Genomic Characterization of a Novel *Pseudophaeobacter* Strain Isolated From Antarctic Ice Cores

We present the first novel strain of *Pseudophaeobacter* cultured from the Antarctic region and highlight differences between strains found in the U.S., China, and Western Europe. Isolates were cultured from long-term enrichment using seawater ice cores from the McMurdo Sound station. Specifically, two samples were enriched to culture bacterial isolates that can degrade complex sugars as part of their metabolic process. The samples underwent serial dilutions, plating, and streaking to obtain a pure culture. Taxonomic classification based on 16S rRNA gene comparison and phylogenomics identified the isolate as *Pseudophaeobacter* sp. Growth rate analysis indicates that both isolates were unable to utilize the algal polysaccharides and relied on public goods produced by other microbes in the communities. Genomic DNA was obtained, sequenced using a shotgun approach, and analyzed using an established HU genome assembly pipeline (FASTQC, Trimmomatic, SPAdes, QUAST, and PROKKA). A total of 4,275 protein-coding genes and 54 tRNAs were predicted for the 01NG25A isolate, while 4,376 protein-coding genes and 54 tRNAs were predicted for the 01RR25 isolate. Compared to reference genomes, both isolates clustered together, and singleton genes were associated with responses to cold (thermal shock, protein misfolding, and transmembrane proteins) and oxidative stress (nucleic acid protection, modulators of detoxification, and integrity of chaperone proteins). Phylogenomics using 95 unique single-copy core genes placed the isolates closest to *Pseudophaeobacter arcticus* with an ANI of 89–92% across the full genome. Additionally, the ANI of the aligned regions exhibited >98% identity. These results suggest that the isolates are novel strains within the genus *Pseudophaeobacter arcticus*, cultured from opposite poles (Arctic and Antarctic).

Abstract Name: The Analysis of Video Games as Text: How The Elder Scrolls III: Morrowind Uses Focalization Under a Structuralist and Meta-narrative Analysis.

How are structuralist elements of narrative recontextualized and a player-driven meta-narrative revealed under the interactivity of a video game like Morrowind? This project draws upon structuralist and meta-narrative literary theories to analyze the video game, The Elder Scrolls III: Morrowind, exploring how critical literary theories unravel the non-traditional medium of video game storytelling and how players' interactive role enhances narrative elements. Previous research has investigated video games as literature, role-playing opportunities in interactive storytelling, and the general application of literary theory in critical analysis. This project addresses the gap in existing research by exploring how literary analysis explains gameplay mechanics—like role-playing choices—that redefine narrative elements and expand the literary storytelling in and beyond video games. In Morrowind, players control the supposed reincarnation of a religious figure in a medieval fantasy. Players navigate political tensions and different interpretations of religious history through

characters' differing perspectives, dictating their own truth through role-playing choices. Using structuralist and meta-narrative criticisms, the research explores interactivity as narrativity, unreliable narration through focalization points and rhetorical relative truths, and communal discussion of canonicity in subjective truths. Structuralist findings indicate that traditional storytelling elements are recontextualized and overlapped due to interactivity implicit in video games, thereby redefining how audiences engage with progression/digression, identity-making, and narration; as all narration takes place in-text, objectivity is obscured through focalized, subjective, lived truths. Meta-narrative findings indicate that players use a combination of in-text lived truths, role-playing choices, and gameplay systems—like character creation—to develop their own lived truth, replicating the discourse of canonicity, first seen in-game, with other players in the real world to establish an objective truth. These conclusions contribute to ongoing applications of literary theory in the critical analysis of video games and how non-traditional storytelling mediums subvert narrative elements due to audience interaction.

Abstract Name: Tradition Reconsidered: Fikos and Contemporary Byzantine Painting

When considering Byzantine art, it's tempting to associate it with the past, but doing so obscures its vibrant relevance today. Artists around the world still draw from its techniques, most notably the Greek artist Fikos Antonios (b. 1987), who coined the term Contemporary Byzantine. This research examines how Fikos sustains and reimagines the Byzantine visual tradition within a contemporary cultural context. Though often viewed as a relic of the past, tied to sacred subjects, this study argues that Byzantine art's visual system, rooted in rhythm, line, and color relationships, remains active and adaptable within Contemporary Byzantine art. Through a visual analysis of his mural *Peace* (2024), located along the UN buffer zone in Nicosia, Cyprus, this study demonstrates how Fikos revives Byzantine structures while expanding their role beyond ecclesiastical spaces. Integrating stylistic analysis with cultural studies and postcolonial theory, this paper examines *Peace* within its socio-historical context. The mural's composition, relational perspective, and chromatic rhythm sustain the internal logic of Byzantine image-making, yet its public placement and explicitly political subject recast this visual language as a vehicle for collective memory and cultural resilience in a post-occupation landscape. The writings of Photis Kontoglou and George Kordis help establish a coherent formal lineage, while Homi K. Bhabha's *The Location of Culture* (1994) and Edward Said's *Culture and Imperialism* (1993) situate the work and Contemporary Byzantine art within wider discourses of identity, hybridity, and cultural continuity. Through this discussion, I demonstrate how Byzantine art operates as a "living tradition," negotiating between preservation and innovation, sacred inheritance and modern identity. By bridging stylistic analysis with cultural and postcolonial theory, this study contributes to the emerging scholarship on Contemporary Byzantine art and reconsiders how historical visual languages endure, transform, and communicate in today's globalized public space.

Abstract Name: Shift Work History Moderates Relationships Between Measures of Sleep Health and Blood-Based Synuclein Biomarkers

Introduction: Night shift work is associated with poor sleep both during work exposure and in retirement. Both poor sleep and night shift work are also associated with dementia. Characterizing the health risks of shift work is key to forming health recommendations surrounding this growing line of employment. Few studies examine multidimensional, habitual sleep patterns in individuals previously exposed to shift work. Newly identified biomarkers of neurodegeneration offer opportunities to identify disease processes before they manifest clinically. This study examined relationships between sleep health and neurodegenerative biomarkers in retired day workers (RDW) and retired night shift workers (RNSW). Methods: Participants (mean age=67.7) were 33 RDW and 25 RNSW. Multidimensional sleep health (MDSH) was quantified using actigraphy-derived sleep efficiency, timing, duration, and regularity, a diary measure of sleep satisfaction, and an Epworth Sleepiness Scale (ESS) score to measure daytime alertness. A panel of neurodegenerative biomarkers were quantified by Nucleic Acid Linked Immuno-Sandwich Assay (NULISA). Principal component analysis of biomarkers revealed 8 components including degenerative and protective characteristics for various neurodegenerative patterns. Interaction models tested associations of MDSH with these biomarker components in RDW and RNSW. Results: Shift work history moderates the relationship between sleep timing and protective synuclein biomarkers, with later-sleeping RNSW exhibiting higher protective synuclein biomarker levels (interaction coefficient=0.037, FDR-corrected $p=0.028$). Shift work history also moderates a quadratic relationship between sleep duration and biomarkers of synuclein-related degeneration, with RNSW exhibiting lower degenerative synuclein biomarker levels at short and long sleep durations (interaction coefficient=-0.00041, FDR-corrected $p=0.049$). Conclusion: At extreme values of sleep duration and late sleep timing, RNSW are better protected against synaptic and synuclein dysfunction than RDW. RNSW are more likely to have abnormal sleep patterns during their working years, which may have allowed for greater resilience to late sleep timing and extreme sleep duration in retirement.

Abstract Name: Characterizing the Heterogenous Mechanical Properties of the Patellar Tendon

Ligaments and tendons are composed of two distinct heterogenous materials: fascicles and the interfascicular matrix (IFM). These connective tissues are viewed as a single transversely isotropic material to make computations easier. However, recent work suggests that separating these two materials is necessary to model tissue failure. While previous research has explored fascicular mechanical properties, IFM mechanical properties have not yet been characterized. The goal of this study is to characterize the mechanical properties of the IFM and fascicles using heterogeneous patellar tendon samples. 24–36 hours post mortem, a sheep patellar tendon was resected. After dissection, 3 mm samples were obtained, dyed to differentiate fascicular vs IFM regions, speckled with white and black paint from a 25 psi airbrush, and pulled at 1%/s using an universal mechanical testing system. Images were acquired at 1 Hz for digital image correlation (DIC).

Through DIC analysis, the displacement and strains of the samples were obtained. This study found that strain hotspots occur in the IFM, with failure often initiating in the IFM. These findings demonstrate that failure occurs locally within a patellar tendon sample, improving the ability to model failure of whole ligament and tendon specimens.

Abstract Name: Polymer-modified Copper Based Catalysts for the Conversion of Carbon Dioxide

Carbon Dioxide (CO₂) is abundant in our atmosphere, and its conversion to value-added chemicals using renewable electricity is an active area of investigation. Previous research has shown that copper-based catalysts can produce a wide range of valuable chemicals and fuels such as methane through the electrochemical reduction of CO₂. Recently, we have demonstrated the synthesis of an organic polymer called polypyrrole (pPy) and its use to support the primary copper catalyst for this conversion. These polymers are an intriguing topic of research because they are plastic-like materials that, but unlike most plastics, conduct electricity and can be modified to have different functional properties through traditional organic synthesis. These nitrogen-containing polymers are hypothesized to have a co-catalytic effect that enhances CO₂ conversion due to the coordination chemistry between the nitrogen atoms and the CO₂ substrate, which help stabilize the reaction intermediates. Herein, we report our findings on the electro-deposition of pPy films of varying thickness (100 nm – several microns) on sputter coated copper substrates and their use as catalysts for the conversion of CO₂ using a flow-type cell at neutral pH. Catalysts are characterized by using various tools such as X-ray diffraction (XRD) and scanning electron microscopy (SEM) to understand changes to their crystal structure and morphology. We also use X-ray photo electron spectroscopy (XPS) to understand changes in the chemical makeup of the surface before and after electrocatalytic testing. Finally, we will present preliminary findings on the synthesis of co-polymers containing various nitrogen containing chemical moieties that promise to demonstrate enhanced catalytic activity.

Abstract Name: Enhancing Digital Forensic Investigations: A Study on the Accuracy of Magnet.AI

Magnet.AI is a feature of Magnet Axiom's digital forensics platform that automatically classifies digital evidence based on user-specified criteria. While designed for efficiency, questions remain about its accuracy and reliability under real-world conditions. Located under the AXIOM Process "Processing Details" section, two options for Magnet.AI analysis are available: "Analyze pictures with Magnet.AI" and "Analyze chats with Magnet.AI." Multiple criteria exist for each, such as "Animals" and "Human Faces" for pictures, and "Grooming/luring" for chats. This study aims to evaluate Magnet.AI's performance through two photo criteria, "weapons" and "drugs", and test five key metrics: False Positive Rate, False Negative Rate,

Precision, Recall, and Accuracy Rate. A controlled dataset of 60 verified images of weapons and drugs, as well as 1500 out-of-criteria photo files, will be analyzed to measure these metrics. Each file will be reviewed for content, format, and type. The data will be processed through AXIOM Process and reviewed in AXIOM Examine. Results will be documented in an Excel spreadsheet, where analysis will be performed. By validating Magnet.AI's functionality for identifying the "weapons" and "drugs" categories, this study aims to determine whether the feature provides dependable support for digital forensics examiners or if its inconsistencies risk compromising evidentiary integrity.

Abstract Name: Designing a Modern Church to Contribute to the Community and Create a Welcoming Environment

Churches often carry a negative reputation shaped by past experiences, such as feelings of rejection, unwelcoming interactions, or environments that appear intimidating due to their design or layout. The core message of Jesus Christ is love and welcome for all, and churches that genuinely embody this by being open to people of any background can greatly reduce these negative perceptions. In response to these challenges, this project aims to design a modern church with community-centered spaces that reshape how people perceive churches. Data was gathered through in-person group interviews with young adult members of a local church in Oklahoma City to explore their experiences and their needs and preferences in a church setting. The proposed church emphasizes community service by offering public spaces accessible throughout the week to provide comfort, connection, and support for real needs identified through local research, including rising poverty rates, lower test scores, and increasing technology-related anxiety among Gen Alpha. To address these needs, the design includes a donation center, children's playground, student study area, and gym/basketball court, along with a welcoming lobby, a 600-seat worship room, and a large café and event space. These areas incorporate natural light and connections to the outdoors to support well-being, while promoting a culturally diverse and welcoming environment. These thoughtful, community-focused design features help transform the church environment, removing barriers and creating a home-like place where everyone feels welcomed and supported.

Abstract Name: Queering Liberatory Movements: Willful Cross-Solidarity Action in the Face of Fascism and Domination

This research study examines the activist organizing that communities of color, queer and transgender communities, and disabled communities are engaged in to resist the impact of fascism in our current political moment. Our team focuses on how the survival tactics, ancestral knowledge, and cross-solidarity commitment of organizers counter fascism's hate, divisiveness, and domination. We argue that the only way

to create sustainable change is to create beloved communities rooted in what Black feminist bell hooks names a “love ethic.” “Beloved community is formed not by the eradication of difference but by its affirmation, by each of us claiming the identities and cultural legacies that shape who we are and how we live in the world.” We know that fascism’s foundation is built on hate and that it is a porous and exploitable system. Through an intersectional and interdependent network of cross-solidarity movement organizers, we center the work that is currently being done in Southern California to dismantle and deter fascism nationwide. What does our future hold if our movements refuse to leave anyone behind?

Abstract Name: Beauty Standards in Social Media: Differential Impacts on Young Women's Self-Perception

Instagram and TikTok are where most young women see beauty standards every day. While these apps let people be creative and connect with others, they also show heavily edited and perfect-looking images that can change how young women feel about themselves. Recent research shows that even "body positive" videos on TikTok usually feature thin, white women (Harriger et al., 2023), and beauty filters make people look lighter-skinned and more European (Riccio et al., 2024). But most studies look at "social media" as one thing and mostly study white women, so we're missing important differences between apps and between different racial and ethnic groups. This paper reviews existing research on how Instagram and TikTok affect self-perception in young women from different backgrounds. Using social comparison theory, objectification theory, and recent studies (Bonfanti et al., 2025), I found four major gaps in what we know: (1) no studies directly compare Instagram and TikTok even though they work differently—Instagram shows perfect still photos while TikTok has constantly changing beauty trends, (2) most research focuses on white women and doesn't look closely at Asian, Latina, Black, and Native American women separately, (3) research focuses on negative effects and rarely studies what protects women from harm, like strong connection to their cultural identity, and (4) most studies collect data at just one moment rather than following the same women over time, so we cannot prove social media actually causes these problems versus just being connected to them. Based on these gaps, I propose a new framework showing how different apps and different cultures combine to affect young women differently. This framework suggests that strong ethnic identity helps protect women of color and can guide better, culture-specific ways to help young women stay healthy online.

Abstract Name: Genetic and Phenotypic Diversity of Novel Oomycete Species Isolated from Freshwater Streams in Lancaster County, PA

Oomycetes are fungal-like microbial eukaryotes that are ubiquitous in nature. The group contains many well known plant pathogens that can cause significant damage in agricultural systems; for example, *Phytophthora infestans*, the causal agent of potato late blight, is infamous for driving the 19th century Irish potato famine.

Less is known about the diversity of aquatic oomycetes and their ecological role as potential pathogens. Some oomycete genera, including *Saprolegnia*, *Aphanomyces*, and *Pythium*, contain aquatic species that are known to infect invertebrate and vertebrate animals, including mammals, even when closely related species are soilborne plant pathogens or saprotrophs. In this study, we describe several novel aquatic lineages that have been isolated by our laboratory through repeated stream sampling in Lancaster County, Pennsylvania. Four of these lineages likely represent new species, and two others are possible hybrid lineages of unknown origin. Genetic diversity was assessed through phylogenetic analysis of both nuclear (ITS, Beta-Tubulin) and mitochondrial (COI, COII, rps10) loci. Phenotypic traits such as growth pattern and rate on multiple agar substrates, as well as optimal growth temperature, were measured for a subset of isolates from each novel lineage. Some isolates from two of the potential new species showed high thermotolerance up to 40°C, suggesting the evolutionary potential for mammalian pathogenesis. The basis for high thermotolerance in these novel species is unclear; the temperatures survived by isolates far exceeds that of the waterways they were collected from. Interestingly, there was no genetic variation among isolates that differed in their thermotolerance. Next we will examine differences in expression levels for several genes, including heat shock proteins and potential virulence factors, among isolates grown at different temperatures. These results will contribute to our broader understanding of the biology of emerging pathogens, and emphasize the importance of routine biodiversity surveys in our local waterways.

Abstract Name: The Imperialists of the Peloponnesian War

The Sicilian Expedition is known as the foremost strategic failure that led to Athens' downfall in the Peloponnesian War. While this undoubtedly played a role in the fall of Athens, it is not the sole perpetrator. A revisiting of the Persian Empire, the Delian League, and the Peloponnesian League can show how their political, cultural, and social norms affected the outcome of the Peloponnesian War. By the 6th century BCE, the Persian Empire had conquered an immense amount of land, spanning multiple cultural, national, and ethnic groups across the Middle East. During their rise, Sparta began to accrue several allies through a series of oligarchy-based treaties known as the Peloponnesian League. Athens, fresh off the victory against the great Persian Empire, formed a fresh democracy under the Delian League in 479. These governing systems may not seem comparable at first, but when one takes a step back to view their political patterns, they can realize the similarity between the three. By the end of the Peloponnesian War, however, both Sparta and Athens had lost immense amounts of resources. With Athens on the ropes, Sparta neck deep in corruption, and Persia scheming in between, these three figure heads of the late 5th century BCE would collide in a chaotic race for power. Through a dive into the cultural and political natures of Athens, Sparta, and Persia, this essay will add to the academic discussion of the Peloponnesian War by discussing how Sparta, Athens, and Persia, while under the guise of different governments, are all imperialistic in nature. Although they have different means, their end goals are the same; conquer.

Abstract Name: RRBS Profiling for Identification of Obesity-Induced Liver Methylation Changes of Metabolic Regulation in *Danio rerio*

DNA methylation is an epigenetic modification that plays a crucial role in regulating gene expression and maintaining genomic stability. Cytosine residues at CpG sites are primary targets of methylation, and aberrant patterns at these loci have been closely linked to obesity and subsequent metabolic dysfunction in humans. The model organism, *Danio rerio* (zebrafish), was used to evaluate obesity-associated alteration of liver methylation patterns. To analyze discrepancies between control and obese zebrafish, reduced representation bisulfite sequencing (RRBS) was performed. Raw sequences were trimmed through Trim Galore, aligned to the zebrafish reference genome using Bismark. SeqMonk and methylKit in R software analyzed the sequences in preparation for the differential methylation analysis performed by Gene Ontology (GO) to characterize the functional impact of the methylation alterations. Initial findings indicate that obesity induces methylation alterations in pathways central to metabolic homeostasis. Methylation changes were found to impact genes involved in lipid metabolism, inflammatory signaling, and glucose regulation. These results suggest that obesity-driven epigenetic modifications may predispose individuals to comorbidities such as NAFLD, type II diabetes mellitus, and hypertension. This study builds a foundation for future work that integrates methylation and gene expression analyses for obesity epigenetics and advances understanding of the molecular pathways that link obesity with chronic metabolic disease.

Abstract Name: Stephen King's *The Long Walk* for the 10th Grade Classroom

Authors are inspired by past and current fears of society, using their craft to expose the latent fears of humanity. Dystopian fiction is the manifestation of these fears, pulling hypotheticals based in reality to craft worlds held in the iron grip of a malevolent power. Stephen King's *The Long Walk* explores the grotesque union of game-show motifs and slaughter as characters compete for a grand prize, and the losers are murdered. Scholars have discussed the potential for studying King and dystopian novels in the classroom, yet school districts often overlook dystopian novels in their approved literature. This project seeks to fill the gap in high school literature curriculum by formulating a unit plan for teaching *The Long Walk* for the 10th-grade English language arts classroom. Students will be responsible for researching the context *The Long Walk* was written to explore how the dystopian fiction genre reflects reality. Students will also research banned books to question why many of King's novels are banned, and consider the validity of censorship in public schools. Following the Maryland College and Career Ready Standards, engaging project-based lessons and activities have been designed to challenge students with a thorough study of society and literature. Students will be proficient in research and close reading, using these skills to reflect on history, dystopian literature, and politics, to grow as academics.

Abstract Name: *For the Love of Fate: Observing the Possibilities of Friedrich Nietzsche's Concept of Amor*

Fati as a Tool for Collective National Memory

Amor fati is a concept associated with philosopher Friedrich Nietzsche that embraces the active loving of one's fate, including all the hardships endured—as without them, one would not be as they are. While this concept is often discussed at the individual level, the core idea is that this collection version of amor fati can be a guiding principle for reconciliation and progress after mass violence, as it focuses on transforming guilt into action and acknowledgement into improvement. Using an upside-triangle method starting with the individual level, I move upward describing what the uptake of collective amor fati would look like at a small collective, proximal community, population community and identity-based collective level along with the three conditions necessary for amor fati to be established. I also describe markers of successful adoption of amor fati as well as address common political problems that arise when working with larger communities. For my main example, I use Germany's post-Holocaust national memory to explain how collective amor fati might be conceptualized, and more broadly propose some of the related lessons that other post-atrocity states can draw from it. I am providing my own theory of collective amor fati, offering a realistic glimpse of what application to different population levels looks like and what successful outcomes might be. Applying amor fati to the collective sphere can change how history is seen and valued, without leading to the evasion of responsibility. It also serves to alter a nation's relationship with their past for the better while actively envisioning the construction of a healthier and hopeful future. Collective amor fati aims to benefit entire populations and serves as a realistic option for those who are dedicated to self betterment and supporting collective flourishing.

Abstract Name: Sexual Liberation and Exploration through Erotica or “Smut”: The Importance of Subversive Literature in a Suppressive America

In a country that censors and suppresses information that it deems inappropriate or obscene, sexual education often receives the fate of ignorance or shame. This is especially seen in women's health and knowledge surrounding sex and their bodies. However, the rise of erotic novels or more colloquially known, “smut” allows women to freely read and inform themselves of sex and intimacy. From one of the first erotic novels *Fanny Hill: Memoirs of a Women of Pleasure* by John Cleland to *Fear of Flying* by Erica Jong, and every romance novel in between, the theme of erotica as liberation for women has been a constant trend. Even as shame trickles back in for many female readers, the desire to know more about sex, pleasure, and relationships lead women back to the romance section. This paper examines the role of erotica in literature and its significance to women, especially considering the largely female audience of romance novels containing erotica. The research methodology used in this research paper is textual analysis and scholarship surrounding the ideas represented in the novels. Through close-reading analysis of *Fanny Hill* and *Fear of Flying*, and the theories regarding female eroticism offered by literary theorist Susan Rubin Suleiman in her novel *Subversive Intent: Gender, Politics, and the Avant-Garde*, this research paper will analyze the importance of erotica and smut in sexual exploration and liberation in a suppressive society.

Abstract Name: Visual Rhetorics of Black Power: Hair, Gender, and Ideology in 1970s Blaxploitation Cinema

“You’re a disgrace to everything the Black fists stand for.” – Cleopatra Jones (1973) For Black Americans, hair has never been just a style; it’s a statement, a symbol, and a battleground. The 1970s Blaxploitation era sharpened this tension: afros defied Eurocentric beauty standards as crowns of Black Power, while wigs and straightened hair became survival tools in a white-dominated industry. Films like *Shaft* (1971) and *Coffy* (1973) weaponized these choices, turning hairstyles into cinematic code for power, rebellion, and assimilation. This project decodes how the decade’s 10 highest-grossing Blaxploitation films used hair as visual rhetoric. Through close analysis of *Super Fly* (1972), *Cleopatra Jones* (1973), and others, I reveal: Afros radicalized protagonists (e.g., Foxy Brown’s halo-like ‘fro), while straightened styles villainized antagonists (e.g., *Super Fly*’s Priest’s conk). Gender split the symbolism: Women’s hair balanced respectability politics (straightened bobs) with tactical subversion (wigs as disguise), while men’s styles pit bald individualism (Truck Turner) against Afro solidarity (crowd scenes). Screen time hierarchy: Leads’ evolving hairstyles marked agency (*Coffy*’s wig-to-Afro arc), while background characters’ static Afros echoed collective struggle. Drawing on critical race theory and film semiotics, I argue that Blaxploitation’s hair politics reinforced and disrupted Hollywood’s racial narratives. The afro wasn’t just a style, it was a frame-by-frame revolution.

Abstract Name: Nutrition incentive program participation trends and economic contributions of a SNAP farmers market match program

Food insecurity and limited access to fruit and vegetables (FV) remain significant challenges for many low-income households. Although the Supplemental Nutrition Assistance Program (SNAP) improves food access, cost barriers continue to limit FV consumption, and SNAP households shop at farmers’ markets at lower rates than higher-income shoppers. The Eau Claire Downtown Farmers Market operates a nutrition incentive program, Market Match, that provides additional dollars for FV purchases for SNAP households. We analyzed eight years of linked administrative data (2018–2025) to describe long-term participation patterns and the economic contributions of Market Match to the local food system. The dataset includes 2,457 unique households, enabling the assessment of multi-year engagement both before and after the COVID-19 pandemic. Annual participation, seasonal return patterns, and vendor-level SNAP redemption data were analyzed using descriptive statistics and year-over-year comparisons to estimate economic impacts. More than one-third of participating households returned for multiple years, and over 100 households used the program for at least three seasons, indicating sustained interest and consistent program utilization. In 2025, SNAP shoppers spent \$29,082 at the market, supporting a range of small-scale producers. Using a conservative farmers-market economic multiplier of 1.6, this spending likely generated more than \$46,500 in total local economic activity. These findings highlight the essential role of nutrition incentives in increasing farmers’ market access for low-income shoppers while also strengthening Wisconsin’s local food economy. By documenting multi-year participation trends and economic outcomes, this case study evaluation provides evidence to inform the design of a statewide nutrition incentive model that can improve both food security and agricultural viability.

Abstract Name: Molecular Dynamics Study of Electrothermal Response of Classical Water Models Under an Electric Field

Understanding water's electrical and thermal response under an electric field is crucial for advancing technologies in energy storage, desalination, and electrochemical systems. This study investigates the electro-thermal behavior of non-polarizable water models subjected to varying strong electric field conditions. Although polarizable water models exist, non-polarizable water models remain widely used due to lower computational cost. However, their accuracy under strong electric fields is less understood. Molecular dynamics simulations were performed using 3-site and 4-site water models: TIP4P, TIP4P/2005, TIP4P/ε, TIP4P/XAIE, and SPC/E. The water models were simulated at 298 K with an electric field ranging from 0.0 to 0.3 volts per angstrom (V/Å). Dielectric constant was calculated and compared to experimental data and to the theoretical Kirkwood-Booth equation for dielectric constants at high electric fields. Thermal conductivity and self-diffusion coefficient were calculated and compared with experimental values to assess the accuracy of all five models. Results show that the dielectric constant is modeled more accurately with TIP4P/XAIE and TIP4P/ε, although they are more computationally intensive than TIP4P/2005, which offers lower accuracy. TIP4P/XAIE is the better choice and aligns the closest to the theoretical Kirkwood-Booth equation. Thermal conductivity is best represented with TIP4P; however, all non-polarizable water models yield thermal conductivity values with errors of up to 50 percent. The self-diffusion coefficient is captured accurately with TIP4P/XAIE and TIP4P/ε while TIP4P/2005 provides a less computationally intensive alternative. This demonstrates that while non-polarizable water models capture the dielectric constant and self-diffusion coefficient correctly, non-polarizable models tend to overestimate thermal conductivity, causing significant deviations from experimental observations. These findings advance understanding of the appropriate use of water models and water's electro-thermal behavior that can guide the selection of water models for large-scale simulations, supporting the design of next-generation batteries, capacitors, and water purification devices.

Abstract Name: Direct Simulation Monte Carlo Analysis of Rarefaction Effects during Chemical Vapor Infiltration

Nuclear reactors, automotive engineering, aerospace, and industrial furnaces are applications that require materials that can withstand extreme thermal and chemical environments. This is because the material must maintain structural integrity and performance while resisting degradation. Silicon Carbide (SiC) has these properties, but the low fracture toughness limits its usage. This has led to the development of high-purity, fiber-reinforced SiC matrix composites produced by Chemical Vapor Infiltration (CVI). This study examines the impact of rarefaction, a decrease in gas density, on the deposition rate of SiC. Understanding this relationship is crucial. Rarefaction influences the behavior of particles during the deposition process, impacting the velocity, temperature, deposition rate, and coating quality. CVI works effectively in a rarefied

regime because the lower pressure used allows for better control of the gas flow and reaction rates. To analyze CVI's deposition rate, simulations were performed in Direct Simulation Monte Carlo (DSMC). The simulations were conducted for a range of Knudsen numbers -the ratio of mean free path to a characteristic length- (0.1 to 10), and the continuum model that is based on the Navier-Stokes equations start to break down. Traditional computational fluid dynamics (CFD) software cannot capture the non-equilibrium caused by rarefaction, while DSMC can. DSMC is a stochastic particle-based numerical method used to simulate gas flow at the molecular level in non-equilibrium gas dynamics based on the Boltzmann equation, which can accurately capture the effects on rarefied flow on deposition rate. Simulations were done under Isothermal Forced Flow (IF-CVI) as traditional CVI has long processing times. Preliminary results show that as the Knudsen number increases, the deposition rate decreases along the channel length. These findings demonstrate the influence of rarefaction on the surface reactions that occur on the channel surface, which provides valuable insight to optimize the CVI process and coating efficiency.

Abstract Name: Numerical Investigation of Silicon Carbide Deposition Kinetics under Varying Process Conditions in a Plug Flow Reactor

Many of today's engineering applications—such as nuclear reactors, automotive systems, and furnaces—require materials that can withstand high-temperature environments. Silicon Carbide (SiC) is one such material with an excellent array of properties like high strength, thermal stability, and chemical resistance. However, it has a relatively low toughness, which is the motivating factor in the interest of high purity and high-quality fiber-reinforced matrix composites. This study investigates the effects of varying the operating conditions on the heterogeneous surface chemistry, the amount of SiC deposited, and the production of intermediate species. Understanding the effects of operating conditions is pivotal to optimizing the deposition of SiC, which enables optimized manufacturing and broader accessibility of advanced materials. To address these challenges, complex chemical kinetics involving SiC deposition were modeled using the open-source software Cantera integrated with Python. The simulations employed a validated chemical mechanism file sourced from published literature and experimental data. A Plug Flow Reactor model was selected to efficiently capture both rapid gas-phase and heterogeneous surface reactions while minimizing computational costs compared to full Computational Fluid Dynamics or Direct Simulation Monte Carlo methods. This framework enables extensive parametric sweeps to systematically investigate how operating conditions influence SiC deposition. Results have shown that the deposition of SiC increases significantly with an increase in reactor temperature and residence time, while increasing then plateauing with an increase of the reactor pressure. The intermediates produced during the deposition reactions of SiC such as hydrogen chloride, methane, and other silicon bearing compounds also follow this pattern. Tracking these species is important as for they directly impact the deposition and quality of SiC. These results are important for advancing the materials used in today's engineering applications.

Abstract Name: Secularism and French minority women: how women's exclusion from sports affects French people's perception of a minority?

This project examines how secularism in France shapes the experiences of minority women in sports and how their exclusion from athletic spaces affects broader social attitudes. The central research question asks: Secularism and French minority women: how women's exclusion from sports affects French people's perception of a minority? This study builds on existing scholarship on secularism, gender norms, and social integration in France, highlighting how minority women's visibility, or lack of, has become a key point of cultural and political debate. Using a mixed-methods approach, the project includes a review of current literature on *laïcité* (secularism), gender, and sport, as well as an analysis of previous surveys and reports on minority women's participation and public perceptions surrounding them. The research focuses on four interconnected themes: absence from mainstream sports culture, gender-specific discrimination, nationalist stereotypes, and religious stereotypes. Early observations suggest that exclusion from sports restricts opportunities for minority women while reinforcing misconceptions and biases among the wider French population. These patterns not only shape broader public discussion but also inform policies and practices that further marginalize these communities. The anticipated outcomes will help illustrate how expanding access to sports may counter dominant stereotypes, strengthen social cohesion, and promote more equitable opportunities. Overall, this project aims to contribute to ongoing conversations about gender, religion, and belonging in contemporary France by demonstrating how apparently small barriers in sports participation reflect much larger social dynamics.

Abstract Name: Ferdinand Hodler versus Symbolism: Fairies, Muses, and Femme Fatales

Nineteenth-century Symbolist artists frequently portrayed women through restrictive archetypes, such as the Bathing Venus, the pious maiden, or the seductive femme fatale, to reinforce contemporary beliefs that moral decline was embodied in the female figure. This paper examines how Swiss Symbolist painter Ferdinand Hodler diverged from these dominant conventions and constructed an alternative visual language for representing women. Through close visual analysis of two major works, *Day* (1899–1900) and *Truth II* (1903), this study demonstrates that Hodler rejected traditional tropes in favor of depicting women as active agents and symbols of spiritual, social, and moral progression. In *Day*, Hodler's figures do not invite a voyeuristic gaze; instead, they occupy their environment with autonomy, refusing the passive associations typically assigned to femininity. In *Truth II*, the female nude becomes an emblem of clarity, vitality, and liberation rather than an object of male desire. This research further argues that Hodler's geographic and philosophical distance from Parisian Symbolism shaped his distinct approach. While French Symbolists pursued metaphysical ideals, Hodler's self-developed doctrine of Parallelism sought universal truth grounded in the physical world, leading him to formulate imagery unburdened by the gendered narratives of his contemporaries. Ultimately, this study positions Hodler's work as a compelling countercurrent within Symbolist art, illustrating that mainstream artistic thought does not inherently represent the most insightful or progressive perspectives.

Abstract Name: Existential Meaning, Resilience, and Psychological Well-being in University Students

Psychological well-being is a multidimensional construct encompassing autonomy, personal growth, and a sense of purpose in life. It is increasingly challenged among college students through constant academic pressures that create significant stress and anxiety. National data show high rates of psychological distress, loneliness, and diminished resilience in this population, often linked to not only high academic demands but also struggles with meaning-making. The literature revealed that existential meaning (i.e., the perception that life has coherence, purpose, and significance) and resilience (i.e., the capacity to adapt and recover from adversity) are protective factors that promote psychological well-being. Together, these constructs play a critical role in sustaining psychological well-being during the transition to higher education. This study examined how existential meaning (presence and search), resilience, and psychological well-being are related in college students. Based on the literature, the following hypotheses were proposed: the presence of existential meaning and resilience would positively correlate with psychological well-being, while the search for existential meaning would negatively correlate with psychological well-being. Upon IRB approval, instrument packets and consent forms were completed by a sample of 135 undergraduate students. Students completed the Meaning in Life Questionnaire (MLQ), the Connor-Davidson Resilience Scale (CD-RISC-25), and the Well-Being Scale (WeBS). Results supported two of the hypotheses: resilience was strongly and positively correlated with psychological well-being ($r = .681, p < .001$), and presence of meaning was positively correlated with psychological well-being ($r = .496, p < .001$). In contrast, search for meaning was not significantly correlated with psychological well-being ($r = .126, p = .073$). These findings suggest that resilience and the presence of meaning serve as protective factors for psychological well-being in college students, whereas searching for meaning may not directly predict well-being. Implications highlight the importance of fostering resilience and meaning-making in counseling and educational contexts to promote student flourishing.

Abstract Name: Are Age at Diagnosis and Long-term Mental Health Related for People with Autism Spectrum Disorder?

Though the exact number of individuals with Autism Spectrum Disorder (ASD) is unknown, the CDC estimates that 1 in 31 children (3.2%) aged 8 years old have been diagnosed with ASD, and recent population studies suggest approximately 5.4 million adults may have ASD. People with ASD report a lower quality of life than their neurotypical peers, measuring for factors like loneliness, social anxiety, support and satisfaction with life. The timing of ASD diagnosis plays a critical role in mental health outcomes; it has been shown that early diagnosis for those with ASD prompts individuals to seek ASD-related therapies that improve their mental health and encourage greater self-understanding and acceptance. People who receive an ASD diagnosis later in life do not have access to this mental health care or other early interventions. Amongst those who are diagnosed, significant gender disparities exist because of implicit bias, structural inequalities, and male-coded diagnostic criteria for ASD. Females are often misdiagnosed with other mental health issues or diagnosed later in life, impacting their mental health outcomes. This research studied the relationship between age of ASD diagnosis and mental health, and whether gender moderated that association. I recruited 80 people with ASD through social media, support groups and university classes. Participants answered questions about the age at which they were diagnosed with ASD or “suspected” they had ASD; completed The Satisfaction with Life Scale and the Generalized Self-efficacy scale; and completed a checklist of any co-occurring psychological diagnoses. I expect to find a statistically significant relationship between the age of

ASD diagnosis and measures of mental health, with the early age of diagnosis correlating to greater mental health. I predict that gender will moderate this relationship, with age of diagnosis exhibiting a stronger relationship to mental health outcomes among women than men.

Abstract Name: Decolonizing Art Education: A Comparative Study of Indigenous Beadwork in Canadian and American Art Lesson Plans

This research focuses on Canadian and American Indigenous multicultural art education methods in the 21st century, focusing on beadwork use in art lesson plans. The aim of this study is to illustrate the importance of teaching Indigenous art within the framework of social power relations in the respective countries. The art lesson plans consider Indigenous backgrounds of artworks, Smallpox (Canadian) and Miniature Wampum Belt (American), both representing beadworks commonly studied in schools. A brief introduction to multicultural art education, considering Indigenous art, will provide insight into approaches that reduce stereotyping in art education. Following, the examination of two respective art education lesson plans to demonstrate different approaches to art education regarding indigenous. While Canadian art education emphasizes the anti-racist approach considering the colonial framework, the American art education promotes diversity and inclusion, ignoring the power relations of the colonial framework. Historical and art historical studies will be utilized to discuss the artworks' respective cultural meanings. This study is important considering the existence of stereotyping in art education, a limited comparative study of art educational practices, and the need to advance Indigenous multicultural art education.

Abstract Name: Geographic Disparities in Adult Smoking Near the Tulsa–Osage County Boundary

This project examines geographic disparities in reported adult smoking rates near our community campus along the Tulsa–Osage County boundary. Using Smoking-Attributable Mortality (SAM) data for Oklahoma and Behavioral Risk Factor Surveillance System (BRFSS) survey results, local patterns will be compared to state and national trends. Smoking remains the leading cause of preventable death in the US, accounting for approximately 480,000 deaths annually, and over 16 million Americans live with smoking-related diseases. Historically, the state of Oklahoma reports adult smoking rates that are higher than national data, underscoring the need for targeted interventions. Secondhand smoke has caused an estimated 2.5 million deaths since 1964, affecting both smokers and non-smokers. Additionally, environmental concerns such as thirdhand smoke contamination and cigarette butt pollution highlight broader public health implications. Preliminary BRFSS data shows Osage County has higher rates of adults reporting a diagnosis of COPD, current smoking, mental distress, physical distress, and disability of all types compared to Tulsa County and the US average. Findings will guide campus initiatives, inform educational public health strategies, and serve as a foundation for future undergraduate research. In subsequent semesters, this data will be available for future students to use as a starting point for undergraduate research questions. Public education and

awareness of health benefits associated with smoking cessation could positively impact the surrounding community. Evidence suggests that smoke-free environments support cessation efforts, and individuals employed in smoke-free workplaces were more likely to maintain smoke-free homes. Promoting cessation and advocating for smoke-free workplace policies are evidence-based strategies to support students and the community. This project will include SAM data, BRFSS survey results, and resources from the US Office on Smoking and Health (OSH) to identify disparities and describe primary, secondary, and environmental impacts.

Abstract Name: The Impact of Mobile Methadone Units on Crime Rates

Methadone has been an effective form of medication-assisted treatment (MAT) for people suffering from opioid use disorder (OUD) since the 1960s. Given Methadone's status as a controlled substance, many doctors are unable or unwilling to prescribe it to patients. Since brick-and-mortar treatment facilities can be difficult to access, recipients also face barriers to necessary treatment. Limited access to effective treatment for OUD can lead to increased drug usage and high rates of criminality in underserved areas. A pandemic-era regulatory shift attempted to expand networks for MAT by allowing mobile methadone units (MMUs) to enter communities and provide treatment for OUD. This paper aims to assess the impact of MMU implementation on local crime. I use 2017-2024 data from the Uniform Crime Reports, which tracks monthly crime counts reported by every law enforcement agency in the United States. I use a difference-in-difference estimation strategy to determine the effect of this revised regulation relative to control localities that did not adopt MMUs as a means of treatment. I expect MMUs to decrease some low-level crime rates, such as petty theft and drug-related offenses, which are correlated with high rates of untreated substance abuse. These findings could impact the way methadone is dispensed regularly to rural communities where people struggling with OUD have persistent difficulties overcoming addiction.

Abstract Name: Lime and Phosphorus Interactions on Soil Phosphorus Availability

Production agriculture is responsible for feeding an increasing global population. Understanding how to maximize phosphorus (P) availability can ensure optimized fertilizer rates, maximized crop yield, and improved plant P nutrition. Adding fertilizer P and maintaining soil pH between 6.0 and 7.0 are two strategies used to increase P availability. However, it is often stated that adding lime and P fertilizer at the same time reduces the effectiveness of the added P fertilizer in raising soil test P (STP) levels. In this study, the effect of soil type, lime application time relative to P application time, lime application rate, P application rate, length of incubation time, and combinations thereof on STP levels were evaluated. Soil types differed in the amount of change that resulted in soil pH and STP where the soil with the greatest amount of clay was exhibited the

smallest change. Adding lime one month prior to P fertilizer resulted in a lower STP value. Adding lime or P alone increased STP. Adding both lime and P further increased STP. The higher P rate (200 lb/acre) was more impactful than the lower P rate (100 lb/acre). The four-month incubation resulted in lower STP values than the two-month incubation. Overall, applying lime at the same time as P – at the higher P rate (200 lb/acre) – was the most effective treatment combination maximizing P availability. This research suggests that adding both lime and P close to the start of plant growth would be ideal to maximize P availability to the crop.

Abstract Name: Manufacturing and High-Temperature Performance of Inconel 718 for Extreme Environments

Inconel 718, a nickel-based superalloy, is valued for its strength, corrosion resistance, and stability in extreme environments, making it essential for critical components in aerospace, energy, and nuclear applications. This study examines the oxidation behavior of Laser Powder Bed Fusion (L-PBF) manufactured Inconel 718 from 800 °C to 1000 °C to determine optimal service conditions for nuclear fasteners. Samples were polished, heat-treated, and analyzed via mass gain measurements, oxide thickness profiling, and Raman spectroscopy. Results show that 850 °C produces a stable, adherent oxide layer rich in Cr₂O₃ and Al₂O₃, balancing protection and structural integrity. Temperatures ≥950 °C accelerated oxide growth, caused blistering, and reduced scale stability, conditions that threaten mechanical performance under thermal cycling. These findings highlight the need for precise control of additive manufacturing parameters and post-processing to achieve maximum high-temperature durability, offering a pathway to reliable Inconel 718 components in next-generation reactor environments.

Abstract Name: Analysis of The Little Thumbling: A Multifaceted Ogre Against the Isolated French Peasantry

Fairy tales tell so much more than just a story, they are a reflection of what life was like for their storytellers. This paper is a reflection on The Little Thumbling, a French fairy tale that was created in the midst of great political, financial, religious, and environmental turmoil. Looking at The Little Thumbling through the lens of Marxism, and ecocriticism, the reader is challenged to think more about how The Little Thumbling symbolizes the French peasants of the 16th century's struggle with famine, sickness, and the oppressive government as shown through cannibalism, the Little Thumbling himself, and through the abandoning of the children due to an oppressive government because of the environment and quality of life. Fairy tales like The Little Thumbling are significant because they prove how the best art is created through restriction. It is art validating the struggle of real people. Peasants are crafters of the fairy tales we know and love. Learning why these stories were made and understanding what it meant to these groups of people is important for appreciating these powerful stories.

Abstract Name: Extrusion-based Additive Manufacturing of Magnetic Heat Exchange Structures for Caloric Applications

Developing sustainable, high-efficiency cooling technologies is vital to addressing 21st century energy challenges. This research focuses on magnetic refrigeration, an environmentally friendly cooling method utilizing the magnetocaloric effect to regulate temperature using magnetic fields. This approach offers greater energy efficiency than conventional vapor-compression systems by eliminating harmful refrigerants. The critical component is the regenerator, made of magnetocaloric material and transfers heat between the magnetic material and a fluid through parallel channels. Traditional designs such as packed beds of particles are prone to particle segregation, creating an undesirable pressure drop. The main goal of our research was to fix those flaws by building brand new heat exchanger structures that we could easily install and test inside a working prototype magnetic cooling machine. Our methodology involved utilizing Additive Manufacturing (AM), specifically Laser Powder Bed Fusion (L-PBF), to produce complex and customized geometries that are difficult to create with traditional methods. We tested several advanced designs, including Schwarz diamond, Gyroid lattices, and foil pin arrays. These AM regenerators were tested in a CaloriSMART test bed for experimental validation of their thermal performance. The experiments were conducted without an applied magnetic field to isolate structural effects and yielded compelling results. The foil pin array achieved a 10°C temperature span, a 66% increase over the 6°C span of the packed particle bed baseline. Both the foil pin and Schwarz diamond structures demonstrated an 8% increase in cold blow effectiveness. Furthermore, the AM designs significantly reduced pressure losses. At a mass flow rate of 0.00299 kg/s, the foil pin array reduced the pressure drop by 41.9% compared to the packed bed baseline (24.70 kPa vs. 42.55 kPa). Ongoing research aims to democratize access to this technology through exploring Fused Filament Fabrication (FFF) as a portable and low-cost alternative to L-PBF.

Abstract Name: Cancer Disparities in Virginia: A Geospatial Analysis of Incidence, Mortality, and Environmental Determinants (2011–2020)

Cancer remains a major public health challenge in Virginia, with clear differences in who is affected and where the burden is highest. Using ten years of statewide cancer data, this project examines how geography, environment, and community characteristics shape cancer outcomes across Virginia. Cancer incidence and mortality data from the Virginia Cancer Registry (2011–2020) were summarized for every county and health district, and stage-at-diagnosis patterns were incorporated to assess where late detection is most common. To understand why cancer risk varies across regions, key demographic and socioeconomic indicators—such as poverty levels, educational attainment, age structure, and racial composition—were obtained from U.S. Census datasets. Environmental exposure measures, including fine particulate matter (PM_{2.5}), nitrogen

dioxide (NO₂), and water quality indicators, were retrieved using Google Earth Engine. To analyze these multiple layers of information, the study applied Bayesian hierarchical spatial models, which allowed for more stable county-level estimates and provided relative risk predictions and exceedance probabilities. These results were visualized through interactive web-based mapping dashboards designed to help decision-makers explore regional patterns and identify areas of concern. Strong geographic disparities emerged across the state. Lung cancer incidence and mortality were highest in Southwest Virginia and Southside counties, where smoking prevalence, poverty rates, and PM2.5 exposure were also elevated. Colorectal cancer risk was greater in rural Southside health districts, which also experienced higher rates of late-stage diagnosis. Breast cancer incidence was greatest in urban and coastal areas, while prostate cancer incidence was significantly higher in predominantly African American communities in Southside and Hampton Roads. Environmental exposures remained significant predictors of cancer risk even after accounting for socioeconomic conditions. Overall, this project highlights how environmental and social factors interact to shape cancer disparities in Virginia and demonstrates how geospatial tools can support targeted cancer prevention and control efforts.

Abstract Name: A Scalable, Modular UAV Platform for Autonomous Flight Research

This project explores the development of a modular, low-cost unmanned aerial vehicle (UAV) platform designed to enable scalable experimentation in autonomous flight and machine learning. The goal is to determine whether a fully open-source, reconfigurable drone system can achieve performance comparable to proprietary systems while remaining cost-effective and adaptable for diverse research applications. Current UAV research often depends on expensive, proprietary systems that limit adaptability and replication. Existing open-source UAV efforts have emphasized accessibility, but each design remains constrained to limited applications, sacrificing flexibility for cost. This work addresses that gap by developing a robust, open-source, customizable platform that supports diverse research tasks such as multi-agent perception and coordination. The methodology combines computer-aided design, iterative prototyping, and experimental validation. The UAV's carbon-fiber frame was enhanced with 3D-printed components including battery and sensor mounts, propeller guards, and landing gear, which allowed rapid modification and replacement. Finite Element Analysis (FEA) simulations in SolidWorks assessed structural durability under applied forces, while physical indoor and outdoor tests evaluated hover stability, vibration control, and sensor reliability in various environments. The final design achieved a total weight of 1.3 kg, 13-minute hover time, and an estimated total cost of \$2,000, including an onboard computer and electronics. This represents a significant reduction in material expenses while simultaneously optimizing functionality. Preliminary results demonstrate mechanical durability, flight stability, and adaptable sensor integration for various autonomous tasks. Future testing will extend to multi-drone coordination, perception, and heterogeneous collaboration. These results will be discussed in the context of advancing embodied AI experimentation, with emphasis on the platform's reproducibility, scalability, and ability to translate models from simulation to real-world deployment. By presenting a validated, affordable UAV platform optimized for autonomy research, this project contributes a practical and flexible hardware foundation for the next generation of machine learning and robotics studies.

Abstract Name: Alphonse Mucha: The Designer Creating Art in Every Corner of Life

Alphonse Mucha was an incredibly influential designer who is most well known for his iconic embellished style. His style represented the Art Nouveau movement of 1890 to 1914, and he is often thought of as one of the most important Art Nouveau designers. His Catholic upbringing was a major influence on his life, and it inspired him to create art for the purpose of enlightenment. After creating an influential poster in Paris, Mucha became extremely popular. While he is known for his posters depicting women and flowers, he created a broad range of designs in many different mediums. Mucha was so influential that his style was studied in both Europe and America. Furthermore, his designs incorporated his Catholic beliefs, along with the symbolism, mysticism, and Freemason ideals that he learned in Paris. When Mucha skillfully blended these ideals into his art, even simple furniture and advertisements felt alive. Additionally, Mucha was fiercely tied to his homeland and the culture of the Czech people. Not only did he work to inspire the Czech people, but he also encouraged their culture to endure. Mucha's belief that beauty could enlighten people led him to create visually stunning designs with the intention of brightening the world around him.

Abstract Name: When AI Asks Instead of Answers: Socratic LLM Tutoring with Adaptive Difficulty and Historical Pattern Recognition

Computer science theory courses, particularly automata theory, present significant pedagogical challenges due to their abstract nature and the difficulty students face in developing formal reasoning skills. Traditional teaching methods often fail to provide the individualized guidance necessary for students to master concepts like Deterministic Finite Automata (DFA). This research introduces TheoTeach, an intelligent tutoring system that combines large language models (LLMs) with Socratic pedagogy, adaptive difficulty scaling, and historical learning to create a personalized educational experience for automata theory students. TheoTeach employs a local LLM (Mistral via Ollama) configured with Socratic questioning principles to guide students through DFA concepts without directly providing answers. The system implements a novel multi-dimensional student modeling approach that tracks mastery levels across specific topics (DFA construction, minimization, product automata) on a 0-5 scale. Using this profile data, the system dynamically adjusts question difficulty and intervention strategies in real-time, ensuring students work within their zone of proximal development. A key innovation is the historical learning engine, which analyzes past test data, common student errors, and successful solution patterns to inform tutoring strategies. The system integrates automata-lib for automated answer verification, enabling a Socratic enforcement layer that ensures responses remain question-based while validating correctness. Additionally, JFLAP integration provides visual feedback for DFA construction exercises. Preliminary results demonstrate that personalized, adaptive tutoring significantly improves student engagement and conceptual understanding compared to static educational resources. This research contributes a scalable framework for LLM-based tutoring in formal computer science subjects, demonstrating how historical data can enhance AI-driven personalized education while maintaining pedagogically sound Socratic methodology.

Abstract Name: Cardiac Specific Delivery of VEGF-A to Improve Perfusion and Prevent Remodeling in Ischemic Heart Tissue

Myocardial infarction results in irreversible loss of cardiomyocytes, microvascular collapse, and gradual fibrotic remodeling, diminishing ventricular function. While reperfusion and pharmacological treatment enhance survival rates, they fail to rehabilitate injured myocardium or prevent the progression of long-term fibrosis. Prior regenerative approaches utilizing stem cells, recombinant growth factors, or early viral vectors have had variable results owing to restricted engraftment, brief protein half-lives, systemic exposure, and insufficient targeting of cardiomyocytes. To overcome these obstacles, we developed an endocardium-targeted gene therapy that administers VEGF-A directly to the viable myocardium in the infarct border zone. We seek to improve circulation, reduce fibrosis, and maintain ventricular architecture by designing an AAV9 vector that encodes VEGF-A regulated by the cardiac troponin T promoter. The therapy aims to restrict gene expression to endocardium while preventing unintended angiogenesis in other tissues. In vitro investigations will assess promoter specificity, transduction efficiency, VEGF-A production, and resistance to hypoxia-reoxygenation injury using primary neonatal rat cardiomyocytes. Supplementary tests employing human endothelial cells will evaluate angiogenic activity by tube formation, migration, and proliferation assessments. In vivo validation will be performed using a LAD ligation mouse model. Animals will have intramyocardial AAV9 injections followed by serial echocardiography to evaluate ejection fraction, wall motion, and ventricular dilatation. Histological evaluations encompassing Masson's trichrome, CD31, and TUNEL staining will measure fibrosis, microvascular density, and apoptosis. We anticipate that localized, sustained production of VEGF-A will enhance capillary development, diminish cardiomyocyte apoptosis, limit scar expansion, and improve ventricular function compared to untreated and vector-only controls. This study proposes that integrating cell-type-specific transcriptional regulation with the inherent cardiotropic properties of AAV9 is a viable approach for attaining safe, targeted, and long-lasting molecular repair following myocardial infarction. This strategy could enhance cardiac gene therapy by offering a locally accurate and therapeutically scalable technique for supporting tissue preservation after ischemic injury.

Abstract Name: From Ritual to Relic: Jivaroan and Māori Head Shrinking Practices in Western Museums

This study discusses the ceremonial preservation of human heads by the Jivaroan peoples of the Amazon and the Māori of New Zealand as reflections of deeply rooted spiritual systems, cultural values, and demonstrations of social rank. As a comparative cultural analysis, these two Indigenous groups side by side highlight both the distinct meanings behind their respective traditions and the parallel ways in which Western colonial forces misrepresented, commodified, and ultimately dehumanized them. This research will also address the emergence of Western ethnographic collecting and the cultural violence that was inflicted on ancient Jivaroan and Māori traditions through these practices. To examine such practices in a contemporary context, I conducted firsthand observations at the Mabee-Gerrer Museum in Shawnee, Oklahoma. The museum displays two Jivaroan shrunken heads, offering a clear example of how colonial collecting practices continue to shape the presentation and interpretation of Indigenous artifacts within Western institutions. Furthermore this study incorporates supporting research from anthropological and historical context, ethnographic accounts, and postcolonial theory. Such an interdisciplinary approach allows for an examination

of Indigenous worldviews on their own terms, while simultaneously analyzing the invasive impact of European colonialism and ethnographic “collecting.” From the eighteenth to the twentieth century, the extraction of artifacts and cultural information was largely carried out by Western museums and private European collectors seeking objects that could be displayed as curiosities or exotic trophies. This research emphasizes how the appropriation and exhibition of preserved heads for spectacle and profit not only distorted and brutalized Indigenous practices but also reinforced harmful colonial narratives that depicted Indigenous peoples as violent, primitive, and inherently “other.” Ultimately, this research explores the mistreatment and neglect of these cultural traditions, highlighting how profoundly colonial trade networks and ethnographic collecting have dehumanized ancient Indigenous practices and shaped modern misunderstandings of these cultures.

Abstract Name: SELECTION OF TACKIFIERS FOR ENGINEERING BIODEGRADABLE HYDROMULCH

Erosion control is a vital component of sustainable agriculture, helping to prevent soil loss, conserve water, and improve crop productivity. Currently, low-density polyethylene (LDPE) plastic mulch is the most widely used material for this purpose. However, its negative environmental impact and costly removal highlight the need for biodegradable alternatives. Hydromulches (HMs)—spray-applied mixtures of fibers, water, and tackifiers—offer a promising solution because they stabilize soil while naturally degrading over time. Recent studies suggest that biodegradable HMs can perform comparably to polyethylene mulch, though their success depends heavily on the choice of tackifier. This project explores environmentally friendly and cost-effective tackifiers for hydromulch development. Tackifiers act as the “glue” that binds fibers together, making their selection critical to mulch performance. Multiple formulations were prepared using uncoated paper and finely ground hemp hurds as fiber sources. These mixtures were combined with water at a 35:1 ratio (water weight to dry weight), blended into a slurry, and dried into square mulch samples. Mechanical and physical properties—including tensile strength, puncture resistance, water-holding capacity, and density—were measured to evaluate the effects of varying fiber and tackifier concentrations. Preliminary results show that xanthan gum provides the highest tensile strength and puncture resistance at higher concentrations (5%). Hemp hurds increased tensile strength in xanthan gum formulations but reduced puncture resistance. These findings were compared to a control of 100% paper with no tackifier or hemp hurds. Ongoing research will test starch-based tackifiers, with the expectation that starch will perform similarly or better than xanthan gum. It is anticipated that higher tackifier concentrations combined with lower hemp hurd percentages will continue to enhance mulch properties. This work advances the development of biodegradable hydromulches as sustainable, cost-effective alternatives to plastic mulch in agriculture.

Abstract Name: Evaluating the Performance Characteristics of Sponge Spicule Tempered Pottery

How tempers affect performance characteristics in pottery is a popular topic in experimental archaeology literature. While archaeologists have examined the effects of many tempering agents, sponge spicules have received very little attention, even though they are found in archaeological samples across the globe. This research uses an experimental archaeology approach to examine the impact of sponge spicules on the performance characteristics of strength and toughness in pottery. An experimental assemblage of briquettes was created using a South Florida smectite clay and sponge spicules. The briquettes were uniformly cut to 100mm x 20mm x 11mm following standard protocols in archaeological testing and were fired to a temperature of 700°C to mimic the average temperature of open pit fires. After firing, the briquettes were subjected to a three-point bend test using a Mark-10 ESM303 single column motorized test stand in to test whether spicules increased or decreased the characteristics of strength and toughness relative to sand-tempered and untempered samples. The data from these tests was used to calculate the modulus of rupture and work of fracture for each briquette. These findings suggest that differences in peak compression and work of fracture between sand-tempered and spiculate-tempered test groups are statistically significant. Overall, the data collected suggests that sponge spicules increase the performance characteristic of toughness, potentially increasing vessel use-life following crack propagation.

Abstract Name: Variations in T-lymphocyte and Natural Killer Cell Populations Between the Melanoma Microenvironment and Peripheral Blood

Melanoma is an aggressive disease due to its propensity to metastasize. The tumor also has the ability to alter the types of immune cells within the tumor microenvironment (TME). Immunotherapy is the gold standard for treating metastasized melanoma as it reactivates or stimulates the patient's own cells to help them fight the tumor, but it is inconsistent across populations and individuals. Evaluating immune cells in both the circulation and the tumor itself will help determine how local tumor-driven immune modulation reflects or diverges from systemic immune changes. To explore this, peripheral blood and tumor tissue samples from C57BL/6 mice subcutaneously injected with Yale University Mouse Melanoma cells as an established mouse model of melanoma will be collected to compare the populations of T-lymphocytes (T-cells) and natural killer cells (NK cells). In addition, as immunotherapy often utilizes the T-cells and NK cells to combat the tumor, PD-1 expression will also be assessed as melanoma may lead to an increase in PD-1 expression to suppress T-cell and NK cell activity. Samples will be analyzed using flow cytometry and compared using mean fluorescence and Chi-squared tests. This study will provide information regarding how the tumor changes the composition of immune cells from the blood to better evade defenses, giving a potential explanation for why certain patients respond poorly to immunotherapy and informing future strategies to enhance treatment efficacy.

Abstract Name: How the successes of queer people get undermined due to race, disabilities, or age.

This research focuses on subtle discrimination in interdisciplinary activism. Historically, activists would be outwardly discriminated against for their sexuality or gender. As of the past 15-20 years, the discrimination has since shifted towards associated identities such as race, age, or disability. This grouping focuses primarily on female & queer activists, as research on men of color in activism is limited. Several organizations that have made incredible progress in activism communities were started by powerful, young, disabled women of color that have since been forgotten due to the discriminatory shadow casted over their work. These results are significant because the work and experiences of these women would be monumentally beneficial to currently failing activism organizations. This lack of progress is causing the gap between minorities to grow even larger. After years of protesting, open and obvious discrimination against queer identities has become less normalized. However, the hate behind such discrimination did not go away. Instead, it was put towards other mechanisms of social ostracization. Data collected through a series of interviews with several different female activists of varying ages, races, and/or disabilities brings to light the fact that despite working with other queer people, women of color often will experience hate, harassment, or discrimination by older, white, able-bodied individuals. Our research covers not only the successes of these women that have since been subtracted from the public eye and the discrimination they've faced, but also their experiences in the 1990's DC intersectional activism community.

Abstract Name: Executive Compensation Structure and Earnings Management Around Equity Issuance

This study examines the relationship between executive compensation structure and earnings management over the last five years using a sample of more than 100 manufacturing firms in the S&P 500 from 2021-2025. The analysis provides evidence that executives engage in earnings management around firm-specific corporate events, particularly seasoned equity offerings. The results show that executives with a higher proportion of option-based or equity-based compensation are more likely to manage earnings prior to issuing equity compared with executives whose compensation is primarily cash-based. In addition, higher levels of firm-related executive wealth are associated with greater earnings management. Overall, the findings suggest that equity-linked compensation intensifies managerial incentives to influence reported earnings during key financing decisions.

Abstract Name: High School Bridge to STEM Teacher Career Exploration Program Pre-Post Survey Results: Implications for Driving Interest in Teaching Mathematics

The Learning Policy Institute (2025) recently reported that teacher shortages were due to fewer interests in the teaching profession and increased rates of practicing professionals leaving the ranks. Furthermore, it was suggested that trends in high school students considering teaching and teacher education majors have been at an all time low. Grounded in vocation-fit theories, this study aimed to identify the factors and considerations that can be used as leverage to attract high school students. After pre-post data was subjected to a related samples Wilcoxon signed-rank test and the results revealed that Biology was more likely to be sought as a teaching discipline and jobs that require communication and collaboration with people of diverse backgrounds. Furthermore, four factors mirrored motivators typically ranked high by in-service teachers. Implications for how to attract talented math teachers are discussed.

Abstract Name: USP11 siRNA Knockdown Improves Efficacy of Chemotherapy in Hepatocellular Carcinoma

Hepatocellular carcinoma (HCC) is the most common form of primary liver cancer and the third leading cause of cancer-related deaths worldwide. Despite advances in surgery and systemic therapy, patient outcomes remain poor, and the current standard treatment (sorafenib) provides only modest survival benefits with significant side effects. This project investigates the therapeutic potential of small interfering RNA (siRNA) targeting Ubiquitin-Specific Protease 11 (USP11), a deubiquitinase that regulates the cell cycle, DNA repair, and oncogenic signaling. USP11 is upregulated in multiple HCC cell lines and contributes to tumor growth and metastasis; therefore, its silencing may enhance the response to chemotherapy. To evaluate this hypothesis, USP11-targeting siRNA was transfected into PLC/PRF/5 (PP5), Hep3B, and C3A HCC cell lines. Quantitative RT-PCR confirmed USP11 knockdown to less than 10% of untreated controls. MTS assays demonstrated that USP11 silencing lowered the IC₅₀ of sorafenib in both PP5 and Hep3B cells, indicating increased drug sensitivity. Most recently, GalNAc-conjugated USP11 siRNA achieved effective knockdown in PP5 cells without lipid-based transfection reagents, validating receptor-mediated delivery as a less cytotoxic and more consistent approach. Future work will expand GalNAc-siRNA testing to additional HCC cell lines and assess combination therapy with sorafenib. In collaboration with the Parkman Lab, in vivo studies will evaluate therapeutic efficacy in mouse xenograft models. Our research aims to establish USP11 as a viable therapeutic target and advance siRNA-based strategies toward safer, more effective treatments for liver cancer.

Abstract Name: Drawn to Donate

This project explores how horror-themed, illustrated storytelling can transform the fear of giving blood into a communal, even playful Halloween experience, similar to the way haunted houses or trick-or-treating turn fear into fun. My central research question asks: How can the fear of giving blood be transformed into a fun, shared Halloween experience that encourages community participation in blood drives? The short film is fully illustrated in a dark, storybook aesthetic inspired by *The Babadook*, *Mother* LA's *Mother Book*, and the tradition of unsettling cautionary picture books. These influences shape a visual world filled with deep shadows, textured drawings, and childlike yet eerie compositions. By using genres that make fear theatrical and collective, the film reframes blood donation not as a medical ordeal but as part of a shared seasonal ritual, where bravery and community naturally intersect. Methodologically, the project uses sequential hand-drawn illustrations animated through storybook-style transitions. This tactile approach reinforces atmospheric horror without needing gore or graphic imagery. Throughout the film, real public-health information is incorporated, including statistics on the significant drop in blood donations during the holiday season and the high rates of needle-related anxiety among young adults. These facts serve as emotional anchors, highlighting that while needles may feel frightening, the far greater fear is needing blood when none is available. The project aims to evaluate how blending horror aesthetics with community-centered themes can make health communication more engaging, memorable, and actionable for college-aged viewers. By positioning blood donation as a collective Halloween challenge rather than a solitary medical task, the film seeks to shift perceptions and encourage participation. The conference presentation will discuss the film's development process, genre influences, and the potential for illustrated horror to function as effective public-service communication.

Abstract Name: Breaking the Silence: How Sociocultural Factors Influence Family Conversations About Reproductive Health Among College-Aged Women

Reproductive healthcare decisions among college aged women are influenced by various sociocultural factors such as race, economic status, and region origin. Prior studies have proven that these factors shape contraceptive use and sexual health behaviors. This study seeks to answer the question: How do sociocultural factors affect the rate at which college aged women talk to their families about their reproductive health choices? Through a mixed methods approach, data will be collected through surveys taken by LSU students. The surveys aim to assess demographic background, access to healthcare resources, economic status, and reproductive health choices. By analyzing the patterns found within the data, this study aims to highlight the disparities in reproductive healthcare choices, contributing to a broader understanding of the factors that influence college aged women in making these choices. Findings from this study may inform health education initiatives amongst a range of different college campuses, as well as aid campus resources in being more effective. Doing this will support diverse student populations in making informed reproductive health decisions.

Abstract Name: Characterization and Differentiation of Commercial Honey Samples Using ATR-FTIR Spectroscopy and Multivariate Analysis

Honey is a natural sweetener valued for its taste and health benefits, making it a high-demand product worldwide. However, its commercial importance also makes it susceptible to adulteration, highlighting the need for reliable authentication methods. This study analyzed 68 honey samples from different floral and geographical origins using Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) spectroscopy and X-ray Fluorescence (XRF), supported by multivariate statistical tools such as Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA). ATR-FTIR spectra revealed characteristic absorption bands associated with sugars and moisture, particularly hydroxyl (-OH), aliphatic (-CH), and carbonyl (C=O) groups. Differences in peak positions and intensities suggested variations in sugar composition, floral source, and processing techniques. XRF detected elemental markers including aluminum (Al), silicon (Si), phosphorus (P), and magnesium (Mg), with distinct patterns linked to geography and brand. PCA and HCA provided clear clustering patterns, grouping honeys with similar chemical traits and revealing outliers. Together, ATR-FTIR and XRF demonstrate powerful complementary tools for honey classification, authentication, and traceability, highlighting the influence of geographical and botanical variation on honey composition.

Abstract Name: Creation and Representation: Rhetorical Effectiveness of Audience Construction within the Deaf Vlogging Community

Various types of minority groups use YouTube as a platform to share their stories, grow their brands, and develop communities online. While there has been previous research on Deaf-focused videos and their presence on the platform, the focus has been on the types of videos posted, the creator's purpose for video-making, and how that content engages with existing representation and stigma of the community (Hibbard & Fels, 2011; Li et al., 2022; Souza et al., 2023; Martzos et al., 2021; Oliveira et al., 2021; Parton, 2016). Additionally, for many minorities, there has been research on how online communities can provide spaces for open conversation that may not be possible due to location, disability, or censorship (Case, 2012). This research will focus on the Deaf vlogging community in the United States and how they reach their intended audiences to establish communities in online spaces on YouTube despite language and accessibility barriers. Creator demographic data will be collected through channel and video descriptions to understand identification with the Deaf, hard-of-hearing, and cochlear-implant user communities. This paper will also conduct content and genre analysis of 60 videos from 30 selected Deaf vlogging channels to analyze how creators use audiovisual cues and video editing to construct audiences and communicate with them. Lastly, the data from 100 comments will be pulled from each of the 60 comment sections using the YouTube Data Tools modules (Reider, 2015). This research argues that creators should consider their purpose for posting

content and their intended audience when making audiovisual cue editing decisions, as the accessibility of their videos may support or restrict audience interactions.

Abstract Name: Investigation of chemogenetically-mediated PFC Activation to Rescue Adolescent Ethanol Induced Memory Deficits

The proposed study will demonstrate proof of concept that chemogenetic activation of neurons can increase myelin production by oligodendrocytes and improve memory in an object recognition task. This project is part of a larger study to investigate using chemogenetic Gq Designer Receptor Exclusively Activated by Designer Drugs (DREADD) activation of prefrontal cortex neurons following adolescent binge ethanol to assess whether activity-dependent myelination can promote oligodendrocyte maturation and the increase proliferation of myelin. A Gq DREADD virus will be injected into the medial PFC of 21 adult C57BL/6J mice. Three weeks after viral delivery, a Gq DREADD will be activated using DCZ or vehicle using two paradigms to induce activity-dependent myelination: Group 1 will receive vehicle (saline) for 15 days, Group 2 will receive DCZ for 15 days, and Group 3 will receive DCZ for 8 days. To evaluate memory, a novel object recognition test will be administered. After behavioral assessments, brain tissue will be collected, and immunohistochemistry will be run to identify changes in myelination and to ensure correct delivery of the viral injection. To visualize changes in myelination, dual staining for mCherry (for viral confirmation) and myelin basic protein will be conducted. A previous small pilot study (n=9) showed no significant differences between the vehicle and DCZ-treated groups, however a trend of increased immunofluorescence was noted in the 15-day treated group as compared to controls. Given the increased power of the current proposed study, we expect to observe a stronger increase in MBP immunofluorescence as well as improved performance on behavioral memory tasks.

Abstract Name: Signaling Pathways Driving BATF3 Expression in Human T cells.

Background: Basic leucine zipper transcriptional factor 3 (BATF3) is a part of the AP-1 family and has been linked to memory CD8 T cell development and recall responses in murine models. During infection, T cells multiply to achieve the numbers required to fight infection followed by contraction. A small portion of these T-cells are retained to make memory T-cells. In murine models, it was shown that when BATF3 is repressed, not as many cells make it out of the naive stage and into central memory. Cells expressing BATF3 live longer and proliferate more. BATF3 has been discovered in human T cells, however, the immunobiology of BATF3 in human T cells is unknown. We discovered that BATF3 is robustly upregulated in human CD4 and CD8 T-cells upon activation. Since the upstream cues governing this induction are unclear, we hypothesized that integrated TCR–CD28 signaling promote a memory-precursor program by upregulating BATF3. Method: To test this hypothesis, we isolated healthy donor T cells from peripheral blood mononuclear cells, and activated them with anti-CD3+CD28, in the presence of pathway-specific inhibitors (MAPK, PI3K-Akt, JAK-STAT and NF- κ B) and quantified BATF3 by flow cytometry. Results: Inhibition of MAPK or JAK–STAT, but not PI3K–AKT or NF- κ B, markedly attenuated BATF3 upregulation in both CD4⁺ and CD8⁺ T cells, indicating that MAPK and pro-inflammatory cytokine–STAT signaling converge to drive BATF3 expression in human T cells and potentially bias effector-to-memory fate.

Abstract Name: Exploring Plant Interactions Under Salt Stress: Above- and Below-Ground Effects

Increased salt in the soil, driven by climate change, poses a growing threat to agricultural productivity and ecological stability. This environmental stressor alters the production of plant specialized metabolites, which mediate communication with other organisms. Key interactions affected include herbivory dynamics and soil microbial symbioses. Although many studies have investigated plant-insect and plant-microbe interactions in isolation, few have examined how above- and below-ground relationships are impacted by salt stress within an integrated ecosystem context. This study aims to evaluate the role of symbiotic microbes in mediating plant responses to salt and herbivore stress, using species in the genera *Chamaecrista* and *Senna* of the Fabaceae family as model species. While both genera associate with arbuscular mycorrhizal fungi, only *Chamaecrista* forms symbioses with nitrogen-fixing *Rhizobia* bacteria. Seedlings will be grown under combinations of soil microbial presence/absence, moderate salt stress, and exposure to a generalist herbivore. Preliminary trials tested various seed scarification methods to improve germination rates, revealing higher

germination rate in *Senna* than in *Chamaecrista*. If *Chamaecrista* germination remains inconsistent, the study will expand to include other rhizobia-associated Fabaceae genera. By integrating above- and belowground interactions, this research aims to highlight how beneficial microbes enhance plant resilience to abiotic and biotic stressors. These findings will provide ecological insight while contributing to the development of agricultural strategies in combatting increasingly saline soils.

Abstract Name: SIRP γ restricts human CD8 T-cells effector differentiation under suboptimal TCR-signaling

Signal regulatory protein gamma (SIRP γ) is a T-cell-restricted surface receptor that has been poorly understood in its vital role in human CD8 T cell differentiation. Individuals demonstrated a wide variety of SIRP γ expression, aligning with specific CD8 T cell differentiation states. Increased presence of CD27⁻CD45RO⁻ terminally differentiated CD8 T cells was observed in individuals with low SIRP γ levels. In contrast, high expressors primarily harbor central memory and naive cell populations. The examination of SIRP γ function was performed on human naïve CD8 T cells through siRNA-mediated knockdown. When TCR stimulation was suboptimal, SIRP γ knockdown induced strong effector-like differentiation characterized by increased CD45RO expression, elevated T-bet levels, and amplified production of TNF- α , IFN- γ , and Granzyme B. CD47 blockade did not reproduce the same effects, suggesting a CD47-independent mechanism. The collective findings institute SIRP γ as a negative regulator of CD8⁺ T cell effector programming under suboptimal conditions. Variability in individual SIRP γ expression has the potential to affect the immune homeostasis and immunopathology susceptibility. Potentially, SIRP γ can serve as a therapeutic target in environments relating to dysregulated T cell activity.

Abstract Name: Incorporating a Nucleophilic Heterocycle to Expand the Structural Diversity of an Antimalarial Protease Inhibitor Scaffold

Plasmodium falciparum is the causative agent of the most serious form of human malaria, a parasitic disease estimated to kill 500,000 people annually. We are studying falcilysin (FLN), a metalloprotease required for parasite survival in the human host. Previous work in our group on a piperazine-based hydroxamic acid scaffold identified a subset of inhibitors with promising activity against FLN and cultured *P. falciparum*. We previously found that installation of bulky aromatic substituents at the N4 position of the scaffold results in potent FLN inhibition. However, the low reactivity of these aromatic substituents limits our ability to make

structural changes and to further optimize this part of the scaffold. To address this limitation, we replaced a phenyl moiety with a 5-membered cyclic amine at the N4 position of the scaffold. This allowed for efficient functionalization of the amine by subsequent reaction with a structurally diverse set of commercially available electrophiles. We used this strategy to generate a series of 15 new inhibitors, and this approach was highly successful and identified our 2 most potent inhibitors to date. Our initial data suggests that electron withdrawing substituents at the meta and para position increase activity against FLN, and we also found that certain bulky substituents were well tolerated. In addition, we found that both amide and sulfonamide linkages to these substituents were productive. These studies expand on our previous work by further detailing the structure-activity relationships (SAR) at the N4 position of our scaffold, and these results will guide future optimization efforts.

Abstract Name: Influence Of Partial Versus Exclusively Explosive Sets Of Upper- And Lower-Body Resistance Exercise On Metabolic Rate

Resistance exercise performed with exclusively explosive reps increases metabolic rate, but performing entire sets explosively can be exhausting/unfeasible. PURPOSE: We examined whether sets of squats and bench press using only partial explosive reps could increase metabolic rate similar to exclusive sets using all explosive. METHODS: 7 men (20 ± 0.9 yrs; 82 ± 12 kg; 181 ± 5 cm) performed 4 protocols of 4x8 reps of squat and bench press. Two of the protocols were work-matched using 50% of maximal strength (1-RM), with one of them using exclusively explosive reps (EXPL) and the other 3 explosive reps immediately followed by 5 recreational (Partial 3/5-50%). We also included an additional partial session using 3 explosive with 50% of 1-RM followed by 5 recreational with 61.2% (Partial 3/5-61%). This protocol was work-matched with a session of exclusively recreational reps using 57% of 1-RM (REC). Subjects' 1-RM was determined on a squat machine and barbell bench press, and peak power was determined using a weightlifting accelerometer. Repetition speed, ROM, and rest intervals were standardized among protocols. Total work (reps x sets x load) among the protocols was: (REC=3/5-61%) > (EXPL=3/5-50%). Expired air was collected 15min before, during, and 30min after using a metabolic cart. Data were analyzed using a 2-way repeated measures ANOVA with Tukey's HSD post hoc. We hypothesized that EXPL reps would increase metabolic rate: EXPL=3/5-61% > 3/5-50% = REC. RESULTS: Rates of oxygen consumption ($\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) were significantly greater ($p \leq 0.05$) during sets 1-4 of EXPL compared to Partial 3/5-50% and REC, and Partial 3/5-61% was greater compared to REC. When corresponding REC total liters consumed were subtracted, deltas were significantly greater: EXPL (1.9 ± 0.6 L) = 3/5-61% (1.8 ± 0.7 L) > 3/5-50% (0.6 ± 0.6 L). CONCLUSION: Partial sets of squats and bench press using only 3 explosive reps may be sufficient for enhancing metabolic rate, while improving workout feasibility.

Abstract Name: Language in Family Court

Perceptions of children, their potential, and their needs are shaped by the language we use about them, particularly in parenting and as seen in court proceedings. Two opposing frameworks that frequently surface in these conversations are the child-centered and deficit-based languages. This descriptive study focuses on the use of deficit-based language in family court proceedings and how it affects children's well-being. Student researchers test three research hypotheses regarding language and its perceived impact on the parents, children, and outcomes of the proceedings. Over 50 participants are identified who have been involved in a family court proceeding that involves children, such as social workers/custody evaluators, attorneys, judges, parents, family/friend(s) and individuals who were children at the time of a child custody case. The student researchers use exploratory design for this study to explore how communication in court-involved family cases shapes the experiences of families and the professionals who work with them. Because this topic has limited existing research and involves multiple viewpoints, an exploratory approach allows the researchers to identify patterns, relationships, and concerns that may not yet be well-documented. This study uses a non-probability sampling approach, relying mainly on purposive sampling to reach adults who experienced court involvement in their families, parents who participated in custody processes, and professionals working in the court system. The results of the study improve knowledge of the experiences of family court hearings involving deficit-based language in various contexts and the potential effects they may have on children and families. Professionals gain an understanding of the factors involved and make necessary adjustments to future child custody cases based on the feedback provided by the participants. Additionally, court staff is able to utilize the results as testimony and educate anyone who would be interested in this study about the value of utilizing child-centered language.

Abstract Name: The Last of Us – The Sequel: The Quest for Uninfected Monarch Butterflies in Cuba

The monarch butterfly (*Danaus plexippus*) has become a model organism for studying host-parasite dynamics, particularly infections caused by *Ophryocystis elektroscirrha* (OE). In our previous research conducted in South Florida, we sampled monarchs from urban butterfly gardens in Miami and from natural habitats in the Everglades. Most monarchs collected from urban areas showed high OE infection levels, while monarchs from the Everglades showed no detectable spores (OE). To expand the geographical scope of this work, we conducted additional sampling in Cuba to determine whether OE is present in Caribbean monarch populations. Using standardized tape-sampling methods, we collected and screened monarchs from multiple Cuban locations. Although a few monarchs tested positive for OE, the majority showed no detectable infection. OE was present in Cuba but at a much lower frequency than in Miami's urban populations and closer to the patterns observed in the Everglades. This extended dataset allows for broader comparisons of OE prevalence across urban, natural, and international environments. By documenting infection levels in these distinct regions, this study provides updated insights into the distribution of OE in monarch populations across South Florida and Cuba.

Abstract Name: LAT1 Inhibition Impairs Metabolism and Proliferation in Colorectal Cancer

There is a critical unmet need to provide novel therapies for Colorectal Cancer (CRC) patients resistant to current treatment options. Immune checkpoint inhibitor (ICI) therapy is a novel modality for CRC treatment; however, most CRC patients (85%) have microsatellite stable (MSS) CRC, which makes them ineligible for current ICI treatments. Our lab has demonstrated that large amino acid transporter 1 (LAT1;SLC7A5) expression is enriched in CRC tumors compared to matched adjacent normal tissues. Furthermore, JPH203, a LAT1 inhibitor, was determined to reduce amino acid uptake, suppress cellular proliferation, slow tumor growth, and promote immunogenic tumor microenvironment formation in syngeneic in vivo tumor models. We wanted to functionally validate these observations by conducting knockdowns of LAT1 expression using a lentiviral vector to assess the role of LAT1 in CRC. Using LAT1 knockdown cell lines (shLAT1), we performed experiments to determine cellular proliferation, amino acid uptake, and metabolic energy phenotype in comparison to scramble control and wild-type cells. We found that shLAT1 significantly decreased cellular proliferation, reduced glycolytic energy potential, and reduced cellular amino acid uptake compared to scramble control and wild-type CRC cells. Future studies will assess how shLAT1 influences immune cell infiltrates in orthotopic in vivo animal models.

Abstract Name: Impact of Age and Light Intensity on Blue-Light-Induced RGC Dysfunction

The increasing prevalence of artificial blue light (ABL) exposure from electronic devices and artificial lighting has raised concerns regarding its potential harm on the health and integrity of the eye. Chronic exposure to ABL has been found to negatively impact retinal health through mechanisms of oxidative stress, cellular apoptosis, and loss of function. Retinal Ganglion Cells (RGCs) combine signals from photoreceptors and excitatory/inhibitory signals generated through retinal processing to transmit both visual information to the brain, and modulate non-visual forming functions such as circadian rhythm, alertness, and mood-related behaviors. A subset of intrinsically photosensitive RGCs (ipRGCs), which express the photopigment of melanopsin, are particularly sensitive to blue-wavelength light and may exhibit early functional vulnerability with chronic exposure. The main goal of this study is to investigate how age at the time of exposure, light intensity, and duration of exposure influence susceptibility to blue-light-induced RGC dysfunction. C57BL/6J mice from two age groups, juvenile and adult, were exposed to either low intensity (600 lux) LED blue light for a short period of 3 consecutive days, or high intensity (1100 lux) LED blue light for a longer period of 7 consecutive days, with 12 hours of exposure per day. Functional changes were measured through Pattern Electroretinogram (PERG) recordings taken before and at multiple timepoints up to two months after exposure to measure the amplitudes of p1, n1, and n2, which represent the different response components from the inner RGC layer. Preliminary results suggest that the vulnerability of RGCs to high-intensity blue

light depends on age, with adults showing greater short-term functional depression and juveniles demonstrating increased resistance to blue light adverse effects. With continued data collection and analysis, I will discover if these patterns either persist or differ with the low intensity and long duration of exposure conditions.

Abstract Name: Mechanical Design of the Target Ladder for the BL3 Neutron Lifetime Experiment

The goal of the BL3 (Beam Lifetime 3) experiment is to resolve a longstanding discrepancy between measurements of the neutron lifetime using a beam versus trapped neutrons. Better determining the neutron lifetime will better refine our understanding of the fundamental laws of physics, explaining Big Bang Nucleosynthesis and the early evolution of the universe. A central component of the BL3 apparatus is the target ladder, which enables the precise positioning of multiple lithium-6 (Li-6) targets in the neutron beam within the vacuum chamber of the neutron detector. These deposits are crucial for measuring neutron beam intensity by capturing neutrons and producing charged particles that are detected downstream. To meet the necessary constraints we are constructing the target ladder from a combination of stainless steel and aluminum, materials selected for their mechanical strength, vacuum compatibility, and minimal activation under neutron exposure. As we highlight this design process which also includes detailed mechanical modeling, material selection based on thermal and structural properties, and careful consideration of vacuum constraints. The assembly incorporates features that aim to ensure accurate target placement, reduce thermal deformation, and allow consistent transitions between multiple target positions. As we are still in the assembly/testing phase of the parts, this current stage of the project focuses on finalizing mechanical assembly and preparing the ladder system for integration into the full setup that will be used. The work lays a foundation for reducing systematic errors and or uncertainty in neutron flux measurements, contributing to the broader experimental goal of improving neutron lifetime precision. Ultimately, this engineering effort supports advancements in both experimental techniques and the fundamental understanding of particle physics and cosmology. As it is crucial to have this deeper understanding in the project.

Abstract Name: Isolating Environmental Phage Targeting E. coli

Course-based undergraduate research experiences (CUREs) play a critical role in addressing systemic inequalities in academia by providing research opportunities to students who might otherwise be excluded

from traditional, highly competitive, application-based programs. These experiences allow students to engage in authentic scientific inquiry, develop critical thinking skills, and gain hands-on experience that is often inaccessible in the conventional laboratory classroom setting. In this project, we aimed to establish a reliable method in which we can isolate K-12 *Escherichia coli* targeting bacteriophages from environmental and fecal samples. Rochester, MN has two lakes, two reservoirs, eight creeks and one river. Notably, Cascade lake, a popular local swimming site, is frequently closed due to elevated *E. coli* levels, highlighting the relevance of studying local environmental bacteriophages. We intend for phage isolation and extraction to serve as the foundation of a future CURE in which students will have autonomy in authentic scientific inquiry, including hypothesis formation, choosing sample sources, and interpreting results with unknown outcomes within the confines of the laboratory space and time. At UMR, however, faculty have been experiencing a consecutive seven-semester streak of failure with phage extraction following well-known protocols. In this project, we adapted and expanded a methodology developed by Dr. Sabrina Green, using a phage-specific buffer and filtration to separate phages from their host bacteria. We then performed a double agar assay to visualize resulting plaques. Using this filtration-based approach, we consistently succeeded in isolating and observing bacteriophages from soil and fecal samples. We also successfully recultivated and diluted emergent phages for continued use in future studies.

Abstract Name: Socioeconomic Inequality and Health Disparities among People Living with HIV/AIDS in China: Assessing the Impact of Urban-Rural Divides and Wealth Stratification on Clinical and Mental Health Outcomes

Socioeconomic inequality presents a barrier to robust HIV/AIDS treatment in China, particularly for individuals living in low income or rural regions. Prior research within this field suggests that distance from healthcare facilities, limited quantity of healthcare resources, and psychological distress can negatively impact engagement in HIV care. Within the field of Public Health, there has been a lack of an updated, concise review that explores how factors such as distance from healthcare facilities, limited healthcare facility resources, and psychological distress can affect clinical and mental health outcomes for people living with HIV (PLWH). I conducted a comprehensive literature review of antiretroviral treatment (ART) access, social determinants of health, and stigma among PLWH in China. Findings from these studies were used to understand the relationship of how urban-rural divides, poverty, food insecurity, and HIV related stigma can contribute to delayed ART initiation, reduced treatment adherence, and worsening mental health. Across multiple studies, PLWH in rural regions experienced significantly longer travel times to HIV healthcare facilities. These healthcare facilities had fewer resources, such as hospital beds, which contributed to lower treatment adherence and uptake. Income instability, such as poverty and unemployment, were strongly associated with a lower quality of life and poor treatment adherence. HIV stigma was also positively correlated with depressive symptoms and suicidal ideation potentially causing disengagement from care. Socioeconomic inequities significantly worsened HIV clinical and mental health outcomes among PLWH in China. Policies such as the Four Frees and One Care and National Free ART Program have expanded access to ART, however, there are still challenges in rural regions. Based on this review, new policies should prioritize convenient travel to rural HIV care clinics and reduce financial costs to improve treatment accessibility and overall well-being among PLWH in China.

Abstract Name: From Local Stages to Global Stories: A Cinematic Exploration of Music, Culture, and an Evolving Global Perspective

This project explores how cultural exchange through music fosters a sense of shared community, centering on my experiences in both local and international settings. Over multiple trips to Japan, I have documented how American music genres, like rock and blues, are embraced and reinterpreted within Japanese culture. By blending on-location research, collaborative filming, and personal reflection, this project highlights how music bridges cultures and expands our understanding of belonging. As I immersed myself in this ongoing journey, working with local musicians and capturing performances in various communities, each step not only contributed to the film but also reshaped my own global mindset. Every encounter revealed how music creates shared spaces of community, helping me grow in confidence and understanding. Ultimately, this project highlights how the experience of creating a cross-cultural film can illuminate the powerful role of music in building connections and transforming our understanding of both local and global communities. It dives into the evolving perspective of a researcher who, through each phase of the project, gains new insights into the universal language of music, the beauty of shared human connection, and the confidence that comes from stepping beyond one's comfort zone.

Abstract Name: The Impacts of Hygiene Disparities on 4-Year University Students

While food insecurity has been widely studied, hygiene poverty remains an overlooked issue. College students across the United States face growing challenges in meeting their basic needs, including access to food and hygiene products. The student researchers examine hygiene poverty at a rural four-year university in Texas, focusing on how limited access to hygiene items affects college students' well-being and success. The following research questions were developed: (1) "How does hygiene poverty impact four-year university students?" and (2) "Is there a distinction between traditional and non-traditional students as it pertains to hygiene?" This descriptive study explores this gap in available resources. Hygiene disparities on college campuses are relevant to the social work profession because it deals with basic needs, self-esteem, dignity, and academic performance. The targeted sample size is 75 traditional and non traditional students who are enrolled at a four year university. A non-probability, convenience, and purposive sampling approach is used to recruit participants in the examination of hygiene needs among university students. Participants are recruited from convenient locations such as the campus pantry, Greek life meetings, and existing campus tabling events. The survey includes 34 questions in total with three sections that include, demographics, hygiene access and affordability, and personal or sensitive experiences.. The feedback from the participants helps identify which hygiene products are most needed and how access to these items influences students' daily lives. The results help the university make improvements to the pantry and develop new hygiene drives and strengthen community partnerships to make sure that access to hygiene products stays consistent. Additionally, the knowledge gained from this study contributes to social work research by highlighting the importance of addressing hygiene poverty as a critical component of student support and overall success.

Abstract Name: Microplastics in Philadelphia's Grey Squirrels (*Sciurus carolinensis*) and Canada Geese (*Branta canadensis*)

Microplastics (MPs, < 5 mm) are ubiquitous in the environment and bioaccumulate in organisms when unintentionally ingested or mistaken for food. To assess the pervasiveness of MPs in Philadelphia's wildlife, fecal samples were collected from grey squirrels (*Sciurus carolinensis*) and Canada geese (*Branta canadensis*) that were brought to the Wildlife Clinic at The Schuylkill Center for Environmental Education. The date and location where the individual was found and its approximate age were recorded with each sample. Fecal samples from sixteen squirrels and thirteen geese were collected by clinic staff. In the laboratory, samples were examined for MPs by sieving, density separation, and spectroscopy. We found an average of 27 MPs per squirrel and 117 MPs per goose, with average concentrations of 667 ± 648 and 603 ± 309 MPs per gram of feces, respectively. No correlations were found between MPs and age or location, suggesting an even distribution of MPs throughout Philadelphia. The overlap in concentrations of MPs between both species suggests they are being equally exposed to MPs, and that MPs are present in most places these animals inhabit. This is concerning because these species do not have similar diets and demonstrates that MPs are likely in several levels of the regional food web. As mammals, MPs in grey squirrels may indicate MPs found in humans, children, and/or pets that play outside. As a semi-aquatic migratory species, Canada geese may act as a vector of MPs among regions.

Abstract Name: Artificial Night and Effects on Ecosystems

Artificial light at night (ALAN) is a growing source of skyglow that degrades astronomical observations, and has significant broader impacts on public health and ecology around the area. This research measures the ALAN around the campus of Minnesota State University, Mankato and the observatories on campus. Across two nights of observation, we assessed ALAN on campus at around 90 unique locations; these data have been extended with additional measurements from introductory astronomy students. We used an Opble Light Master device to measure the illuminance (lux), the correlated color temperature (CCT), shielding quality, and flicker state of each light. We measured illuminance levels between 14-161 lux, CCT were consistently high, falling between 3570-4075 K, characteristics of cool-white LEDs known to contribute strongly to Rayleigh scattering and skyglow. Photometric flicker data showed mostly "no risk", but with intermittent high risk spikes concentrated near specific posts. This indicated inconsistent LED driver performance which can further produce migraines in people and negatively affect their sleep schedule. This data provides a quantitative baseline for understanding how campus lighting contributes to ALAN and supports future recommendations for adopting warmer-cooler, lower-intensity, and flicker stable lighting solutions to reduce environmental and astronomical impacts.

Abstract Name: Investigating Cardiomyocyte Mitophagy Dynamics in the Left Ventricle of the Mouse Heart Following Transverse Aortic Constriction

Cardiovascular diseases are the leading cause of death globally, with mitochondrial dysfunction being a key feature of their pathogenesis. Mitochondria are vital for converting fuel (e.g. fatty acids and glucose) into ATP within the heart to support cellular function and blood flow to the body. When damaged, mitochondria undergo a lysosomal-mediated degradation process known as mitophagy to prevent further accumulation of reactive oxygen species which can further modify cellular proteins and lipids and exacerbate damage. Cardiomyocytes are primary cells of the heart that play an important role in cardiac contractile function. In this study, we used the mito-QC mouse model which expresses a dual fluorescent mitochondrial targeted fusion protein mCherry-GFP, which exhibits both green and red fluorescent signals in the mitochondria under basal conditions, but will fluoresce only red when undergoing mitophagy due to the acidic lysosomal environment. This allows us to visualize mitophagy under fluorescent microscopy. Using the desmin antibody which specifically stains cardiomyocytes, we investigated whether there are changes in mitophagy activity within cardiomyocytes in the left ventricle of the mouse heart following transverse aortic constriction (TAC) compared to sham-operated controls in both male and female mito-QC reporter mice. At 4 days post TAC, we found an increase in overall mitophagy activity, with males having higher levels of mitophagy activity compared to females, which are mostly attributed to an increase in mitophagy activity within cardiomyocytes of the left ventricle following TAC.

Abstract Name: Beyond the Baseline: A Comparative Analysis of Vision-Language Models and ResNet50 for Few-Shot and Full-Data Cancer Classification

Accurate classification of medical images is a critical task in oncology, but it often relies on large, manually annotated datasets. While deep learning models like ResNet50 are the standard, they traditionally require this “big data.” This research investigates the performance of Vision-Language Models (VLMs) as a powerful alternative, particularly in data-scarce scenarios. We conducted a rigorous comparative study of a fine-tuned ResNet50 baseline against a VLM (CLIP) on two distinct medical imaging modalities: a binary breast cancer

histopathology dataset and the 7-class HAM10000 dermatoscopy (skin cancer) dataset. We evaluated both architectures across three paradigms: (1) zero-shot classification (VLM only), (2) 10-shot learning, and (3) full-dataset training, measuring accuracy, weighted F1-Score, and AUC-ROC. Our results reveal a nuanced performance landscape. In the zero-shot setting, the VLM's performance was modality-dependent: it failed on abstract histopathology images (0.41 AUC) but demonstrated baseline capability on photo-like skin lesions (0.62 AUC). The few-shot (10-shot) comparison yielded a critical finding: ResNet50 outperformed the VLM on the abstract histopathology data (0.706 vs. 0.648 F1-Score), while the VLM outperformed ResNet50 on the "real-world" photo dataset (0.558 vs. 0.518 F1-Score). Most significantly, in the full-data setting, a VLM linear probe (training only a final classifier head) consistently outperformed the fully fine-tuned ResNet50 on both datasets, achieving a higher AUC-ROC on both breast (0.940 vs. 0.931) and skin (0.944 vs. 0.917) cancer. This study demonstrates that the pre-trained feature space of VLMs is exceptionally robust, capable of outperforming traditional CNNs even with significantly less training. Furthermore, our findings suggest the optimal few-shot learner is data-dependent: ResNet50's ImageNet features may be superior for abstract patterns, while a VLM's web-scale features are more effective for photo-realistic medical images.

Abstract Name: Extracellular Vesicles Provide a Real-Time Recording of Intracellular Signaling: EGFR receptor presence and implications for personalized therapy

Breast cancer is a leading cause of cancer-related deaths worldwide. While current treatments target specific cell-surface receptors and improve outcomes, the disease's aggressiveness stems from abnormal signaling pathways that drive uncontrolled growth and survival. The epidermal growth factor receptor (EGFR) family, particularly EGFR and HER2, plays a critical role in cell signaling related to proliferation, survival, and progression of breast cancer. To better understand the causes of cancer aggressiveness, the extracellular signaling activity of EGFR was investigated in triple-negative breast cancer (TNBC) 4T1 cells, which, despite their classification, display wild-type EGFR and HER2 receptors similar to double-positive MDA-MB-361 cancer cells. Phosphorylation of cytoplasmic regions of EGFR and HER2 strongly correlate with patient susceptibility to anti-HER therapy. HER2 and EGFR signaling at the cell surface is followed by movement of the receptor complex into endosomes. It is unclear whether these endosomes become extracellular vesicles (EVs) that reflect the internal signaling events of the cells that release them. EVs may offer a way to eavesdrop on the ongoing internal signaling activity of the HER family receptors and could potentially be used to individualize therapy. 4T1 and MDA-MB-361 cells were treated with EGF, then EV isolation was performed through centrifugation, and remaining cells were lysed. EVs were purified using IZON columns before Western Blot analysis. Phosphorylation of EGFR (Y1068) and HER2 (Y877) was measured at different times after ligand stimulation and compared to the EVs released by the same cells. p-EGFR was clearly elevated in the EVs in a dose- and time-dependent manner. These results suggest that the phosphorylated state of HER family receptors in EVs can reflect internal signaling. This finding has clinical implications and may help guide future personalized therapies using EVs from tumor biopsies or blood samples

Abstract Name: Evolving Trends in Organ Donation, Recovery, and Utilization in the United States: A Decade of Change and the Impact of COVID-19

Background: Over the past decade, organ donation and transplantation in the U.S. have undergone substantial changes, influenced by evolving donor practices and the COVID-19 pandemic. We examined national trends in donor types, organ recovery, utilization, and discard rates between 2012 and 2023. **Methods:** We analyzed SRTR/OPTN registry from 2012–2023, including total deaths, DBD (donation after brain death); DCD (donation after circulatory death); NRP (normothermic regional perfusion), organ authorization, recovery, transplantation, and discard rates. Pre-COVID (2016–2019) was compared with post-COVID (2020–2023). **Results:** A total of 259,544 deaths and 134,625 DD were analyzed. DD increased by 100.6% and DD per death by 52.7%. DBD remained predominant (76.5%), but DCD donors increased markedly—especially DCD with NRP (+1496.3%). Organ authorizations, recoveries, and transplants rose 106.3%, 97.4%, and 76.1%, respectively. Post-COVID, donations, recoveries, and transplants increased significantly, but organ recovery and transplant efficiency ratios declined. Kidneys and livers remained the most commonly recovered and transplanted organs. Average organs transplanted per donor declined post-COVID (2.75 vs. 3.05, $p=0.009$), with decreases across most organs, particularly pancreas, liver, heart, and lung. DCD with NRP donors showed increased yield, while DBD and DCD without NRP declined. Discard rates rose for most organs, with pancreas and kidney having the highest. **Conclusion:** Despite substantial increases in donor numbers and organ availability, organ utilization efficiency has declined post-COVID. The rapid growth of DCD, particularly with NRP, represents a critical opportunity for expanding the donor pool. Efforts to reduce discard rates and improve utilization efficiency will be essential to maximize transplant benefit in the coming decade.

Abstract Name: Nucleic Acid Nanoparticles in Immunological Design and Therapeutic Development

Nucleic acids can be engineered to self-assemble into nucleic acid nanoparticles (NANPs), offering a programmable platform for immunomodulation, therapeutic delivery, and disease-relevant intervention. The Afonin Lab is actively developing NANPs with tunable biological behavior to address clinical challenges in infection, cancer, cardiovascular disease, and drug safety. Our ongoing work investigates how NANP sequence, architecture, and physicochemical properties shape immune recognition and cytokine output. Recent studies in the lab demonstrate that immune response can be predicted directly from NANP sequence using transformer-based deep-learning models capable of forecasting IFN- β and IL-6 levels with high accuracy. In parallel, we examine how composition and delivery vehicles, including PAMAM dendrimers and lipid carriers, influence cellular uptake and subsequent activation of immune signaling pathways such as RIG-I, IRF, NF- κ B, and cGAS-STING. Structural format is also a critical variable; DNA- and RNA-based fibers, cubes, and condensates display distinct immune profiles, and aptamer functionalization can suppress or enhance interferon responses depending on scaffold accessibility. Translational relevance is highlighted by current work showing that NANPs augment type-I interferon responses in *Staphylococcus aureus*-infected osteoblasts and osteoclasts, reducing bacterial survival and demonstrating potential as immunostimulatory adjuncts for persistent infections. Collectively, our research advances the design of nucleic acid nanostructures as customizable immunomodulatory tools. By controlling topology and sequence, we aim to

develop next-generation NANP-based platforms for therapeutic delivery, antimicrobial defense, and immune engineering. The purpose of this presentation is to synthesize current evidence on how NANPs interface with the immune system, with particular focus on the determinants of immune recognition, activation, and therapeutic modulation. By reviewing current studies in nucleic acid nanotechnology, including studies on AI-guided immune prediction, structural drivers of immunostimulation, backbone modifications, dendrimer delivery platforms, and biomedical applications, we aim to identify shared mechanisms, emerging strategies, and remaining knowledge gaps.

Abstract Name: Interventions and outcomes of service-learning in undergraduate STEM classrooms: a scoping review

Service-learning is a pedagogical practice that allows students to engage with outside communities while learning course content. Students in service-learning courses gain a better understanding of the material, develop problem-solving skills, and experience improved motivation. While there are several benefits of service-learning, there is a lack of literature to guide the development of STEM service-learning courses. We are using guidelines from the Joanna Briggs Institute and Prisma extension for scoping reviews to characterize STEM service-learning. The research is guided by the following questions: 1) How have instructors implemented service-learning in undergraduate STEM environments, and 2) What outcomes do students experience by participating? Primary research and review articles on service-learning in STEM undergraduate classrooms within U.S institutions were included in the review. Articles (n = 8,111) were identified from the PUBMED, SCOPUS, and EBSCO databases, and duplicates (n = 3,489) were removed. In the first-round screening, we analyzed titles, abstracts, and key words, and removed articles that did not fit our inclusion criteria (n = 4,208). We are currently doing a full-text screening of the remaining articles (n = 414). Approximately 50% of the remaining articles have been screened by at least one researcher. Engineering (22%), Biology (13%), and Environmental Science (9%) are best represented within the dataset. The next step of the research will involve qualitative coding to discover common themes among the articles. Results from this study will be used to describe best practices for STEM service-learning and to aid in the development of novel service-learning programs in STEM.

Abstract Name: Quantifying Banana bunchy top viral components to understand how Wolbachia endosymbiont impacts virus transmission

Banana bunchy top virus (BBTV), a multipartite single-stranded DNA virus, is a devastating pathogen of

bananas worldwide and is transmitted in a persistent, circulative, non-propagative manner by the aphid *Pentalonia nigronervosa*. The bacterial endosymbiont *Wolbachia pipientis* is known to reduce BBTv transmission in its aphid host, but the mechanism has remained unknown, particularly since the virus does not replicate in the vector. This study investigated the hypothesis that *Wolbachia* interferes with BBTv by altering the accumulation of its genomic components within the aphid. *Wolbachia*-positive and *Wolbachia*-negative aphids were allowed to acquire BBTv from infected plants over varying time periods. Quantitative PCR was used to measure the accumulation of all six BBTv genomic components (DNA-R, -S, -C, -N, -U3, -M). The results demonstrated that *Wolbachia* infection significantly modulates viral component accumulation. Notably, DNA-S, which encodes the viral capsid protein (CP), consistently accumulated to lower levels in *Wolbachia*-positive aphids. In contrast, the accumulation of other components, such as DNA-R and DNA-C, was often higher in the presence of *Wolbachia*. The specific suppression of the capsid protein component suggests a targeted interference mechanism, where a deficit in CP could compromise virion assembly and stability, thereby impeding the successful circulative transmission of BBTv. These findings reveal a novel function for *Wolbachia*, expanding its role beyond blocking replicative viruses to include disrupting non-propagative, circulative transmission, with significant implications for developing symbiont-based strategies for managing plant viral diseases.

Abstract Name: Discharging From a Distance with a Van de Graaf “antenna”.

While working with a Van de Graaf (VdG) generator, we observed a phenomenon not normally listed for electrostatic demonstrations: By using a simple “antenna” with the VdG, one can neutralize a charged object located two or more meters away, with no interconnecting conductor. We here report on (1) Distance-discharging both a charged pom-pom and another charged VdG; (2) Reversing the polarity of the VdG and charged object, and comparing time-to-neutralize for negative versus positive corona, and (3) using an electric field mill to detect the “ion wind” (a.k.a. “electric wind”) emitted by the antenna.

Abstract Name: Interplanetary drivers of major geomagnetic storms.

The importance of studying geomagnetic storms and their solar drivers has been recognized as a fundamental concern and a central part of geophysics for decades. In short, a geomagnetic storm is a major disturbance of Earth's magnetosphere and constitutes the most important component of space weather effects on Earth. It is widely accepted that the coupling dynamics between disturbances in the solar wind and the Earth's magnetosphere is the main cause of geomagnetic storms. Interplanetary coronal mass ejections (ICMEs) and high-speed solar wind streams (HSS) from corotating interaction regions (CIRs) are the main sources of such

disturbances in the solar wind. By a superposed epoch analysis, this work is focused on validating the coupling dynamics between the solar agent and the Earth's magnetosphere by characterizing the perturbation in the solar wind causing some major geomagnetic storms. The used index for selecting major geomagnetic storms was the well-known Dst index: all cases under this study were classified as severe or extreme geomagnetic storms with $Dst \leq -200$ nT. In the case of the solar wind, we used the magnetic field, ion temperature, the β -plasma, and the flow speed.

Abstract Name: Political, Economic, and Social Forces Behind the Post-2008 Rise of Populism and Its Influence on Democratic Governance

Since the 2008 global financial crisis, many developed countries have experienced a pronounced rise in populist and nationalist movements, yet the specific political, economic, and social dynamics driving this shift remain contested. This project investigates why these movements have gained traction across democracies and examines how they have subsequently shaped electoral outcomes and policy decisions. The research is motivated by the need to understand how long-term economic insecurity, political distrust, and social polarization interact to reshape democratic norms and political behavior. To address this question, the study draws on a mixed qualitative and historical methodology, combining surveys, interviews, and systematic analysis of political speeches with a comparative review of major political events since 2008. Surveys and interviews capture citizens' perceptions of economic inequality, cultural identity, and institutional legitimacy, while the textual analysis of speeches allows for identifying recurring rhetorical strategies, emotional appeals, and narratives used by populist leaders. Historical and comparative analysis provides a broader lens through which to track how crises, austerity measures, and shifting social conditions influenced the appeal of these movements over time. Preliminary findings suggest that economic displacement, perceived cultural threat, and declining trust in political institutions converge to create openings for populist actors who promise restoration, protection, or profound institutional change. These movements have influenced elections by mobilizing previously disengaged voters and reshaping party coalitions, while their policy effects include stricter immigration measures, challenges to international cooperation, and reforms aimed at centralizing executive power. Understanding these dynamics contributes to broader conversations about democratic resilience and offers insight into how governments, civil society, and voters might respond to continued populist influence in future political cycles.

Abstract Name: Using Machine Learning to Predict RISM 1D Equations

Our research aims to find a faster way to model liquids using the reference interaction site model (RISM) of molecular solvation. This application uses a statistical-mechanical method to compute different functions, such as the radial distribution function and the thermodynamics of a liquid, which uses hard to solve equations taking longer computation time. Our solution to this problem is to train a neural network to

approximate the outcomes for said RISM equations, providing better estimates for more complicated solutions. By collecting and storing data ran from RISM, the neural network uses it to train and predict solved equations of RISM, thus providing a faster way to calculate interactions between the solute and solvent within a solution. The neural network is then used to predict more complex solvents/cosolvents instead of water, like salts (sodium chloride) and ethanol at different densities and temperatures at which it uses the potential energy function to predict these RISM solutions. This may in turn help the time for computation of these equations and provide how different solvents and solutes interact, especially at higher concentrations giving better predictability in wet labs.

Abstract Name: ARISE: Real-Time Multi-Modal AI for Senior Wellness on Edge Devices

The global rise in the aging population presents growing challenges for maintaining physical activity, rehabilitation, and independent living. While digital exercise tools have emerged, many fail to balance performance, privacy, and accessibility—particularly for older adults using low-power devices. This paper introduces ARISE, a multi-modal, privacy-preserving AI system that integrates human pose estimation and conversational interaction to create an engaging at-home exercise experience. Implemented entirely on the network edge, ARISE leverages the Raspberry Pi 5 and Hailo-8 Neural Processing Unit (NPU) to achieve real-time, on-device computation without reliance on cloud services. The system combines a YOLOv8m-Pose model for body tracking with a voice-based conversational pipeline using Vosk (speech-to-text), LLaMA (language model), and Kokoro-TTS (speech synthesis) for natural feedback and guidance. Experimental results demonstrate significant reductions in inference latency with NPU acceleration and optimized conversational responsiveness through adaptive chunking and segmentation strategies.

Abstract Name: Empowerment Through Education: Developing an Accessible Sexual Health Curriculum

This project focuses on the development of a comprehensive and accessible sex education program tailored for college students with intellectual disabilities. The study aims to increase sexual health literacy, relationship skills, and self-advocacy in young adults with intellectual disabilities through a peer mentoring

model. The design reflects recent research using peer mentor approaches, and accessible education (McGrath et al., 2025; Nelson et al., 2025). Previous research suggests that people with intellectual disabilities benefit from sexual education that is relatable, empowering, and uses real experiences. Peer educators are helpful in reducing stigma, increasing engagement and information retention (James et al., 2022; Toman et al., 2024). In recognizing the limited availability of developmentally appropriate sexual health resources for this population, this project designed a comprehensive and accessible four-week curriculum using plain language, visual aids, interactive activities, and repetition to strengthen understanding and engagement. This project aims to design and test a curriculum that teaches sexual health and related topics in a relevant, respectful, and developmentally appropriate way for the community it serves. We plan analysis the curriculum using a mixed-methods approach with pre/post survey and interview data. Our population includes young adults over 18 enrolled in the EXCEL program at Bridgewater State University that present with approximately 70 or below IQ score and are eligible for special education in Massachusetts. Ultimately, our goal is to expand access to equitable sexual health education, promote healthier relationships, and support a more empowered and inclusive environment for adults with intellectual disabilities.

Abstract Name: Social Media Use, Perfectionism, and Gender as Predictors of Body Dissatisfaction

Body dissatisfaction is an increasingly prevalent concern among college students, and prior research has shown the devastating implications of body dissatisfaction, particularly its role in the development, maintenance, and relapse of eating disorders. These factors can lead to overall negative outcomes such as anorexia nervosa, low-self esteem, depression, or cosmetic surgery. Social media use, perfectionism, and gender have long been shown to correlate with body dissatisfaction and disordered eating. Gender, for instance, is a significant factor in the development of body dissatisfaction, eating disorders, and mental health issues, often due to societal pressure to conform to gendered expectations. Consequently, this study examined whether rigid, self-critical, and narcissistic perfectionism, as well as social media use and gender, would predict body appreciation, using a sample of 139 (85 females; 53 males; 1 “Other”) undergraduate students. Materials included the Big Three Perfectionism Scale-Short Form (BTPS-SF), the Social Media Use Scale (SMUS), and the Body Appreciation Scale-2 (BAS-2). To analyze the data, a multiple linear regression study was used to establish results. Results showed that many of the anticipated relationships were significant, including the following predictors of body appreciation: self-critical perfectionism, social media use, and gender. However, rigid and narcissistic perfectionism did not predict body appreciation. These findings suggest that external social pressures, personality traits, and gender are associated with body dissatisfaction and demonstrate the importance of utilizing multifaceted models of personality in the study of body image. Further implications of these findings are discussed and directions for future research are posited.

Abstract Name: Effect of Ocean Acidification on Shell Dissolution of the Pteropod *Clio pyramidata* from the

Gulf of Mexico

Rising atmospheric carbon dioxide is reducing the pH and calcium carbonate concentrations in our oceans. The average ocean pH is currently ~ 8.01 and is estimated to drop to ~ 7.78 by the year 2100. Organisms that rely on calcium carbonate to build their shells or skeletons, such as corals, coccolithophores, and some sea snails, would be some of the first organisms affected by these shifts in ocean chemistry. Pteropods, an open water sea snail, are especially vulnerable since their shells are made from aragonite, which is more easily dissolved. This study aims to evaluate how the projected 2100 ocean conditions could affect the pteropod *Clio pyramidata* from the Gulf of Mexico. Shells from nonliving organisms will be exposed to low pH, and the level of shell dissolution will be quantified by measuring shell thickness and external corrosion of shells. Past studies have mostly focused on the Arctic species *Limacina helicina* and little is known about the effects of ocean acidification on other species. *Clio pyramidata* has a much thinner and elongated shell than *L. helicina* and the results from this study could help determine whether different species and shell morphologies are more vulnerable to ocean acidification.

Abstract Name: Cyclopropanation Catalysis Via *Shewanella oneidensis*

Cyclopropanes are integral to many pharmaceutical products, but due to their high ring strain, synthesis often requires dangerous conditions. *Shewanella oneidensis* is an electroactive facultative anaerobe with a metal respiratory pathway and the ability to facilitate synthetic transformations via extracellular electron transfer (EET), making it a potential biocatalyst for compounds like cyclopropanes. By investigating the biocatalytic abilities of *S. oneidensis*, we worked to determine if *S. oneidensis* could respire using cyclopropanation products and whether the concentration of these products affected cell survival. Using biological and chemical techniques, including cell culturing and colony counting, results showed an average increase of colony forming units (CFU) in wild-type *S. oneidensis* as cyclopropanation product concentration in growth media was raised and a decrease in CFU in mutant bacteria. Using whole cell biocatalysis, and analysis via gas chromatography-mass spectrometry, we investigated how cyclopropanation ability was affected by different EET genetic knockout strains of the bacteria. We observed significantly decreased cyclopropanation product yield in knockout strains as compared to the wild-type. These results suggest that *S. oneidensis* may depend on the metal respiratory pathway to utilize cyclopropanation products. There also may be some concentration dependence, as higher concentrations of these compounds are associated with higher cell survival in wild-type bacteria. EET knockout strains seem to also have lessened cyclopropanation ability. With further refinement of experimental procedure and larger sample sizes, the genes responsible for cyclopropanation could be further narrowed down and the rate of synthesis could be placed under genetic control for a broad range of biochemical applications.

Abstract Name: Generations Apart: The Impact of Puerto Rican Residency in the United States on Identity and Perceptions of Latinidad

Puerto Rico, home to some of the greatest talents in music and athletics, with its rich history, culture, and people. However, behind the beauty of the archipelago lies a story of displacement, resilience, and colonization. Puerto Rico remains a colony of the United States and the oldest colony in the world. This colonial status creates a unique relationship in terms of migration, as Puerto Ricans have been granted U.S. citizenship since the Jones-Shafroth Act of 1917. Over 5.9 million Puerto Ricans reside in the United States, while over 3.2 million people reside in Puerto Rico, thus making those in the diaspora outnumber those who remain in the archipelago. In my research, I ask how does the generational distance and displacement from Puerto Rico shape Puerto Rican self-identification and (pan)ethnic identity? Using a qualitative approach, I conducted one-to-two-hour long, one-on-one interviews, both in person and over Zoom. I interviewed over forty individuals who identify as Puerto Rican. Within this sample, I interviewed people who identify as currently living in the archipelago, those who are in transit and travel between the U.S. and Puerto Rico, first-generation Puerto Ricans in the United States, second-generation, and third-generation and beyond. Puerto Rican migration to the U.S reshapes Puerto Ricans' understanding of belonging, nationhood, and racial/ethnic identity. Through my research, I have discovered that leaving the archipelago, no matter what generation they have left, comes with uncertainty and internal/external measurement of authenticity to one's Puerto Rican identity. The displacement of the island has caused Puerto Ricans to question how Puerto Rican they are, which then in turn affects the actions taken towards strides to anticolonial practices, cultural maintenance, and political behavior. Puerto Rican identity has become multisite and negotiated, not limited to birthplace, thus contributing to a transnational Puerto Rican nationhood.

Abstract Name: Title: Triptolide and Organelle Stress: Unlocking New Paths in Cancer Therapy

Background: Triple-negative breast cancer (TNBC) remains one of the most aggressive subtypes of breast cancer, lacking effective targeted therapies. Triptolide, a bioactive compound derived from *Tripterygium wilfordii*, exhibits potent anti-cancer properties in malignant cells. However, its impact on non-cancerous human mammary epithelial cells (HMECs) and the mechanisms underlying organelle-specific stress responses remain poorly understood. Objective: This project seeks to elucidate whether triptolide induces stress in critical organelles—nucleus, lysosomes, and mitochondria—in HMECs and to determine how these changes may activate cell death pathways. Understanding these mechanisms is essential for evaluating triptolide's therapeutic index and minimizing off-target toxicity. Methods: HMECs will be cultured and treated with graded concentrations of triptolide. Organelle integrity will be assessed using fluorescent markers: DAPI for nuclear morphology, LysoTracker Green for lysosomal activity, and Mitotracker Green for mitochondrial function. Fluorescence microscopy will be employed to visualize chromatin condensation, lysosomal membrane stability, and mitochondrial potential. Significance: By clarifying triptolide's effects on non-cancerous cells, this research contributes to the development of safer, lysosome-targeted cancer therapies and underscores the potential of natural compounds in overcoming chemotherapy resistance. Student Impact: Conducted by a Hispanic undergraduate at a Hispanic-Serving Institution, this project exemplifies inclusive research practices and mentorship that advance diversity in STEM and prepare students for graduate-level biomedical research.

Abstract Name: Exploring Temperature Acclimation in Brook Trout White Muscle from qPCR Analysis

Climate change is steadily progressing, leading to elevated water temperatures in aquatic systems. Such thermal increases often result in biological stress as energy budgets are disrupted. Brook trout are predicted to experience a significant climate-driven decline in the upcoming decades as their habitats will continue to warm. Thermal acclimation is a key mechanism that may mitigate some of the impact a changing climate can have. Acclimation to warm water leads to a reduction in resting metabolic rate in brook trout. In this study, we examined how shifts in temperature influence gene expression in brook trout white muscle. Gene expression levels were quantified via qPCR for a selection of gene targets following reverse transcription of RNA extracted from the white muscle tissue. Our findings indicate that acclimation to elevated temperatures induces measurable changes in brook trout gene expression. Warmer conditions are associated with shifts in genes associated with metabolism and an overexpression of stress related genes. These results are consistent with an acclimation response that may mitigate some of the impact of climate change but also reflect an increase in biological stress when the fish encounter higher water temperatures.

Abstract Name: Examining the role of MAP3K4 and HDAC6 on fetal and placental growth in the 129/SvEv background

Fetal growth restriction (FGR) affects up to 10% of human pregnancies worldwide. FGR is a risk factor for multiple disease states in adulthood, including cardiovascular disease and diabetes. Placental dysfunction is one of the principal causes of FGR. Recently, our lab demonstrated that an enzyme called mitogen-activated protein kinase kinase kinase 4 (MAP3K4) has a critical role in embryonic and placental growth in mice. MAP3K4 kinase inactive mice (Map3k4KI/KI) also have reduced survival at weaning age, representing 6% of the total population. The few Map3k4KI/K mice that survived were significantly smaller than wild-type mice, a hallmark of FGR. We also demonstrated that the enzyme histone deacetylase 6 (HDAC6) is hyperactive and overexpressed in Map3k4KI/KI trophoblast stem cells that differentiate into the major cell types of the placenta. However, a role for HDAC6 in normal placental development is unknown. The goal of this project was to test the hypothesis that hyperactive HDAC6 has a role in the lethality and growth restriction phenotype of Map3k4KI/KI mice. To test this hypothesis, we genetically deleted Hdac6 from Map3k4KI/KI mice through a breeding strategy with a commercially available Hdac6 knockout strain from Jackson Laboratory. Using the mice gained from this line, we then bred them and dissected each conceptus from pregnant mice 13.5 days post plug confirmation. These were then imaged, the placentas weighed, and the embryos were genotyped. Our results suggest that deletion of Hdac6 improved midgestational growth of Map3k4KI/KI embryos and placentas. Collectively, our findings demonstrate a previously unidentified role for HDAC6 in embryonic and placental growth in mice.

Abstract Name: Refusal and the Aesthetic Origins of Political Thought

Political thought rarely emerges from formal theory alone. Instead, political consciousness often arises from the images, emotions, and cultural encounters that make power visible before individuals ever engage with canonical texts. Traditional approaches tend to present political theory as something grounded in rational argument and normative principles, yet these frameworks overlook the experiential and imaginative beginnings of political understanding. Drawing on philosophy, political philosophy, and culture and media studies, this project examines how the idea of aesthetics, in the sense developed by Rancière and later taken up by Foucault, creates the conditions in which political thought becomes possible. Aesthetic and narrative experiences shape perception, reveal structures of domination, and prompt early recognition of injustice. These beginnings also resonate with Bonnie Honig's work in *A Feminist Theory of Refusal*, which argues that acts of withdrawal, disruption, and refusal open space for political awareness and challenge established power. The project uses these frameworks to explore the broader claim that political understanding is grounded in encounters that precede formal theory. By focusing on how individuals come to sense, interpret, and respond to power through aesthetic and affective experience, the project reframes the origins of political thought and highlights the importance of perception in the formation of political consciousness. This approach positions aesthetics not as an accessory to political theory but as one of its foundational conditions. By tracing these early pathways into political thinking, the project reevaluates what political theory is, how it forms, and why people continue to rebuild and reinterpret it. The aim is to imagine guidelines for political theory that encourage exploration rather than restriction and that recognize the diverse routes through which political consciousness develops.

Abstract Name: Sisterhood Across Seas: Pan-Africanism and International Women's Anti-Apartheid Networks during the 1970s-1980s

In 1900, the first Pan-African Conference was held, marking the beginning of a new movement in support of a free Africa. Now the movement is worldwide, continuing the fight for a free Africa from colonizers and their impacts. Yet, scholarship underscores the prominent role of men like Henry Sylvester Williams and Kwame Nkrumah but tends to overlook women's contributions. This paper seeks to shed light on women's contributions to Pan-Africanism through the study of the international women's anti-apartheid campaign in the US and Europe. The research uses a qualitative analysis of primary sources from three key archives: Forward to Freedom (UK), African Activist Archive (US), and The Freedom Archives (US). These documents include conference minutes, mailings, leaflets, and programs from groups like the Anti-Apartheid Movement Women's Committee and the South African Women's Fund. These resistance groups employed strategies such as fundraising for aid, spreading awareness with talks from exiled South African women, and more. The actions of these groups are examples of Pan-Africanism in the fight within the international Anti-Apartheid movement in the 1970'-1980's. This paper thus demonstrates that these international solidarity networks in support of women in South Africa under Apartheid embodied Pan-African ideals despite the lack of scholarship on women in the Pan-Africanist movement. The women's international anti-apartheid movement of the 1970s-1980s embodied Pan-Africanist ideals and theory. The Pan-African ideal connected the struggle in South Africa with people of African descent worldwide, inspiring global solidarity movements. These

movements applied immense international pressure, leading to boycotts, sanctions, and divestment campaigns that were critical in dismantling apartheid-based laws. This connection transformed the anti-apartheid movement into a global struggle for liberation and self-determination for women everywhere.

Abstract Name: The absence of ETA on dendritic cells reduces immune activation and protects against obesity-induced kidney injury

Background: Endothelin-1 (ET-1) is a potent vasoactive peptide elevated in obesity that promotes inflammation via the ETA receptor. Immune cells from the innate and adaptive arms express receptors for ET-1; however, the role that the ET-1/ETA axis in dendritic cells (DCs) plays in obesity-induced kidney damage and metabolic dysfunction remains unclear. Hypotheses: We hypothesized that the absence of ETA on DCs reduces immune activation and improves metabolic function, thereby protecting against obesity-induced kidney inflammation and damage. Because important sex differences exist in the immune response to obesity, we also hypothesized that there will be a greater protection in males than females lacking DC ETA. Methods: DC-specific ETA knockout (DC ETA KO) and floxed ETA control mice were fed a high-fat diet (HFD, 45% Kcal) for 25 weeks. We assessed metabolic function (glucose and insulin tolerance tests), renal injury (proteinuria), kidney T cell infiltration, and physiological characteristics (QMR, water/urine output). Normal-fat diet (NFD, 10% Kcal) mice were used as controls. Results: In response to a HFD, male DC ETA KO showed significantly improved glucose tolerance and insulin sensitivity ($p < 0.001$, $p < 0.01$) demonstrating protection from cardiometabolic stress. Kidney CD3⁺ T cell infiltration was reduced in DC ETA KO mice ($p < 0.05$), consistent with lower immune activation. Female DC ETA KO had reduced proteinuria at early time points ($p < 0.05$), though differences were not sustained at 25 weeks. QMR, body weight, and fluid balance showed no genotype-dependent differences in neither sex. Conclusion/Broader Impact: These findings support a role for DC-specific ET-1/ETA signaling in obesity-driven kidney inflammation, with evidence of sex-related differences in metabolic and immune responses.

Abstract Name: Measuring the Mandate: State Enforceability Index for Mandatory Arbitration of Employment Disputes

Mandatory arbitration is a legal term referring to a clause in a contract that requires the parties to resolve disputes through private arbitration rather than the public court system. These clauses have become increasingly common in employment agreements, but the current literature suggests that courts are the best option for employees by most metrics, including the likelihood of winning a dispute. However, if an employee has a mandatory arbitration agreement, how likely are they to be able to challenge that agreement and actually make it to court in different jurisdictions? In short, how likely are different states to enforce mandatory arbitration agreements? To answer this question, an index was created ranking each state from 1 to 7 based on the enforceability of mandatory arbitration agreements in that state, with 1 signifying very low

enforceability and 7 signifying very high enforceability. Higher enforceability meant less likelihood of employees successfully challenging the arbitration clause. To create this index, first, each state's relevant legislation was given a rank in the 1-7 system based on the text of the law itself, and then this number was modified based on relevant case law in the state and decisions and policy statements from relevant administrative agencies such as state labor boards or state boards of alternative dispute resolution. Specifically, case law and administrative policy were ranked between -1.5 and +1.5 depending on whether they moved the overall state legal landscape toward more or less enforceability. Then, the sum of the legislative, court, and administrative rankings was taken to determine the final state ranking. The final index provides insight into the differences between states' enforcement of mandatory arbitration and, hopefully, will provide background for future analysis of differences in state employee satisfaction rates and other economic factors.

Abstract Name: Group A Streptococcus and Potential PANDAS Pathways in Children ages 4-12: Molecular Mimicry and Recurring Neuroinflammation

Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infections (PANDAS) have been observed in school-aged children following Group A Streptococcus (GAS) infection and may be associated with sudden-onset tic disorders and other neuropsychiatric symptoms. This literature review examined whether pathogenic mechanisms of GAS share possible consistencies with established meningeal pathogens, including *Streptococcus pneumoniae* and *Neisseria meningitidis*, in order to explore whether increased prevalence or recurrence of GAS infections may contribute to higher incidence of PANDAS. Evidence from immunological, microbiological, and neuroinflammatory studies suggested that GAS may trigger post-infectious autoimmune responses through molecular mimicry, in which M-protein and carbohydrate antigens potentially cross-react with neuronal targets such as tubulin and dopamine receptors. These autoimmune mechanisms appeared to parallel host-pathogen interactions reported in meningitis, including cytokine-associated blood-brain barrier (BBB) disruption mediated by $\text{TNF-}\alpha$ and IL-6. Comparative findings indicated that although GAS differs from meningitic bacteria in its lack of direct neuroinvasion, it may produce convergent outcomes: cytokine-driven BBB permeability, infiltration of cross-reactive antibodies into the basal ganglia, and subsequent neuroinflammation that may influence motor and behavioral regulation. Studies also suggested that recurrent GAS infections may amplify these immune cascades through repeated antigenic priming, sustaining autoantibody production even after bacterial clearance. Because standard antibiotic treatment may not fully interrupt these autoimmune pathways, the literature emphasized a need for pediatric public health strategies that include early biomarker-based diagnostics, long-term prophylaxis, and enhanced surveillance in at-risk children. Understanding the possible shared immunopathology between GAS and other neuroinflammatory pathogens may help improve diagnostic precision and support prevention efforts aimed at reducing the burden of PANDAS in school-aged populations.

Abstract Name: Survey of the Assemblage of Dung Beetles in Cimarron County, Oklahoma and the Efficacy of Two Dung Types as Bait

Dung beetles (Coleoptera: Scarabaeidae) are coprophagous insects that can be categorized into feeding guilds based on their feeding behavior, including rollers, tunnelers, and dwellers. They provide important ecosystem services to agroecosystems, yet native dung beetle populations are declining due to factors including habitat loss, shifts in food availability caused by domestic animals, and increased competition from introduced non-native dung beetles. Services provided by dung beetles include increased soil percolation and aeration, secondary seed dispersal, nutrient cycling, and pest control. Dung beetles can control pests such as the endoparasitic nematode *Haemonchus contortus*, an important parasite of pronghorn (*Antilocarpa americana*) transmitted by fecal material. Oklahoma's pronghorn population has also suffered declines in recent years. In this study, we sampled beetles in Cimarron County, Oklahoma to determine the species composition of dung beetles and their potential interactions with pronghorn in the Oklahoma Panhandle area. We also examined the potential differences between wildlife and domestic animal dungs in attracting different dung beetle feeding guilds and species. We set up two transects of pitfall traps ($n = 10$ each) and baited the traps with either pronghorn dung or cattle dung. We recorded the arthropods collected in the traps for two days. We compared the abundance and species richness of beetles in our samples using negative binomial generalized linear models. We also compared the species composition of dung beetles between the dung bait treatments. Pronghorn dung attracted a significantly higher abundance of dung beetles, but there was no difference in beetle species richness between the two types of bait. Our results suggest that dung beetles are attracted more to the dung of pronghorn than to the dung of domestic animals.

Abstract Name: Investigation and Recreation of Nazca Pottery Through Coil Building a Tradition Pot

Pottery is one of the oldest artforms. It has been practiced worldwide throughout human history. One culture with particularly unique style and design is the historic Nazca culture from the southern coast of Peru. This era of pottery dates from 200 BCE and 600 CE. Their pottery is defined by its bold shapes, colors, abstracted stylization, and flat imagery. Nazca artwork typically depicted people, animals, and gods. The line work flowed as a constant thick black line. The pieces themselves were used for decoration, rituals, and grave offerings. The shapes of the pottery ranged from cylinders, spheres, and even humanoid figures. These vessels were created using the coil methods. This involved coiling a cylinder of clay around a base and then smoothing the inside and outside with a flat stone or by hand. The next step was to add slip, usually in a white or earthy tone for the base while maroons, light purples, and other bold hues were used for the details. The firing process would involve heating with actual fire. This was an oxidized atmosphere which reacted with the minerals in the pre-fire slip to create the bold colors. The clay type used in this pottery was a basic earthenware known as terracotta. A distinctive characteristic of the creatures portrayed are large staring eyes. The scleras are bright white and large with a small black pupil. Some scholars believe this represents a drug induced state. The pottery of this ancient culture has served as an important historical reference. After my research into this art history I recreated my interpretation of Nazca pottery. I did so by using the Nazca's coil method. I recreated shapes of Nazca pots. I then added decorative slip to the surface in their style with my own fictional gods.

Abstract Name: Identifying Cl⁻ binding sites on System xc⁻.

System xc⁻ is a membrane protein consisting of two subunits: 4F2HC and xCT. The system exchanges intracellular glutamate for extracellular cystine, which is converted to cysteine upon internalization. Within the cell, cysteine is used to synthesize glutathione, an important antioxidant needed to combat oxidative stress. System xc⁻ requires Cl⁻ ions to facilitate this exchange, but the exact role Cl⁻ plays in supporting cystine/glutamate exchange and its site of interaction within xCT are not yet known. The first question I sought to answer was whether Cl⁻ is transported by System xc⁻ into the cell or whether it only facilitates substrate binding. To address this question, I used a cell permeable chloride sensitive dye (diH-MEQ) to measure changes in intracellular Cl⁻ levels upon activation of the transporter. I observed that chloride appears to be imported upon addition of cystine to the extracellular compartment, but I also observed that in the absence of extracellular Cl⁻, System xc⁻ appears to facilitate the leakage of Cl⁻ from the cell. In addition, I have identified putative Cl⁻ binding sites within xCT. The xCT subunit is the only chloride-dependent transporter in the heterodimeric SLC7 family. Therefore, I identified non-conserved amino acid residues within the channel region of the transporter that could potentially interact with Cl⁻. I am currently using specific site-directed mutagenesis to determine whether these sites contribute to Cl⁻ binding. When completed, this project will provide important insight into the structure/function of System xc⁻, a transporter that plays an important role in cellular health.

Abstract Name: Integration Without Accountability: Schengen Accession and Croatia's Pushback Policy toward Bosnia-Herzegovina

This research examines why Croatia's pursuit of Schengen membership between 2015 and 2023 intensified its use of illegal pushbacks of migrants against Bosnia-Herzegovina. While the European Union (EU) promotes integration through enhanced coordination and shared legal frameworks, this integration mechanism can paradoxically incentivize violence at the union's periphery. Croatia's actions represent a critical case: it faced institutional pressure to demonstrate reliable external border enforcement capabilities to satisfy the expectations of belonging to the Schengen zone, yet this pressure conflicted with international asylum law and humanitarian obligations. This study employs a mixed-methods approach, analyzing quantitative evidence of pushback incidents, testimonies from EU Commission staff and border enforcement agencies, and official Croatian policy documents. The research draws on neofunctionalist and intergovernmentalist European integration theories to explain how state sovereignty allows rational actors to prioritize membership credentials over human rights compliance. Findings reveal that Croatia implemented systematic pushback policies, producing 70% of documented Balkan pushbacks and conducting an estimated 22,500 expulsions to

Bosnia between May 2019 and October 2020, to prove the reliability of border security. The EU approved Croatia's Schengen accession in December 2021 despite violations just months earlier, suggesting that harsh enforcement facilitated rather than hindered integration. This research contributes to understanding the structural and normative tensions within EU border governance, revealing how supranational integration pressures can directly drive violence at member state borders while undermining the Union's own human rights commitments.

Abstract Name: Dual Engines of Conservative Policy: Heritage vs. Alec Shared Founders and Divergent Strategies

Since the early 1970s, the Heritage Foundation and the American Legislative Exchange Council (ALEC) have played pivotal roles in shaping public perception and implementing conservative policies across the United States. Founded in 1973 by Joseph Coors, Paul Wyrich, and Edwin Feulner, the Heritage Foundation established itself as a think tank that packages conservative policy ideas into actionable blueprints, such as the Mandate for Leadership, which served as a playbook for Ronald Reagan's presidency. ALEC, cofounded by Weyrich as well, operates by drafting state-level "model bills" in collaboration with corporate members and conservative lawmakers. This study explores how both organizations developed complementary strategies to push conservative agendas. Together, they created a two-tier pipeline that normalized tax cuts, deregulations, education reform, and socially conservative laws across America. Utilizing academic sources, organizational archives, and policy examples, this analysis examines the funding structures, legislative tactics, and ideological messaging that enabled Heritage and ALEC to institutionalize a pro-business, Christian nationalist vision. While effective, their influence raises concerns about the erasure of diverse cultural, sexual, and religious identities from national policymaking.

Abstract Name: Breaking Barriers: Expanding Bilingual and Culturally Competent SLP Services in South Carolina

Despite the growing Spanish-speaking population in the United States, access to equitable speech-language pathology (SLP) care remains limited due to workforce shortages and linguistic barriers. Recent studies (Gross et al., 2023; Rameau et al., 2023; Morton-Jones et al., 2022) highlight the nationwide lack of bilingual and culturally competent SLPs, with particularly limited availability across the southeastern states, including South Carolina. This project examines the shortage of bilingual and culturally competent SLPs and the resulting disparities in treatment for Spanish-speaking clients in South Carolina. Through a review of current research and interviews at local educational programs and community spaces such as Communication Cottage Therapy and local clinics, the study explores how linguistic and cultural mismatches contribute to misdiagnosis, treatment delays, and feelings of ostracization among the Spanish-speaking population. The findings highlight that the lack of bilingual professionals and accessible resources reinforces unequal access

to quality healthcare and distrust in clinical systems. This research aims to identify actionable strategies for expanding bilingual SLP training programs, promoting community outreach, and developing culturally responsive care models. By improving representation and accessibility within the SLP field, the project advocates for a more inclusive approach that recognizes language as a fundamental component of both identity and healthcare equity.

Abstract Name: "Vibrioid" formation in *Vibrio cholerae*

Model pathogen and causative agent of the lethal disease cholera, *Vibrio cholerae* is one of the most infamous pathogens of all time. *V. cholerae* has acquired myriad adaptations—particularly related to biofilm behavior and virulence—to allow its survival and aggressive proliferation in the presence of antibiotics, environmental stressors, and host immune defense. A biofilm is a conglomeration of bacterial cells attached to a surface and encased in an extracellular matrix containing polysaccharides, genetic material, enzymes, and metabolites. Founder cells are typically immotile and directly attached to the surface, and “younger” cells are more motile and closer to the periphery of the biofilm. Biofilms are critical for bacterial survival: They confer protection from antimicrobials and environmental stressors, opportunities for horizontal gene transfer, and essentially an “external digestive system” in which cells can exchange metabolites. Biofilm association has also been shown to induce a hyperinfectious phenotype in *V. cholerae*. The Bimczok Lab has observed peculiar biofilm behavior in *V. cholerae*: in response to nitric oxide (an antimicrobial released by the human small intestine), and a host epithelial surface (modeled by Caco-2 line colorectal adenocarcinoma cells and mechanical agitation), the bacteria form unattached aggregates with immotile bacteria on the surface and motile bacteria within. We have termed these unprecedented inside-out biofilms “vibrioids”. We have discovered that vibrioid formation occurs in both wild-type and nitric oxide-sensor knockout strains, suggesting that factors beyond nitric oxide affect vibrioid formation. I am currently exploring the mechanisms of vibrioid formation and dispersal. Experimenting with fluorescent and non-fluorescent strains, I will observe whether vibrioids form via binary fission from a single parent cell, aggregation of existing cells, or a combination of the two. As a model organism, a better understanding of this phenomenon in *V. cholerae* will enhance our knowledge of bacterial proliferation and infectivity in general.

Abstract Name: Body as Method: Choreographic Process and the Translation of Experience in the Works of Bill. T Jones, Rennie Harris, and Martha Graham

This research examines the question: How do different choreographic processes shape the translation of emotional experience to an audience? Is there a process that works best? By analyzing Rennie Harris’s *Exodus*, Bill T. Jones’s *Still/Here*, and Martha Graham’s *Lamentation*, the research explores how

choreographers construct emotional worlds through embodied experience and the development of movement vocabulary. I selected these works because each one uses the body as a primary method for communicating human experiences such as; grief, illness and cultural trauma, offering a valuable lens for understanding how process impacts audience interpretation. This project aims to open broader conversations within dance studies about the relationship between choreographic method and audience understanding. It also directly informs the development of my own choreography, in preparation for my Senior BFA work, which will draw from personal experiences with illness and healing. Studying these works allows me to investigate how choreographers translate memory, pain, and resilience into physical forms. Methodologically, this project uses analytical comparison of choreographic structure, rehearsal strategies, and movement choices surrounding each work. Harris builds movements rooted in Hip-Hop community practices and sociopolitical realities; Jones conducts survivor workshops, integrating gesture mirroring and multimedia testimony; Graham uses symbolic costuming and contraction-based movement to capture universal grief. These varied processes illuminate how choreographers use the body as research and communication. The study concludes that while each artist effectively conveys emotional depth and choreographic methods, pathways leading to universal audience comprehension may always be blurred. Experience is not universal. Viewers interpret movement through their own lived experiences and cultural backgrounds bringing a unique lens that shapes how they understand and connect with a work. These findings have significantly influenced my own creative process, prompting me to consider how embodied research and personal narrative can shape my choreography, while still leaving space for individual interpretation.

Abstract Name: Urinary Tract Infections Alter Nrf2 Pathway in Brains of G2019S-LRRK2 Transgenic Mice

Parkinson's disease (PD) is one of the fastest-growing neurodegenerative disease, affecting over 11 million people globally. This rise persists even after adjusting for an aging population, suggesting that environmental factors may be significant contributors. Increased PD risk has been linked to exposure to environmental toxins, gut dysbiosis, and infections. Although PD pathogenesis is not fully understood, increasing evidence suggests that neuroinflammation has implications in PD onset and progression. Mutations in the Leucine-Rich Repeat Kinase 2 (LRRK2) protein contributes to both genetic and sporadic PD. LRRK2 is expressed in neurons and various immune cells (e.g., microglia, B cells), highlighting its role in neuroimmune reactions. In our studies, we found that urinary tract infections (UTIs) induced microglial activation in the brains of G2019S-LRRK2 transgenic mice. UTIs also appeared to elevate Nrf2 levels and promote its nuclear translocation, and an Nrf2 activator, Omaveloxone, significantly further increased Nrf2 levels and its nuclear translocation in brains of G2019S-LRRK2 mice. Omaveloxone also decreased the UTI/G2019S-LRRK2-induced 4-HNE levels, suggestion Omaveloxone's therapeutic potential in reducing and limiting oxidative stress. Together, these preliminary findings suggest that peripheral infections like UTIs can trigger neuroinflammatory responses and alter the Nrf2 pathway. In the future, we will further dissect the link between infections and PD pathology and explore Nrf2-targeted strategies as potential therapeutic interventions.

Abstract Name: Cyborg Roots: Rethinking George Washington Carver in the Context of Black Children's Literature

African American children's literature puts into words and pictures the stories that have been orally told for generations as new stories from the imagination. Nonfiction children's literature utilizes George Washington Carver's story to help students view science as a human endeavor. The relationships between facts and what many refer to as "the nature of science" attribute to the characterization of Carver and his importance to science. Through images, acknowledgements, and citations, the depictions establish authority over the facts of Carver's story. Little attention has been given to how authors imagine Black futures through their historical depictions of George Washington Carver. The author's choices to challenge authority invites readers to critically engage with the informational text through questioning. In this paper, we argue that George Washington Carver's initial emergence in children's literature symbolized the invention of a "Black Cyborg" in nonfiction children's literature. To investigate, a codebook was generated based on Sanders and Bishop, with sub-codes from Ford. The books were selected as narrative nonfiction and published before 1959 in accordance with Bishop's restrictions applied to develop the three categories for fiction. The books selected were George Washington Carver Scientist by Shirley Graham (1944); The Story of George Washington Carver by Arna Bontemps (1944); Carver's George by Florence Means (1952); and Boy scientist by Augusta Stevenson (1954). The diverse publication dates and authors encapsulate the change in the conceptualization of Carver's story. Our paper concludes that the construction of Carver's story should not be taken as fact, but rather it should be seen as a literature of questions. His story has always been used to advocate for the educational liberation of Black people, inspiring Black futures in science. The ways in which authors challenge authority affirm that his story is never objective.

Abstract Name: The Heart Behind the House

This creative work explores a semester collaboration at Jacksonville University with the Ronald McDonald House Charities. Working together, English, History, and Communication students took an interdisciplinary approach to a video documentary project: The Heart Behind the House: Ronald McDonald House Charities. This documentary style video project integrates effective communication strategies, utilizing video production, script writing, extensive interviews, and strategic social media initiatives to effectively communicate the mission and service of the Jacksonville location. Qualitative interviews with patients and families, community volunteers, and RHMC executives serve as the foundation for the video stories, skillfully crafted by undergraduate student journalists. The collection of video narratives features in-depth interviews, on-location b-roll and includes strategic social media content designed for public outreach. With on-camera interviews and the expertise of advanced communication students, this project highlights the

greater Northeast Florida community and the compassionate service and work of the RMHC in Jacksonville, Florida. The goal of this video is to elevate public understanding surrounding the local work of RMHC and inspire viewers to support the mission of the organization specializing in service to children and families in need of health care.

Abstract Name: Purification and Functional Analysis of Membrane Serine Proteases: The Prostasin-Matriptase Cascade

Matriptase and prostasin are membrane-anchored serine proteases that have opposing functions: matriptase is an oncoprotein and prostasin is a tumor suppressor. Both proteins are normally expressed only in epithelial cells, where they regulate each other to maintain epithelial homeostasis. Certain subtypes of B-cell lymphomas over-express matriptase in the absence of prostasin, which is thought to promote cancer progression. Genetically engineered prostasin expression in the matriptase-expressing B cells induced the proteolytic cleavage and shedding of matriptase from these cells, resulting in slower growth and increased cell death. In this study, we hypothesized that prostasin and matriptase directly interact and activate each other in a cascade facilitating matriptase cleavage/shedding. To test this hypothesis, stable cell lines expressing matriptase or prostasin were used to prepare cell lysates for protein isolation. Purified matriptase and prostasin were mixed, incubated for various time periods, and then analyzed by means of western blots. We observed a reduction in the total protein quantity of both matriptase and prostasin and the appearance of a small fragment of matriptase, presumably the cleaved product. The results suggested that prostasin and matriptase could activate each other, leading to the downregulation of matriptase and its oncogenic effects. Our work could be a foundation for future studies on the prostasin-matriptase proteolytic cascade and a possible therapeutic strategy for B-cell lymphoma.

Abstract Name: Frequency of Vascular Aging in Young Adults

Arterial stiffness is an early indicator of cardiovascular aging, yet its presence in young adults remains understudied despite rising reports of early cardiometabolic risk. Current research raising concerns about premature vascular issues in younger individuals inspired this study. This project investigates the vascular age of individuals 18–26 years old by examining acute changes in arterial stiffness post submaximal exercise. Our goal is to determine whether small changes in arterial health can be identified before more common cardiovascular risk factors appear. Using high-resolution vascular ultrasonography and applanation tonometry, diameters and pressures of the carotid and radial arteries will be measured to assess arterial elasticity. A cross-sectional protocol will be used in which participants complete baseline assessments of

anthropometry, blood pressure, body composition, and vascular function before performing a graded cycling test to 85% of age-predicted maximum heart rate. Arterial stiffness will then be measured 5 minutes post-exercise and again 90 minutes later to evaluate immediate and short-term vascular responses. Expected results include a detectable increase in arterial stiffness immediately following exercise. In healthy individuals, levels are expected to return to baseline after the 90-minute recovery period, depending on fitness level. Some participants may show atypical patterns, which could serve as an early indication of increased vascular risk. The statistical approach implemented in this study will be used to examine changes in arterial stiffness across time points and to assess whether the order of measurements influences the results. This experimental approach based on exercise physiology integrates practical tools from clinical vascular assessments. Results will help us understand whether acute exercise can expose early signs of vascular dysfunction in young adults. Overall, the goal is to improve early identification of cardiovascular risk and support heart health in young adult populations, while also guiding future research on factors that influence vascular aging.

Abstract Name: Mucoïd: A Potential Roadblock to Phage Therapy

Bacteriophages ('phages') are viruses that infect bacteria and are a potential alternative to antibiotics. Phage U136B is obligately lytic and infects *Escherichia coli* using antibiotic efflux pump, TolC. However, just as bacteria evolve resistance to antibiotics, they can do the same with phage. Understanding factors that drive resistance evolution is crucial to determine efficacy of potential phage therapy use. In previous work, *E. coli* K12 evolved resistance to phage U136B via tolC or LPS biosynthesis gene mutations. However, a lower proportion of phage-resistant isolates had a mucoïd phenotype. In additional testing, mucoïd isolates were found to be more resistant to clindamycin than wild type. We hypothesized that selecting with both phage U136B and clindamycin would increase the frequency of mucoïd mutants. To test this, we conducted a plate-based selection experiment with phage-clindamycin combination and quantified the frequency of mucoïd mutants. Mucoïd mutants appeared at high frequencies under these conditions. Whole genome sequencing revealed that mucoïd isolates had mutations in Rcs Phosphorelay genes, the pathway regulating synthesis of colanic acid and the mucoïd phenotype. In addition, we found a low frequency of clindamycin and phage-resistant non-mucoïd mutants. These mutants all had missense mutations in tolC, resulting in predicted changes to the extracellular region of TolC. We then performed a 5-day evolution experiment, selecting wild type bacteria with clindamycin and phage U136B. Once again, we saw mucoïd evolve after one day of selection with phage U136B and clindamycin. However, after five days, the mucoïd phenotype disappeared and was outcompeted by tolC missense mutations. Our work suggests that while mucoïd is a common adaptation under certain combinations of phage-antibiotic selection pressures, the phenotype is transient compared to longer-term receptor modifications. Overall, resistance evolution reveals the need to consider the entire genetic potential of hosts in treatments like phage therapy.

Abstract Name: Navigating Undergraduate Research in the Digital Era: A Qualitative Analysis of Faculty Digital Practices and the Visibility of Undergraduate Research Opportunities

Participation in undergraduate research fosters intellectual curiosity and gives participants confidence in their respective disciplines. Despite the benefits of undergraduate research, there is little research as to how faculty communicate to prospective students about the availability of undergraduate research opportunities. Effective communication of undergraduate research opportunities, especially through digital channels, is essential to the overall accessibility of undergraduate research to students. To address this gap, this study aims to catalogue the way faculty at a public, R2 university communicate information about undergraduate research online. The webpages and department biographies of the undergraduate, full-time, tenure-track faculty at a large southeastern university will be examined; in its completion, data from over 1000 undergraduate faculty members will be included. Preliminary data from education, humanities, chemistry, and social sciences show that faculty frequently do not mention undergraduate research in their department's biography, faculty webpage, or linked external websites. We expect to find that STEM disciplines will be more likely to include mention of undergraduate researchers compared to other disciplines due to the strong emphasis on undergraduate research embedded within those disciplines. We also expect that assistant professors will be more likely than associate and full professors to include mention of undergraduate research on their sites as they are establishing their presence as professors. The results of this study will help improve the undergraduate researchers' experience due to the ability to better connect with faculty that align with their research interests and navigate the undergraduate research process.

Abstract Name: How Tobacco Companies Exploit Social Media to Target Teenagers

The tobacco industry invests heavily in marketing and is increasingly targeting young people on social media. Research shows that a substantial majority of teenagers report exposure to e-cigarette advertising through digital platforms. This follows a pattern Sam Kean describes in *The Icepick Surgeon*, in which medical professionals throughout history have obscured harm through the selective presentation of data. Tobacco companies use social media to manipulate young consumers through influencer marketing, algorithm-targeted content, and carefully curated brand narratives that minimize health risks. While researchers have studied traditional tobacco advertising, the billboards and TV commercials of the past, a systematic analysis of how companies exploit digital platform algorithms to normalize nicotine use among youth, particularly through influencer networks and co-opted social justice messaging, has not been comprehensively addressed. We discovered that companies use sophisticated strategies, including micro-influencer partnerships, that do not always clearly disclose paid promotional relationships. They design content to bypass platform advertising restrictions through algorithmic optimization. They associate vaping with social justice movements to make products seem progressive. These tactics work like the misdirection Kean describes, where harmful products are made to appear safe and socially conscious. By embedding advertisements within content that appears organic and authentic, companies achieve what Kean warns about: making harmful practices look beneficial. With limited public awareness of manipulation tactics, platforms struggle to regulate these evolving practices effectively, and rapidly evolving digital marketing techniques enable continued exploitation despite growing concerns. Our findings demonstrate how historical patterns of scientific deception translate into digital spaces. This research can help shape platform regulation policies and youth media literacy curricula.

Abstract Name: Characterizing neutrophil reactive oxygen species production during interaction with *S. aureus*

Staphylococcus aureus (*S. aureus*) is a typical commensal bacterium of human anterior nares that is estimated to permanently colonize ~30% of the population. *S. aureus* is also a predominant infectious pathogen that bears a considerable burden on the healthcare industry, carrying significant morbidity and mortality. Once largely restricted to hospital environments, multi-drug resistant strains of *S. aureus* are now commonplace in community settings. These strains have the ability to avoid normal immune cell killing and cause disease in healthy individuals. Despite decades of research committed to understanding *S. aureus* virulence, much is still unknown and mechanisms for how *S. aureus* can escape the defenses of the body are incompletely defined. The *SaeR/S* regulatory genes have been implicated in *S. aureus*' survival of the immune system's oxidative killing response utilized by neutrophils. Upstream genes within the operon of *saeR/S* – *saeP* and *saeQ* – are believed to play an additional role in *S. aureus*' survival of the immune system. We measured chemiluminescence-based production of two reactive oxygen species (ROS), O₂⁻ and H₂O₂, as a qualitative marker to explore the importance of *SaeP* and *SaeQ* in the bacteria's resistance to neutrophil-mediated degradation. A wild type of *S. aureus* has been shown to meter the neutrophil's initial burst release of ROS in contrast to the *saeR/S* deletion mutant. The resulting data suggests that *saeQ* plays a similarly important role in *S. aureus*' survival as *saeR/S*. This work will be expanded to include various immunomodulators (i.e., rapamycin, 3-MA) to understand how the functions critical to neutrophil killing are linked, and how *S. aureus* can survive them.

Abstract Name: Development of Tunable Rose Bengal-Based nanoGUMBOS as Potential Selective Chemotherapeutic Agents

As cancer remains one of the greatest threats to the global population, the development of chemotherapeutic agents that are selective and tunable is of critical importance. Herein, a series of Rose Bengal (RB)-based GUMBOS, a group of uniform materials based on organic salts, were synthesized via counterion exchange between [Na]₂[RB] and three organic cations: tetrabutylphosphonium bromide [TBP][Br], tetraphenylphosphonium chloride [TPP][Cl], and 1-dodecyl-3-methylimidazolium chloride [C₁₂MIm][Cl]. The resulting GUMBOS were characterized through FT-IR, ESI-MS, NMR, and UV-Vis Spectroscopy. Partition coefficient studies indicated all GUMBOS exhibited hydrophobic physiochemical characteristics. These hydrophobic RB-based GUMBOS were formed into nanoparticles via reprecipitation method and exhibited average diameter sizes below 85 nm with moderately negative zeta potentials all below -30 mV.

Permeability through biological membranes was assessed by an in vitro PAMPA assay, revealing enhanced passive diffusion at 10 μ M solutions. The cytotoxic activity of the nanoparticles was assessed in A549 lung carcinoma cells as well as the noncancerous HEK239 human embryonic kidney cells. The A549 cell line exhibited mainly apoptotic characteristics, with a lower average cell viability of 22.6% from treatment with [C12MIm]₂[RB] nanoGUMBOS. Moreover, the HEK239 cells exhibited a higher viability of 47.1% with the same treatment. IC₅₀ of the [C12MIm]₂[RB] nanoGUMBOS treatment on cancerous cells was 2.16 μ M, with a selectivity index of 2.1. These findings demonstrate the novelty of RB-based nanoGUMBOS as tunable and selective chemotherapeutic agents.

Abstract Name: *Æmilia Lanyer's Dedicatory Verses: The Construction of Meaning in Salve Deus Rex Judæorum*

Probably the first woman writing in English to produce a substantial volume of poetry designed to be printed and to attract patronage, the Renaissance poet *Æmilia Lanyer* created an essential contribution to the rich collection of early modern women's writing with her *Salve Deus Rex Judæorum*. Reintroduced to modern literary consciousness by historian and William Shakespeare biographer A. L. Rowse in his 1973 edition of her poetry, *The Poems of Shakespeare's Dark Lady*, Lanyer has not always received the critical attention she deserves. In his edition of Lanyer's poetry, Rowse argued that Lanyer was the "dark lady" of Shakespeare's final twenty-eight sonnets—a claim that drew far more attention to her biography than to her poetic achievement. Despite this, the work of scholars Barbara K. Lewalski and Elaine V. Beilin in the 1980s began the significant reappraisal of Lanyer's work, emphasizing the ways her poetry challenges Jacobean patriarchal discourses. Lanyer's volume includes nine dedicatory poems to noblewomen such as Queen Anne as part of her bid for patronage. While scholarship on these dedicatory verses exists, literary critics have largely read them through the lens of the early modern patronage system. Because dedicatory poems are often dismissed as mere flattery designed to solicit financial support, their literary and thematic significance has been undervalued. As a result, this presentation argues that Lanyer's dedicatory poems are integral to the structure and purpose of *Salve Deus Rex Judæorum*. This presentation is an analysis of these patronage poems as a deliberate literary strategy through which Lanyer constructs a community of virtuous women and establishes themes she later develops in the title poem "*Salve Deus Rex Judæorum*" and in "*The Description of Cooke-ham*."

Abstract Name: Ballistic Testing on Additively Manufactured Flexible Bio-Inspired Armors

Current body armor, typically composed of Kevlar or composite ceramics, is often heavy, restricting the user's range of motion. Furthermore, rigid armors can cause projectile fragmentation upon impact, creating a risk of ricochet injury. Nature provides examples of highly efficient evolved defenses, such as the scales of gar fish or pangolins, which offer high mobility without sacrificing protection. This study aims to create and evaluate

the ballistic effectiveness of flexible, bio-inspired armor configurations using additive manufacturing. The research compares a control group of solid 3D-printed square profiles against four bio-inspired configurations: a fish scale pattern, layered hexagonal plates based on the honeycomb cowfish, layered circular plates based on trout and salmon, and a staggered spiked design inspired by pangolins. Samples are subjected to high-velocity ballistic firing and low-velocity impact testing using an Instron CEAST 9450 with custom indenter tips. High-speed cameras recording at high frame rates to capture the impact events, utilizing Digital Image Correlation (DIC) to analyze projectile velocity and kinetic energy changes. By calculating energy absorption, this project identifies which configurations provide superior strength relative to weight. The results intend to demonstrate that bio-inspired designs can reduce material requirements and enhance mobility while preventing projectile fragmentation, contributing valuable insights to materials science for military and civilian applications.

Abstract Name: 2,5-ditert-butylhydroquinone (dtBHQ) exposure affects motor behavior and axonal organization in zebrafish

In partnership with the ALS Association, a study on the spatial distribution of ALS in Virginia was conducted. Our group identified geographic clustering or “hotspots” with increased risk of contracting ALS. An analysis of drinking water from the households of ALS patients revealed the presence of a novel toxicant dtBHQ (2,5-ditert-butyl-hydroquinone) at higher rates than control samples. dtBHQ is a specialized stabilizer and antioxidant used during the production of plastics, and has been shown to induce muscle weakness and disrupt motor endplates in rats, suggesting a potential role as an environmental toxin that contributes to sALS. However, few studies have examined the developmental neurotoxicity and the degenerative effects on mature axons by dtBHQ. In this study, zebrafish (*Danio rerio*) were waterborne exposed to dtBHQ (up to 3nM) starting at 24 hours post-fertilization (hpf). Motor behavior was assessed through touch evoked response (TER) and free-swimming assays at various developmental stages. Our data indicate that dtBHQ exposure significantly affected locomotor function, with decreased TER and free swimming distance and frequency. Consistent with these motor deficits, dtBHQ disrupted axon growth and branching of primary and secondary motor neurons during early developmental stages. The neurotoxic effect of dtBHQ on motor phenotype does not depend on neurodevelopmental timepoint of exposure, since exposure on day 3 leads to similar locomotion deficits and axonopathy. Taken together, our findings indicate that dtBHQ exposure-driven locomotion deficits are likely driven by the abnormalities in axonal growth and organization. Our goal is to characterize neuromuscular junction integrity following toxicant exposure and identify the molecular mechanism underlying dtbhq-mediated motor behavior deficits.

Abstract Name: Quantitative Analysis of ZnT3 Expression in Postmortem Schizophrenia Dorsolateral Prefrontal Cortex Layer 3 Pyramidal Neurons

Background: Cognitive deficits are a core feature of schizophrenia (SZ) and are thought to arise from impaired neuronal signaling within the dorsolateral prefrontal cortex (DLPFC). We hypothesize that altered zinc transporter ZnT3 expression may contribute to reduced pyramidal neuron (PN) activity and cognitive deficits. This project aims to evaluate ZnT3 expression within layer 3 (L3PNs) of the DLPFC in SZ. Materials and Methods: Fresh-frozen human postmortem DLPFC tissue samples from four subject pairs of SZ and unaffected comparison (UC) subjects were labeled for genes SLC17A7 (VGLUT1) and SLC30A3 (ZnT3) via in situ hybridization and co-labeled with DAPI nuclear stain. DLPFC 3D images were analyzed using QuPath software. DLPFC L3 was delineated using DAPI, and L3PNs were identified using intensity-based VGLUT1 segmentation. Subcellular mRNA grain detection quantified L3PN VGLUT1, ZnT3, and nuclear size. VGLUT1+ cells were randomly sampled to yield 250 cells/subject. Results: Results have not been statistically assessed due to small N. ZnT3 and VGLUT1 mRNA grain counts were 14% higher and 7% lower in SZ (7.5 ± 5.0 ; 17.3 ± 7.9) than UCs (6.6 ± 4.9 ; 18.5 ± 8.3), respectively. Nucleus area was 7.2% larger in SZ (96.5 ± 35.5) than in UCs (90.0 ± 28.6). When accounting for nuclear area, the same pattern was revealed, where ZnT3 and VGLUT1 mRNA grain density/cell was 8% higher and 14% lower in SZ (0.08 ± 0.05 ; 0.18 ± 0.06) than UCs (0.07 ± 0.05 ; 0.21 ± 0.07), respectively. However, the data across both diagnostic groups were highly variable. Conclusion: These findings indicate small changes of ZnT3, VGLUT1, and nuclear area in SZ L3PNs, with the potential presence of distinct subgroups of L3PNs with differing ZnT3 expression.

Abstract Name: The Effects of Systematic Determinance on Oral Health Disparities: A Comprehensive Review of Cultural, Social, and Linguistic Barriers

Oral health disparities prevail as one of the most prominent health issues seen in our society today. However, it is often overlooked and viewed as a cosmetic aspect of healthcare rather than a vital component of an individual's health status. Due to the continuous dismissal and disregard of dental care as a critical component of healthcare, many underserved communities remain hindered. This comprehensive literature review explores how systemic exclusion, cultural incompetence, socioeconomic determinants, and linguistic barriers contribute to the unequal distribution of oral care seen in the United States. It becomes imperative to inquire how these specific health disparities affect oral health experiences for underserved communities, and further, what the broader implications of that relationship are for long-term care. This paper raises awareness for those underserved and provides valuable insights on dental disparities, approached through a cultural and social lens, further emphasizing the importance of broader implications for long-term care and the need for advocacy for marginalized communities. Prevalent counterarguments claim that dental education systems provide dental students with the necessary resources vital to their success in the dental workforce, ultimately arguing that dental schools successfully prepare students to provide equally accessible care to all patients, regardless of background. The evidence for this is acknowledged, yet it is deemed unstable due to the evident gaps presented in the literature. By engaging in scholarly research that discusses immigrant experiences, structural racism, and inequalities regarding access to preventative care, this paper underscores the need for proper structural and educational reforms in dental education systems, aiming to produce culturally competent dental professionals. Keywords: dental disparities, oral care, minorities, inequality, cultural competence, systematic exclusion

Abstract Name: Characterizing the Effects of Rotor Separation and Blade Design on Thrust Measurements for a Small-Scale Conventional Drone

Evaluating drone blade performance is crucial for optimizing drone efficiency. Blade separation, and camber percent are some of the most important parameters that determine blade performance. This is determined by measuring thrust at various operating conditions for differing blade design parameters. One common problem in these tests relates to the thrust stand itself, as they are usually expensive, complex, and not practical. A thrust stand was designed to investigate the impact of blade design parameters on thrust generated at various operating conditions. This design involves a prototypical drone placed on an S-type 20kg load cell that's connected to a HX711 load amplifier. A power supply is used to control the drone rotors' rotational speed. A tachometer was used to measure rotational speed. Before the experiments, a calibration curve with predetermined weights was used to gauge the load cell's response. In a previous study of measuring thrust from a small dual-rotor helicopter, NACA Airfoils 0018, 2418, and 4418 were tested. It was found that increasing camber results in increased thrust, as NACA 4418 (4% Camber) had the largest overall thrust production. For this experiment, the same set of NACA airfoils were employed. Initial data indicates a strong relationship between camber percentage and thrust generated, supporting our hypothesis that camber percentage and separation are the most important factors when optimizing drone performance. The airfoils are mounted on four rotors of the custom-built drone, and are currently under investigation. Preliminary results still validate our previous study. Drone arms were built with the option of vertical adjustment between the pairs of rotors. Additional study incorporates the thrust measurements as a function of blade rotor vertical separation at fixed operating conditions (i.e. at fixed rpm). Comprehensive findings and the impact of other blade parameters will be presented at the forthcoming conference.

Abstract Name: Characterizing Recycled PET Fiber Extracted From Plastic Bottles With and Without PLA Inclusion

Single-use polyethylene terephthalate (PET) water bottle production and disposal on a global scale contributes to waste management systems and environmental sustainability. An SJSU created bottle to filament recycling system aims to assess real-world applications of PET recovery. This system creates a 3D-

printing filament from 2-liter discarded PET bottles. This is achieved through a slicing method (8-9 mm strips) and extrusion (235°C), one filament produced from one two-liter bottle. Mechanical testing occurs for various sizes of strips, various temperatures of extrusion, and various winding speeds. A tensile test was performed on the resulting filament using an Instron 1 kN frame for ultimate tensile strengths (0.4-0.8 N) to establish baseline mechanical properties of recycled filament. In parallel, shredded PET bottles are blended with commercial PLA fiber in a hybrid method to create blended PET-PLA filaments. This system utilizes a commercial Single Screw Filament Extruder by HQHAOTWU for its constant heating and screw-feed parameters to assess the possibility of hybridized outcomes for further recycling efforts. Pure filaments from each system at SJSU and commercial systems will be compared for consistency and mechanical properties by processes of formation. A tensile test will also be performed on the hybrid PET-PLA fibers to assess stress, strain, extensibility and ultimate tensile strength compared to pure PET to assess if the blended ratios impact printability and mechanical reliability of recycled PET filament. Thus, this project accounts for multiple avenues of successful recycling of plastic materials and determines systems/processing factors that may improve the application of recycled plastic fibers. The created low-tech, in-house application at SJSU with commercial availability shows that waste PET can become valuable materials for additive manufacturing without sacrificing other plastic waste goals of circular economy endeavors. Project details and PET and blended PET-PLA fibres characteristics will be presented in the conference.

Abstract Name: Comparative analysis of Dementia Patients and Non-Dementia Patients Using Text Mining

This study presents a comparative quantitative analysis of spoken language between dementia patients and non-dementia individuals, utilizing text mining techniques to uncover diagnostic patterns. With the rapid aging of the global population, the early detection of and subsequent intervention for dementia have emerged as increasingly critical public health challenges. Conventional screening protocols, such as the Mini-Mental State Examination (MMSE), are resource-intensive, requiring administration by specialists, and often induce significant psychological stress in subjects. Consequently, there is an urgent demand for non-invasive, accessible detection methods that can be seamlessly applied within the context of daily life. This research aims to identify specific linguistic markers for early detection by quantitatively comparing speech data from patients with mild dementia against that of healthy controls. For the dataset, we analyzed 200 episodes from the "Narratives of Dementia" database representing patients, alongside control data derived from the "Corpus of Everyday Japanese Conversation." Following transcription, we performed morphological analysis to extract nouns, verbs, adjectives, and adverbs, followed by frequency and co-occurrence network analyses to examine vocabulary usage and structural patterns. Our analysis revealed clear quantitative and qualitative disparities. Dementia patients exhibited a significantly lower frequency of concrete nouns compared to controls, reflecting word-retrieval difficulties (anomia). Conversely, there was a marked prevalence of demonstrative pronouns (e.g., "that," "it") and verbs related to cognitive states (e.g., "forget," "do not know"). Furthermore, co-occurrence network analysis indicated that the speech networks of dementia patients were characterized by weak lexical associations and small, isolated clusters focused on specific anxieties or limited topics. These results suggest that the usage patterns of demonstratives and cognitive verbs, combined with fragmented network structures, indicate the potential for early identification. Ultimately, this study demonstrates that analyzing linguistic features in daily conversation serves as an effective, non-invasive biomarker for the early screening of cognitive decline.

Abstract Name: Outcomes of Orthopedic Surgeries in Patients on GLP-1 Agonists

Glucagon-like peptide-1 (GLP-1) receptor agonists are medications primarily used for Type II Diabetes Mellitus (T2DM) and more recently for obesity. GLP-1 agonist, such as semaglutide (Ozempic) and trizapatide (Mounajaro), have shown tremendous success for weight loss and glycemic control. GLP-1 is natural hormone produced in the body that is released after eating to maintains blood sugar and appetite. GLP-1 agonist are medications used to mimic these responses in the body. GLP-1 agonist has become increasingly widespread, likely due to rapid weight loss. However, new findings have shown that the use of these GLP-1 agonists have led to elevated risks of potential perioperative complications including bone weakness, reduced muscle function, etc. Comparatively, recent findings indicate the use of GLP-1 agonists preoperatively can lead to postoperative benefits such as decrease in mortality, increase in bone healing, potential in reducing infection and arthroplasty-related complications. To evaluate if GLP-1 agonist contributes a direct cause to these outcomes, researchers have gathered perioperative and postoperative data using statistical methods. Control groups in this situation are patients under standard care without any use of GLP-1 agonist. The independent group are patients who are taking GLP-1 agonist preoperatively for diabetic care, weight management, etc. Outcomes to be discussed are surgical complications, infections, injuries and any other procedure- specific complications. By comparing GLP-1 agonist users with non-users through logistic regression and more, these findings can allow us to gain a clearer understanding of association between GLP-1 agonist therapy and postoperative outcomes. With the findings from 6 medical journals via google scholars, we can access an overall conclusion to determine the outcomes in orthopedic cases due to the use of GLP- 1 agonist.

Abstract Name: Laser-Induced Breakdown Spectroscopy (LIBS) for Counterfeit Integrated Circuit Detection: Surface and Depth Analysis

Counterfeit integrated circuits (ICs) pose a growing threat to reliability, safety, and security across industries including medical, aerospace, and defense systems. Counterfeiting practices such as blacktopping—where used chips are recoated and re-marked to appear new—compromise performance and can lead to catastrophic failures. This research investigates Laser-Induced Breakdown Spectroscopy (LIBS) as a minimally destructive method for detecting blacktopped counterfeit ICs through combined surface and depth-layer analysis. LIBS directs a focused laser pulse onto the chip surface, generating a plasma plume whose emitted light reveals elemental composition. By performing repeated measurements across surface and subsurface layers, the method identifies compositional variations that distinguish authentic packaging from counterfeit coatings. Detection methods commonly combine physical inspection, electrical testing, and comparison to reference samples (“golden samples”) to evaluate authenticity. This study explores LIBS as a complementary approach capable of providing direct compositional data from both surface and depth layers while involving only limited material removal. Authentic and blacktopped samples are analyzed across multiple surface zones—text, scratches, indentations, and plain regions—to capture emission spectra at varying depths. Preliminary

surface analysis has identified elemental trends indicating higher carbon and oxygen levels in counterfeit coatings and stronger silicon signals in authentic packaging. The project now advances to depth profiling to evaluate compositional transitions and coating thickness. This work seeks to demonstrate that LIBS can accurately identify blacktopped counterfeit ICs and operate without reliance on golden reference samples. The findings will contribute to validating LIBS as a practical analytical method for counterfeit detection and expanding understanding of material composition differences between authentic and falsified components.

Abstract Name: The Role of DNA, Fingerprints, and Digital Forensics in Proving Guilt or Innocence

In today's criminal justice system, the difference between freedom and wrongful conviction often depends on the proper use of forensic evidence. This study examined the role of DNA, fingerprint, and digital evidence in determining guilt or innocence in criminal investigations. The purpose was to evaluate the effectiveness, reliability, and limitations of these forensic methods and to understand how they collectively support fair trials and strengthen modern criminal justice. Secondary research was conducted using peer-reviewed articles, textbooks, and credible forensic science sources. Methods included reviewing studies on the collection, analysis, and interpretation of DNA, fingerprint, and digital evidence. Results indicated that DNA analysis, when properly collected, accurately linked or excluded suspects, as demonstrated in a simulated DNA fingerprinting exercise where only 1 of 5 suspect samples matched the crime scene. DNA showed medium reliability (36%) due to potential contamination or misinterpretation. Fingerprint analysis, with a higher reported reliability (54%), effectively identified suspects through ridge patterns, even distinguishing identical twins when DNA could not. Digital evidence was found to be the least reliable (25%) because data can be altered, deleted, or mishandled, but it remains critical for reconstructing timelines, communications, and locations. Combining multiple evidence types consistently improved investigative accuracy and reduced the risk of wrongful convictions. The discussion highlighted the importance of proper evidence collection, handling, and analysis, as errors in any step can compromise outcomes. Findings emphasized the need for improved forensic training, standardized procedures, and advanced technology, including enhanced DNA testing, machine-learning-assisted fingerprint analysis, and robust digital forensic tools. Overall, this study reinforces that DNA, fingerprint, and digital evidence are essential and complementary tools in criminal investigations. Continued investment in forensic science, improved protocols, and technological advancement are crucial for ensuring justice is delivered fairly, efficiently, and reliably.

Abstract Name: Effects of Biofilm Releasing Agents on the Viability of HEK-293 Cells

Biofilms are associated with 80% of bacterial infections; this is due to their ability to group together and form a sticky extracellular polymeric substance (EPS), which increases antimicrobial tolerance. The purpose of this research is to determine whether different biofilm-releasing cues affect the metabolic and proliferation rates of HEK-293 cells, a key factor in evaluating their therapeutic viability. XTT and scratch assays assessed how each treatment affected cell metabolism and proliferation, offering insight into mammalian responses to dispersing agents. These releasing agents were selected for their distinct mechanisms of releasing bacterial cells from a biofilm: fatty acid signaling molecule (cis-2-decenoic acid) (cis-DA), nutrient (glutamate), environmental toxin (sodium nitroprusside) (SNP), and a glycoside hydrolase (alpha-amylase), which serves as an EPS-degrading enzyme. Despite their ability to disperse bacterial cells, their potential clinical applications remain unknown because of a gap in research on their toxicity to mammalian cells. The XTT assay measured metabolism of cells after varying treatment exposures: 30 min, 90 min, 3 hrs, 24 hrs, and 48 hrs. The XTT indicated no significant differences between the metabolic activity of HEK-293 cells treated with releasing agents compared to the control. There were, however, a significant decrease in metabolism when comparing absorbance of the 30-minute time point to later exposure times for each treatment. Alpha-amylase and glutamate induced decreased mammalian cell metabolism at 48 hours. Scratch assays were performed wherein treated mammalian cells were monitored for wound closure over 3 days. Scratch assay results were more conclusive, showing no significant differences in wound closure among treatments. These results combined support the ability of these biofilm-releasing agents to safely disrupt biofilms surrounding bacteria in potential clinical applications. This will be explored through future proliferation assays to measure cell growth at longer time points of exposure and aid in understanding scratch assay findings.

Abstract Name: The Impact of Methamphetamine Usage on Working Memory In Rat Model

The rise in recreational methamphetamine use has contributed to significant neurological risks among adults. Methamphetamine usage imposes mental and physical effects on brain function, including impairments in decision making and working memory linked to overall decreased function in the prefrontal cortex. The dominant explanation for this trend is that methamphetamine is a highly addictive psychostimulant that affects the way our brain creates chemical dopamine. Methamphetamine increases the amount of natural dopamine in the brain, which is what makes users experience the elevated high and euphoric feeling, leading to more usage of the substance. We used data from the Institute of Molecular Biosciences at Mahidol University to extract the reaction times of methamphetamine in a rat model. Testing reaction times involved examination of rats response times to sudden stimuli. Working memory allows you to hold and manipulate important information while coordinating other tasks. We focus on models of data that have been extracted from rats because of the ability to understand biological complexities of methamphetamine. Utilizing a rat model, the data will share key biological genetic similarities including parallel functioning of the prefrontal cortex, which houses executive processes such as working memory, providing a justified model to explore prefrontal cortex mechanisms in this study. Contrary to findings regarding impairment of decision making with the usage of methamphetamine, this study examines how methamphetamine use specifically impairs working memory, measured by reaction time performance and how these reduced reaction times demonstrate reduced efficacy of the prefrontal cortex. This study's findings suggest that methamphetamine does decrease function in working memory of executive processes in the prefrontal cortex.

Abstract Name: The Relationship Between Alcohol-induced Self-Inflation and One's Susceptibility to Illness Among College Students

Alcohol is woven throughout our culture, especially among college students. Despite more recent interventions and continuous research on the detrimental effects of drinking, alcohol-related consequences persist on college campuses. The Alcohol Myopia Theory may be one potential explanation for this. Alcohol myopia is the constraint of attention to solely the present moment due to the effects of acute alcohol use on attention processes. Alcohol Myopia Theory assesses different myopic outcomes: relief (anxiety reduction), excess (exaggerated behavior), and self-inflation (feelings of grandiosity). These effects may limit focus, leading to negative consequences. Perceived Susceptibility represents the belief of how vulnerable one is to infectious disease. Given alcohol's known myopic effects, there is a possibility that during drinking episodes, individuals may not attend to cues or perform behaviors that would limit exposure to illnesses. The focus of the current study is to examine the relationship between alcohol's myopic effects on self-inflation and perceived susceptibility to disease among college students. College students at the University of Cincinnati completed online surveys including both the Alcohol Myopia Scale and the Perceived Susceptibility to Illness Scale allowing us to examine their relationship. We hypothesized that greater self-inflation would predict lower perceived susceptibility. Self-inflation ($p=.750$)($r=-.015$), excess ($p=.079$)($r=.084$), and relief ($p=.083$)($r=-.083$) were all not significantly related to perceived vulnerability to disease. Self-inflation and relief showed a slight negative relationship, and excess showed a slight positive relationship. However, the total myopic effect ($p<.001$)($r=.178$) exhibited a slightly positive, significant relationship. This suggests that although the dimensions of alcohol myopia show no significant trends, there is an overall psychological trend that alcohol has on perceived vulnerability to illness. Taken together, these findings imply that the subscales of alcohol myopia operate collectively, rather than independently, to influence perceived vulnerability to illness.

Abstract Name: Evaluating the Impact of Dredging on PCB Pollutant Loads in the Hudson River Using Numerical Integration and Exponential Decay

To evaluate the impact of dredging as a remediation effort in the Hudson River, this study applies numerical integration techniques to estimate reductions in Polychlorinated Biphenyl (PCB) loads between the pre-dredging (2005–2008) and post-dredging (2018–2021) periods. PCB contamination in the Hudson River has been extensively documented through concentration monitoring, with studies noting its persistence in river sediments and long-term implications for human and aquatic ecosystem health. Existing research on the Hudson River highlights the Environmental Protection Agency's (EPA) PCB Dredging Project as a major remediation effort aimed at removing contaminated sediments that persist in the upper river. While previous studies provide monitoring data, this research examines the applicability of quantitative estimation techniques

for measuring changes in PCB loads. This investigation uses the Trapezoidal Rule on annual mean PCB concentrations and water flow rates from the pre-dredging and post-dredging periods to estimate the total PCB load reduction at the Waterford station, a key upper Hudson location for tracking downstream transport. Then, exponential decay is applied to predict the continued decline in PCB loads beyond 2021. Results reveal a 54.14% decrease in total PCB load, indicating that dredging significantly reduced contamination in the river. The exponential decay function predicts that an additional 443.54 kg of the pollutant will ultimately be removed from the Waterford station. These findings highlight the usefulness of quantitative estimation for analyzing long-term environmental recovery and informing future water quality management decisions. Further research could expand the dataset to capture additional monitoring data after 2021 and incorporate PCB measurements reported at more frequent intervals to account for seasonal variations in PCB transport.

Abstract Name: Tomato Leaf Anomaly Detection System

Early detection of crop diseases is essential for improving agricultural productivity, reducing labor demands, and preventing outbreak. This project presents a machine learning based anomaly detection system designed to identify tomato leaf diseases such as leaf blight, black spot, leaf mold, and bacterial spot. The system integrates real-time visual monitoring with trained deep learning models and is intended for deployment on a remote-controlled data-collection vehicle operating on the NCAT farm. Over the course of the semester, we developed and evaluated an end-to-end workflow encompassing data preparation, model training, testing, and performance analysis using a curated tomato leaf image dataset. We implemented three primary models YOLOv8, YOLOv11, and MobileNetV2 to compare classification and detection performance across different architectures. YOLO-based models leverage convolutional neural networks to localize diseased regions with bounding boxes, offering strong performance for real-time detection. MobileNetV2 served as a lightweight baseline for fast classification tasks. Through systematic training sessions, iterative tuning, and the integration of data augmentation techniques such as rotations, flips, and mosaic batching, the YOLOv11 model demonstrated the highest overall potential. Accuracy improved significantly throughout training, rising from 40% to approximately 72%, with final performance ranging between 70–75% on unseen validation samples. Our analysis highlighted key challenges including class imbalance, early accuracy plateaus, and the introduction of noise in real agricultural environments stemming from lighting variations, angles, and background clutter. Despite these constraints, YOLOv11 maintained reliable inference speed and strong detection capability suitable for embedded or mobile deployment. Future development will focus on expanding the dataset with images collected directly from the NCAT farm, deploying the trained model on edge devices with a user-friendly interface, integrating system compatibility with the RC vehicle, and extending the methodology to additional crop types. This work demonstrates the feasibility of a scalable and efficient vision-based tool for supporting modern precision agriculture.

Abstract Name: Curate This! Teaching the Art and Ethics of Museum Exhibition at Christopher Newport University

This presentation explores innovative approaches to teaching curating to future museum professionals at Christopher Newport University, with an emphasis on balancing theory, practice, and professional readiness. Curating is more than arranging objects in a gallery—it involves interpretation, storytelling, ethics, and a responsibility to diverse audiences. Preparing students for this complex role requires a pedagogy that is both practical and reflective, grounded in case studies and experiential learning opportunities. The session highlights strategies for developing students' curatorial judgment, including project-based assignments where they design and execute small-scale exhibitions, opportunities for collaboration with local museums, and exercises that emphasize critical thinking about representation, accessibility, and cultural sensitivity. By learning to evaluate objects and narratives through multiple perspectives, students build essential skills in research, interpretation, and communication. Attendees will leave the session with practical strategies for designing courses and assignments that prepare students for the realities of the profession. They will know how to integrate theory and practice, feel inspired to experiment with new teaching methods, and be ready to build partnerships with museums and communities that enrich student learning. Ultimately, this presentation demonstrates that teaching curating is not only about training students to arrange exhibitions, but also about empowering them to shape museums as inclusive, innovative spaces that connect meaningfully with society.

Abstract Name: The Role of Balance in Novel Videogame Monetization

Take Tic-Tac-Toe and contrast it to 1972's Pong. One game is perfectly fair, but the other provides a massive advantage to the first player and is arguably more math equation than game. However, mindful of exponential growth in videogame complexity, I propose several alternative goals to fairness in game balancing, or varying ways to interpret fairness in an inherently competitive system. How these emerging philosophies are impacting the artistic vision and financialization of videogames is examined. Engagement-based, skill-based, and randomized matchmaking are explained. The implications contained in pay-to-win, 'hat-to-win', and grind-to-win digital economies are contextualized. Gaming has many parallels with college admissions; namely, social class, social justice-inspired, and stats-driven admissions plans are quite comparable to the aforementioned approaches to digital game economies. I posit several (often competing) goals that universities seek to achieve through the admissions process. Must there be winners and losers, and is it zero-sum when so? Must we keep score? Can the admissions process be balanced from a metagaming dimension? Ultimately, this former professional esports-competitor-turned-law-student-hopeful provides a plan of action for the players—that is, the students—to play to win.

Abstract Name: I Can't Put It Down!: Parent-Child Relationships and Attachment Styles as Predictors of Smartphone Overuse in College Students

Recent studies show that 48%-60% of college students report behaviors consistent with smartphone overuse or addiction, with many spending a minimum of 4-6 hours per day (Umarji and Patel, 2024). Cell phone overuse in college students has detrimental effects including increased anxiety, poor sleep quality, procrastination and avoidant emotional coping patterns. Researchers have created a term for "technology based interference" (or "technoference") which refers to the disruption that smartphones cause to in-person interactions that can result in reduced relationship satisfaction and feelings of neglect (McDaniel & Coyne, 2016). The current study further examines how parent-child relationships and attachment styles predict smartphone overuse. The data collection for this study will occur in January 2026. All university students at a small, private, university in the northeast United States will be invited to complete an online survey using Alchemer with an incentive to win a gift card. Survey measures will include the: (a) Helicopter Parenting Index (Odenweller et al., 2014), (b) Attachment Style Questionnaire-Short Form (Iwanaga et al., 2020), (c) Mobile Maintenance Expectations Scale (Hall & Baym, 2011), (d) Digital Entrapment Scale (Hall & Baym, 2011), and (e) Actual Cell Phone Usage Form created by the authors that asks participants to report the actual average and total phone use time over the past week based on statistics from their phone settings. We hypothesize that students reporting intrusive or overbearing parental relationships will demonstrate higher levels of phone use, greater digital availability toward parents, and stronger feelings of entrapment. Insecure-anxious attachment is predicted to correlate with increased phone use, higher digital availability, and stronger feelings of entrapment compared to avoidant and secure attachments. Results of this study can educate students about how their relationships with their parents correlate with their phone use, especially for students who feel emotionally dependent on their phone.

Abstract Name: The Effect of Pulsatility Loss on miRNA Expression in the Vascular Endothelium of Continuous Flow-Left Ventricular Assist Device (LVAD) Patients

Background: Continuous-flow Left Ventricular Assist Devices (CF-LVADs) are standard therapy for patients with end-stage heart failure. patients with end-stage heart failure. However, the absence of pulsatile blood flow imposes non-physiological stresses on the vascular endothelium, disrupting normal homeostasis and contributing to vascular dysfunction. MicroRNAs (miRNAs) are known to play an important role in endothelial function and disease progression and understanding their role in specific situations can potentially offer insights into endothelial responses to non-physiological conditions in CF-LVAD patients. **Aims:** This study aims to identify mechanosensitive miRNAs differentially expressed in vascular endothelial cells under CF-LVAD conditions using publicly available RNA sequencing dataset and validate their expression through in vitro analysis. **Methods:** In this study, we first performed a bioinformatic analysis of publicly available datasets to identify miRNAs differentially expressed in CF-LVAD patient conditions compared with the normal physiological state, using GEO2R software. The significantly altered miRNAs were then further validated experimentally by mimicking CF-LVAD continuous stretch in vitro using our well-established vascular pulse perfusion model (VPPM). Human umbilical vein endothelial cells (HUVECs) were exposed to

either cyclic stretch (physiological) or constant stretch (CF-LVAD), and transcriptional levels of the candidate miRNAs were quantified using TaqMan qRT-PCR. Results: Computational analysis revealed that non-physiological flow in CF-LVAD patients distinctly modulates the transcriptional expression of several miRNAs, including hsa-miR-93, hsa-miR-423, and hsa-miR-22. In contrast, our VPPM experiment showed that miR-93 was significantly down-regulated under constant stretch compared to cyclic stretch condition. Additionally, miR-423 and miR-22 showed no statistically significant changes in expression irrespective of the type of stretch. Conclusions: These findings demonstrate that miR-93 is a mechanosensitive regulator of vascular endothelial dysfunction in CF-LVAD patients and suggest that miR-93 could potentially be used as a biomarker and therapeutic target for managing vascular complications in these patients.

Abstract Name: Identifying Social Computational Phenotypes in Psychopathology

Learning about others and making adaptive social decisions is essential for healthy functioning, and impairments in these processes are symptomatic of many mental disorders. Despite this, research linking psychopathology to social learning and decision-making (LDM) remains sparse. Existing work is limited in scope, focusing on specific disorders and/or assessing only nonsocial LDM. Recently, clinical psychological research has shifted from traditional diagnostic frameworks with symptom overlap and high comorbidity toward dimensional models. The Hierarchical Taxonomy of Psychopathology (HiTOP) is one such framework that organizes symptoms along data-derived transdiagnostic spectra, offering a more flexible and comprehensive view of psychopathology. Here, we use model-based approaches to examine how variation in different aspects of social LDM maps onto HiTOP spectra. Online participants ($N = 1,000$; recruited via Prolific) will learn about the trustworthiness of social and nonsocial targets while completing a version of the Trust Game where they decide how many points to send to each target (20 rounds/target, 2 social and 2 nonsocial targets per block, randomly intermixed). Across blocks, learning will be guided by three feedback types (information-only, reward-based, and social). Targets will vary in their initial trustworthiness (share rates: 20%, 35%, 65%, 80%) and will shift their behavior around the midpoint of the block to a new valence and level of certainty (e.g., from 80% to 35%). Participants' initial trust estimates, learning rates, and updating biases will be estimated using a modified Rescorla–Wagner update rule. To isolate socially-specific LDM, nonsocial parameters will be regressed out of corresponding social parameters, and the resulting values will be regressed onto HiTOP spectra. The goal of this exploratory study is to identify Social Computational Phenotypes (SCPs)—specific configurations of social learning parameters that correspond to locations within the HiTOP framework. These insights may inform future confirmatory work and improve detection and intervention in psychopathology.

Abstract Name: The Effect of Tightened Student Immigration Policy on Innovation Across Higher Education

Institutions in the United Kingdom

This project addresses how the United Kingdom's closure of the Post-Study Work visa (PSW) in 2012 and introduction of the Graduate visa in 2021 affected the number of international students in the country, as well as the contribution to innovation from higher education institutions (HEIs). Both the PSW and Graduate visa allow individuals holding a Student visa to remain in the UK for two years after graduation, without a work-sponsored visa. Ahmed and Davies (2025) discuss how reducing net inward migration to the UK was the motivation for the PSW closure. However, the economic impact on HEIs was not taken into consideration, and ultimately led to the introduction of the Graduate visa. Chellaraj et al. (2008) conclude that reducing the number of international graduate students in the United States through visa restrictions could significantly lessen innovation. My paper fills a gap in the literature by studying the immediate effects of the two policies, as well as the relationship between international students and innovation in the UK. I will be using a difference-in-differences approach for each policy. The control group is HEIs with a below median percentage of international students (during the base year). The treatment group is HEIs with an above median percentage of international students. The proxies for innovation are intellectual property revenue and number of patents granted by HEIs. Prior to studying innovation, the effect of both policies on the number of international students will also be observed. I expect to find that the closure of the PSW route decreased the number of international students across HEIs, and that this in turn decreased these institutions' contribution to innovation. The Graduate visa introduction, however, I expect to have increased the number of international students and the contribution to innovation from HEIs.

Abstract Name: Role of the Long Non-Coding RNA (LncRNA) CASC15 in Vascular Senescence and Disease

Cancer survivors are at increased risk for chronic kidney disease (CKD) as cancer therapies can activate the Renin-angiotensin system (RAS) and lead to end-stage renal disease and vascular dysfunction. Previous research has demonstrated the importance of long non-coding RNAs (lncRNAs) in regulating vascular cell dysfunction and senescence. Our lab has identified the lncRNA, cancer susceptibility candidate 15 (CASC15), and its association with two components of RAS: Angiotensin II and Angiotensin 1-7. Our lab is interested in the unknown effects of Angiotensin 1-7 on CASC15 expression. This project investigates whether CASC15 loss induces senescence-associated secretory phenotype (SASP) protein marker expression in mouse and human vascular smooth muscle cells (MVSMC, HVSMC), and whether this expression is altered by using Angiotensin 1-7. It is hypothesized that CASC15 will induce MVSMC senescence; this expression will be reversed with Angiotensin 1-7 treatment, and that such results will be reproducible in HVSMC. Using a series of western blots, we will detect common SASP protein biomarkers in samples of control, CASC15 knockout, and CASC15 knockout with Angiotensin 1-7 treatment for MVSMC and HVSMC. Notable results include that the SASP proteins HMGB1, p16, and γ H2AX, were the only tested proteins that were expressed in our samples, with expression levels increasing slightly in response to CASC15 knockout compared to control samples. Understanding how CASC15, RAS, and vascular cell senescence and dysfunction intertwine is crucial in establishing CASC15 as a potential therapeutic target for future CKD therapies.

Abstract Name: A Data-Driven Calibration and Visualization of the Quadratic Normal Volatility Model for EUR/USD

We propose a fully reproducible, data-driven calibration and visualization framework for the Quadratic Normal Volatility (QNV) model applied to the complete EUR/USD option surface. Motivated by decades-long empirical regularities—a persistent risk-reversal skew, short-term volatility turbulence, and a volatility minimum systematically displaced from the forward—the QNV model provides a fundamental specification using only three global parameters (quadratic curvature, base volatility, and minimum location). Leveraging the exact spectral characteristic function, we implement instantaneous pricing via the COS method and perform direct global least-squares calibration to a full volatility surface across strikes and tenors (quotes) with acquired Bloomberg data. Our core contribution is a visualization pipeline that integrates this calibration with high-resolution surface reconstruction and rich 3D visualizations of market vs. model smiles and residuals. This work visually tests whether a deterministic three-parameter model can match the fit quality of multi-factor stochastic models while offering transparency and computational speed for the world’s most liquid currency pair.

Abstract Name: Using Student Experience to Drive Course Co-design

How can courses be designed to best support the learning of every student? We addressed this question using Learning Experience Network Analysis (LENA) to analyze qualitative data from 84 student reflections of a co-design course. By mapping the co-occurrence of coded elements such as learner successes, struggles, and alignment with learning theories, this study was able to visualize these relationships and translate them into concrete course design changes. The analysis identified five different student learning profiles. For example, one group was motivated yet highly individualistic, so more formal project roles could be added to their course to reframe collaboration as an essential professional skill. Another group struggled with project pacing but excelled at engaging collaboratively, therefore adding more structure into the design process would be an apt design move. A third group felt less stress in the learning environment as they valued peer work, but struggled when dealing with irresponsible partners and team miscommunication. To support them, a “team charter” could be created to hold teammates accountable for team-set expectations regarding communication methods, meeting attendance, and division of labor. The final two profiles revealed students who struggled with procrastination and initial uncertainty, respectively. For them, design moves included introducing smaller, non-negotiable checkpoints and providing enhanced scaffolding materials to help them start. This cluster analysis and the design moves crafted from it showcase LENA’s strong application for developing learning environments that better honor student complexity.

Abstract Name: Resisting Toxins Made by Flesh-Eating Bacteria: Defining the Role of Annexin A2 Phosphorylation in Cellular Membrane Repair

Flesh-eating bacteria like *Streptococcus pyogenes* can destroy human tissue within hours, driven by toxins that puncture cell membranes. Failure to repair this damage causes cell death, tissue necrosis, and increased patient mortality. One strategy to reduce mortality is to improve tissue function by strengthening cellular membrane repair. The protein annexin A2 (A2) is a key mediator of this process, coordinating the rapid resealing of membranes after toxin attack. However, the molecular triggers that recruit A2 to sites of membrane damage remain poorly defined. In this study, we characterized A2's function in membrane repair after toxin exposure. We generated A2-knockout (KO) HeLa cell lines and challenged them with two cholesterol-dependent cytolysins: streptolysin O and perfringolysin O. Knockouts were validated by western blotting. Membrane damage was quantified by propidium iodide (PI) uptake and flow cytometry. Several independent A2-KO clones were tested. Clones displayed higher sensitivity to SLO and PFO exposure, with a significantly greater percentage of PI-positive cells than wild-type and other KO clones. These results indicate that, compared to the wild-type, the loss of A2 exacerbated toxin-induced membrane damage, suggesting A2 is critical for efficient resealing of membrane pores. This work highlights a key host-cell defense mechanism against bacterial virulence factors, bridging cell biology and infectious disease. By elucidating how annexin A2 helps protect cells from pore-forming toxins, our findings could inform strategies to mitigate tissue damage during bacterial infections. Ongoing experiments will examine whether reintroducing A2 (wild-type or phosphorylation-site mutants) can rescue the repair defect, to further dissect the molecular mechanism.

Abstract Name: Cataloging and Analyzing the Rector Paleoecology Lab's Non-Human Skeletal Collection: A Resource for Research, Education, and Comparative Study

Non-human mammal skeletal collections play a vital role in Biological Anthropology laboratories, serving as essential resources for teaching, comparative analysis, and the identification of skeletal remains. These collections allow students and researchers to develop skills in osteological analysis, species identification, and trauma assessment. A well-organized collection enhances the efficiency of skeletal comparisons and strengthens the effectiveness of educational instruction. Additionally, these collections provide valuable examples of skeletal trauma, which can manifest differently in non-human mammals compared to humans. Understanding these variations is crucial for forensic anthropology, zooarchaeology, and comparative anatomy studies, as it aids in distinguishing natural bone alterations from human-inflicted trauma. VCU's Rector Paleoecology Lab non-human skeletal collection consists primarily of specimens donated by hunters, resulting in a diverse array of traumatic injuries. These include antemortem, perimortem, and postmortem trauma, as well as evidence of blunt force impact, high-velocity projectile injuries, and pathological conditions. The presence of these varied traumas provides an opportunity for further analysis of bone healing, fracture patterns, and the effects of different types of force on skeletal structures. This study aims to systematically catalog, photograph, organize, and analyze the lab's collection to improve its accessibility and

research potential. By developing both physical and digital directories, this project will facilitate comparative research, aid in skeletal identification, and enhance educational opportunities for students and researchers. The resulting database will serve as a comprehensive reference, increasing the collection's utility in anthropological and forensic studies while ensuring its long-term preservation and accessibility.

Abstract Name: Dynamic Role Evolution in Multi-Agent Systems

The recent development of large language models (LLMs), such as ChatGPT and Google Gemini, have revolutionized the field of artificial intelligence, prompting for innovative ways to reach more advanced forms of intelligence. One approach that has shown much promise has been the advancement of multi-agent systems, which utilize multiple LLMs in specialized roles to tackle complex tasks. These teams of AI agents can outperform single models in organized environments. However, current architectures require fixed roles to be pre-assigned to each agent, making them rigid and prone to failures when placed in complex and dynamic environments, where tasks can change unexpectedly. Alongside this, systems tend to fall into infinite error loops when unable to complete a task. This results in an extreme waste of computational resources, inefficiencies in complex problem-solving, and lack of adaptation. This project proposes a novel multi-agent approach in which agents evolve their roles and adapt their strategies based on their environment. By shifting the paradigm from agents asking “what should I do?” to a more reflective “who should I become?”, agents can dynamically optimize collaboration and resource usage. This approach is tested in a simulated software development environment. A control group uses standard static role assignments with code-writing or reviewing agents, while the experimental group prompts agents to evolve roles based on performance feedback. We measure three outcomes: accuracy in solving complex coding problems, convergence speed (turns required to reach solution), and precision of the evolution mechanism activating in response to detected infinite error loops. We hypothesize that evolving systems will significantly reduce computational inefficiencies from error loops and improve problem-solving abilities when compared to static systems. Our results will establish a foundational mechanism and principle for self-organizing multi-agent systems with capabilities to tackle diverse, unpredictable challenges.

Abstract Name: Beyond Coursework: A Qualitative Study on the Unseen Burdens of First-Generation Immigrant and Refugee College Students

First-generation immigrant and refugee students face compounded challenges in higher education, including financial precarity, acculturative stress, and transnational obligations. Mainstream student success

frameworks often overlook the invisible labor these students perform, such as sending remittances, cross-border caregiving, family advocacy, and translation/interpretation work. These responsibilities increase stress and burnout and elevate the risk of academic attrition, yet their impact remains understudied. There is an opportunity for research to examine better how migration histories, socioeconomic hardship, and institutional inclusion or exclusion come together to shape the educational experiences of this population. This study presents preliminary findings from the qualitative phase of a larger mixed-methods study investigating how first-generation immigrant and refugee students navigate academic and transnational responsibilities. Semi-structured interviews were conducted with six undergraduate participants to document how they balance invisible labor with the demands of higher education. Data were analyzed thematically to identify patterns in family expectations, transitional challenges, bureaucratic barriers, and social support networks. Thematic analysis identified four central patterns influencing their academic trajectories. First, family expectations placed pressure on students to either excel academically and/or to provide significant financial support, often amid parents' limited familiarity with higher education. Second, students described transitional challenges from high school to college, including gaps in time management, study skills, and academic preparedness. Third, participants encountered bureaucratic barriers, noting that accessing institutional resources required substantial self-advocacy and navigating overwhelming and unfamiliar systems. Finally, social support through friendships emerged as a key source of emotional and academic resilience, particularly when students hesitated to share personal hardship with family. These findings highlight how transnational responsibilities intersect with structural barriers to shape student engagement. Qualitative insights generated here will inform the design of the study's subsequent quantitative phase and support efforts to develop more equitable, culturally responsive support systems for first-generation immigrant and refugee students.

Abstract Name: Relationship identification between triggers and electrophysiological changes in the brain and the overall human physiology during migraines

One of the most common neurological conditions in the world is migraines; nearly 1/4th of the working population suffers from this condition and exhibits a large variety of triggers. The current treatment method for migraine uses a few different medications for all migraines, regardless of triggers. Our hypothesis is that there is a specific relationship between the triggers of migraines and the electrical changes in the brain during migraines. The study incorporates two different data collection methods: electrophysiological tests (Electroencephalogram (EEG), Electrocardiogram (ECG), Galvanic Skin Response GSR, and a pulsometer) that record the unique electrical signals of the body and brain, and surveys that record daily exposures and experiences to extrapolate possible triggers. The participants will be 88 individuals from Embry-Riddle, comprising both men and women who experience migraines, with a ratio of men to women who experience migraines similar to the men-to-women ratio at ERAU. The large variety of data collected makes up for the low participant count and small population. Our preliminary results reveal a correlation between the triggers of "Allergies," "Anxiety/Stress," and "Dehydration" to the combined symptoms of "Aura and Minor Pain," "Aura," and "Aura, Major Pain, Fatigue, and Dizziness" respectively. The data also shows that generalized "Aura" is the most common symptom, and the most common trigger is "Allergies."

Abstract Name: Regulation of Wnt Signaling by Src-mediated Tyrosine Phosphorylation of LRP6 in Colorectal Cancer

Colorectal cancer (CRC) remains the second-leading cause of cancer-related deaths in the United States. A central driver of CRC initiation is dysregulation of the Wnt signaling pathway, often caused by mutations in the APC or β -catenin gene, resulting in constitutive signaling and uncontrolled cell proliferation. Proper pathway regulation depends on tightly coordinated phosphorylation events. Activation of the co-receptor LRP6 through serine phosphorylation is well characterized, yet the contribution of tyrosine phosphorylation remains unclear. Src, a non-receptor tyrosine kinase frequently overexpressed in CRC, has been implicated in modulating LRP6 activity, but its mechanistic role is unresolved. This study examines how Src-mediated tyrosine phosphorylation of LRP6 influences receptor function and downstream Wnt signaling. Tyrosine-to-phenylalanine LRP6 mutants were introduced into LRP5/6 double-knockout STF cells together with constitutively active or inactive Src variants, and subsequent receptor phosphorylation, endocytosis, and β -catenin activation were analyzed by western blotting, immunoprecipitation, and fluorescence microscopy. These findings define a Src-LRP6 signaling axis that couples tyrosine kinase activity to canonical Wnt activation, identifying a potential therapeutic target in colorectal cancer.

Abstract Name: Exploring the impact of two methane mitigation strategies on rumen microbiomes of grazing steers

Grazing steers partner with their rumen microbiomes to efficiently convert plant-derived carbohydrates into meat. Considering the socioeconomic importance of the beef industry, it is critical to develop strategies that maintain quality while lessening negative environmental impacts. Diet supplementation and hormonal implants have been shown to variably impact methane emissions and animal performance. A previous study looked at grazing steers across four treatment groups: diet supplemented, hormonal implanted, combined diet and implant, and no intervention. It found no significant impact of these treatments on methane emission nor animal performance over 90 days of grazing. However, the response of the rumen microbiome to such treatments remains relatively unknown. Here, we will analyze 16S and ITS rRNA gene amplicon sequencing from the same steers. We found that all treatments led to an increase in 16S and ITS alpha diversity over time, however, only the 16S diet group showed a significant increase in Shannon diversity. We did not see significant differences in the 16S or ITS composition of the rumen microbiome across treatments. However, there were significant alterations in both the 16S and ITS rumen microbiome composition over time. Future analyses will look deeper at individual microbial and fungal responses to diet and grazing time periods, as well as associations with methane and performance data. Ultimately, results from this study will provide insight into rumen microbiome dynamics during the life cycle of a grazing steer, further informing more sustainable management strategies.

Abstract Name: Enhancing Information Technology and Cybersecurity Student Communication Skills through Immersive AR/VR and AI-Driven Simulations Using VirtualSpeech

Advancements in immersive technology are creating new opportunities for improving communication skills in Information Technology and Cybersecurity education. This project explores the use of augmented and virtual reality (AR/VR) headsets combined with AI-driven simulations to help undergraduate students build confidence, reduce anxiety, and practice real-world communication skills. Using the VirtualSpeech platform, students were guided through scenarios where they presented security risk findings to an AI-driven avatar for realistic settings. These sessions were designed to replicate high-pressure professional environments, allowing students to practice quick thinking and technical communication in a safe and controlled setting. Fifty students from IT and Cybersecurity courses participated in the exercise, which includes Cyber 100, Security Risk and Analysis (SRA) 211, and Cyber 221. Before each simulation, students conducted a standard security risk analysis and prepared a brief presentation. They then entered an AR/VR environment where an AI avatar asked follow-up questions aligned with real Chief Information Officer expectations. Early findings suggest that students felt more confident speaking in stressful settings and found the immersive experience valuable for preparing for internships, presentations, and technical interviews. Many students also reported that AI-driven questioning helped them think more critically and communicate more clearly under pressure. Student researchers supported the design and delivery of these activities by managing the VirtualSpeech platform, uploading materials, and assisting participants throughout the simulations. While additional analysis is underway, initial feedback indicates that AR/VR technology and AI-generated interactions can play a meaningful role in communication training for technology-focused students. Future work will examine long-term skill development, expanded classroom use, and ways to increase accessibility for a broader range of learners can benefit from these immersive communication practices.

Abstract Name: Integrating Community Data and Satellite Data to Assess Air Quality across Richmond, VA

Addressing the serious environmental health issues associated with urban air pollution is limited by the spatial and temporal resolution of air quality data. This study integrates community-deployed PurpleAir PM_{2.5} sensors with MODIS-based Aerosol Optical Depth (AOD) imagery to examine seasonal and regional variability in air quality for Richmond, VA. Daily AOD retrievals at 1-km resolution were compared to PM_{2.5} measurements from more than 50 PurpleAir sensors, calibrated using EPA-derived correction equations and interpolated to a 1-km resolution using Empirical Bayesian Kriging. After normalization, these datasets provided a comprehensive framework for comparing surface-level PM_{2.5} concentrations with satellite-

estimated aerosol loading to assess whether AOD can serve as a proxy for PM_{2.5}. Seasonal and short-term analyses revealed that correlations between PM_{2.5} and AOD were consistently highest during summer, when both pollutant levels and variability increased. Periods of elevated pollution—including the Canadian wildfire smoke in Summer 2023—exhibited the strongest alignment between the two measures, indicating that AOD performs best as a proxy under poor air quality conditions. Spatial patterns across the city showed strong agreement between the PM_{2.5} and AOD measures for most of the city, with the Southeast neighborhoods, long affected by systemic underinvestment, having the higher levels of both PM_{2.5} and AOD, compared to Northwest neighborhoods. In contrast, central Richmond displayed notable mismatches between the datasets, especially in areas with heterogeneous land cover such as the boundary between Hollywood Cemetery and the working-class Oregon Hill neighborhood. By integrating low-cost sensor networks with satellite products, this study demonstrates the utility of combining community science with remote sensing to improve air quality monitoring in data-limited areas. The findings highlight both the potential and the limitations of AOD as a predictor of neighborhood-scale pollution and underscore the need for expanded sensor coverage in environmentally vulnerable communities.

Abstract Name: Engineering Bacteria for a Sustained Release of Mycosporine-like Amino Acid – Shinorine for Gut and Neurodegenerative Disorders

Shinorine, a UV-absorbing mycosporine-like amino acid, serves as a promising candidate for antioxidant and photoprotective applications. However, scalable production and delivery methods remain limited. Our recent work focuses on engineering *Escherichia coli* strains for shinorine biosynthesis, with tunable controlled expression. Using HPLC, we confirmed differential production levels, offering a suitable system for downstream applications. To explore delivery mechanisms, we evaluated the incorporation of shinorine into outer membrane vesicles (OMVs). These vesicles may serve as vehicles for topical or oral administration, enabling targeted access to skin or gut tissues with the aim of harnessing shinorine's antioxidant properties. Notably, animal studies revealed that orally or systemically administered shinorine was detectable in serum, gut, and brain tissue suggesting blood–brain barrier permeability. Collectively, these findings highlight shinorine as a bioactive compound of interest for translational applications and the potential of engineered bacterial platforms and OMVs in developing next-generation therapeutics.

Abstract Name: Female Agency in Works by Elizabeth Gaskell

In recent years Elizabeth Gaskell has become a more studied author for her depictions of class issues and female sexuality, especially by scholars such as Hilary Schor and Deirdre D'Albortis. These scholars look at Gaskell's works to find her transgressiveness, but female agency need not be limited to transgression. Within the context of Victorian Britain, Gaskell dared to write women as having independent control over their own lives in ways that strengthened their society as a whole for both women and men. In her novels *Mary Barton*,

Ruth, Sylvia's Lovers, and Wives and Daughters, Gaskell created heroines who are complex and are not fully obedient and selfless. Instead, her characters are empowered to make their own decisions and stand up for themselves and the people they care about. She offers a solution to the oppressive patriarchal systems of society in her texts in the form of communities of women, which allow for her heroines to become active agents and create a better society. Gaskell's depiction of agency is within the bounds of the private sphere, which saves her from accusations of political transgression, but even so her heroines make intentional choices to act. Her characters have agency in their own personal lives that come from the communities of women and from the lack of power the men have in the novels. Gaskell is giving her women agency so that they can cause a legacy of women who are able to have agency in reality. Gaskell is like her heroines, fighting through the conventions of women characters to give birth to new ideas surrounding gender and independence. Her works are embodiments of change and adding them to the canon of Victorian literature will allow for a more nuanced understanding of the past.

Abstract Name: Elucidating the Role of *Aedes albopictus* Hemocytes and Extracellular Vesicles in Dengue Virus Serotype 2 Dissemination and Amplification

Mosquito-borne viruses are a rapidly growing threat to public health, causing hundreds of millions of infections annually, with dengue virus (DENV) alone causing an estimated 100 million symptomatic cases and about 100,000 life-threatening cases yearly. With over half of the world's population now considered at risk, there is a need for new strategies to address the transmission of DENV. For DENV to be transmitted to a new host through the bite of a mosquito, DENV must disseminate from the initial site of infection in the gut to the mosquito's saliva, traversing physical barriers and evading the mosquito's immune responses. Currently, we lack an understanding of how DENV evades the mosquito's immune system and how it infects the salivary glands, events that are critical for viral replication and transmission. Preliminary studies suggest that mosquito immune cells, called hemocytes, are a key driver of viral dissemination through the production of extracellular vesicles. This project aims to assess DENV replication by mosquito hemocytes and the role of hemolymph extracellular vesicles (EVs) in DENV infection. Unraveling these objectives is key to understanding DENV dissemination after gut escape and is a necessary step in identifying targets to interrupt this process. In this study, we performed focus-forming assays on the supernatants of DENV-infected C6/36 cell lines that were exposed to varying concentrations of GW4869, an EV inhibitor, to quantify infectious viral particles. Additionally, we have conducted qPCR on the same supernatants to quantify the amount of viral genomes present. We expect to observe that the reduction in EV secretion of infected C6/36 cell lines will result in lower infectivity of virus secreted in the supernatant. Therefore, we expect the packaging into EVs to increase overall infectivity. These results would support that EVs may be a route of viral dissemination within mosquitoes.

Abstract Name: “If We Don’t, Who Will”: The New York Abortion Access Fund as a Defender of Reproductive Justice Post-Dobbs

Since Dobbs v. Jackson Women’s Health Organization which overturned Roe v. Wade and Planned Parenthood v. Casey, both of which allowed abortion to be federally protected, there has been a disconcerting increase in a lack of access to abortion on all fronts. Due to the mobilization and ongoing work of anti abortion movements, abortion funds have stepped in to fill the gap and provide access—yet there are still tensions around how this work shows up. This paper argues that by doing the ground work to destabilize any progress of reproductive rights, anti abortion movements have created the need for abortion funds which are now defending reproductive justice in this post-Dobbs era. Drawing from ethnographic research in Dr. McCaffrey’s ongoing project, this paper uses interviews of volunteers from the New York Abortion Access Fund (NYAAF) to give a closer look into how an abortion fund is actively defending reproductive justice.

Abstract Name: EEG Assessment of Varying Bilateral and Unilateral Musical Genre Stimulation on Human Neural Activity

Brain waves can be organized into frequency bands; Delta, Theta, Alpha, Beta, and Gamma, each stimulating different activity in the brain. Derivations in such electrophysiological activity can be measured non-invasively using electroencephalography (EEG) through sensors placed on the scalp. As auditory stimulus is altered, different neural regions are activated, influencing mood, performance, and perception. The previous study analyzed the effect of unilateral and bilateral WN on neural activity. Bilateral stimulation increased frontal lobe activity, demonstrating cognitive processing. Lateralized input showed frontal lobe activity and increased signals in parietal C3 and CZ EEG nodes, indicating restlessness. No stimulation showed restlessness and erratic frontal lobe activity. Based on the previous study with WN, further testing is in progress on different genres, which as literature shows, can prominently alter brain activity. The purpose is to determine the effect of different genres of bilateral and unilateral auditory input on brain activity. A 16-channel OpenBCI-EEG sensor is being used to collect data across a broad age range of participants experiencing controlled stimuli. A range of genres; particularly rock, Bollywood pop, classical, and ambient are being tested. It is worth noting that different genres generates unique stimulating factors for different people. As in the previous study, collected data is preprocessed using notch and bandpass filters to remove unwanted frequencies. Refined data is plotted through time series and Fast-Fourier Transforms, and compared in the form of topographical plots. These results are examined to determine whether auditory stimulation across genres is positioned as a prospective neuromodulatory tool. Full experimental results from the current study will be presented in the conference. Future investigation will generalize results and clarify whether variation in brain activity originates from genre or lateralization of input.

Abstract Name: Analysis of Directionals in Verbal Phrases: San Sebastián Coatán Chuj

This study investigates the structure and semantic contribution of directionals in positional and locative constructions in the San Sebastián Coatán dialect of Chuj. Previous work by Elias (2019) provides an in-depth analysis of these constructions; her work focuses exclusively on the San Mateo Ixtatán dialect and identifies a system of ten directionals used across positional and locative predicates. Extending this line of research, the present study examines whether the same morphosyntactic patterns and semantic contrasts hold in a less-documented dialect. Over the past several months, we have developed a corpus comprising over 1,000 isolated words and complete sentences through sustained elicitation sessions with a single native-language consultant. Preliminary findings indicate that the San Sebastián Coatán variety employs a smaller, and in some cases distinct, set of directional markers, suggesting dialectal variation in both the inventory and distribution of these markers. Prior work has shown an agglutinative system of directionals for forming detailed singular-verb phrases; these types of constructions appear to be unconstructable or unpreferred within the San Sebastián Coatán dialect. By analyzing our newly collected corpus, this study evaluates whether the reduced directional system in San Sebastián Coatán maintains this semantic contrast, providing new cross-dialectal evidence for the role of directionals in marking stage-level predicates.

Abstract Name: Effect of Leg Length on Drop Jump Performance

Drop jumps are commonly used in performance assessments as they allow insight into an athlete's reactive strength. Reactive strength is the ability of muscles to efficiently absorb force and then produce force again very quickly. It is evaluated using ground contact time, which refers to how long the feet stay on the ground during landing. The simple test of having a subject stand on a box, step off with their hands on their hips, land on both feet, and immediately jump, provides a controlled method for evaluating reactive strength. However, biological factors influence drop jump results. The research question guiding this study was whether leg length affects the relationship between ground contact time and jump height. Participants (ages 18-22) were ten male and female college athletes from a division III institution, including track and volleyball athletes. They completed two sessions of drop jumps from a 30 cm platform onto a force plate (CC Athletics, Odense, Denmark). Subjects completed fifteen jumps with ground contact times ranging from 0.15 s to 0.30 s. Leg length was measured from the Anterior Superior Iliac Spine to the medial malleolus. The round contact time duration, defined as the duration between the initial ground contact and takeoff, was quantified using force plate data. A linear regression analysis was conducted to investigate the effect of leg length on the relationship between ground contact time and jump height using Excel. We expect to find athletes with longer legs to exhibit a more rapid drop in jump height as ground contact time decreases. The results may highlight the importance of anthropometric measurements when interpreting reactive strength results. This research contributes to an understanding of how an individual's anatomical measurements affect their athletic performance. This may help inform more personalized approaches to strength and conditioning practices in the future.

Abstract Name: Derivatization of Alkyl-linked Isatin Dimers for Cholinesterase Inhibition

Acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) are enzymes that serve as potential drug targets for the treatment of neurodegenerative diseases. Inhibition of these enzymes has been shown to improve symptoms of diseases such as Alzheimer's Disease. Isatin has shown activity as an inhibitor of both AChE and BChE. The purpose of this study was to synthesize alkyl-linked isatin dimers, which show potential as effective inhibitors for both enzymes, and further derivatize these compounds to explore a structure-activity relationship. Isatin dimers with alkyl linkers ranging from 2-8 carbons were successfully synthesized, purified, and characterized via NMR spectroscopy. Two derivatization reactions are being investigated: condensation with hydrazine hydrate under microwave conditions and thionation with Lawesson's reagent. Preliminary results show the condensation with hydrazine hydrate was successful, but the reproducibility of the reaction was problematic. Optimization of the microwave procedure is currently in progress. The thionation reaction has provided complex mixtures that have proven difficult to purify, but several strategies to potentially address this issue have been identified. The full results of these ongoing synthetic investigations will be presented, along with inhibition data for successfully prepared compounds.

Abstract Name: Validating a Video-Based AI-Powered Early Autism Screening Web Application

Timely autism diagnosis remains a major public health challenge in the United States, where about one in 31 children is autistic and many are not identified until preschool or later. These delays are often linked to limited access to reliable screening tools and long-standing inequities that affect underserved and low-income families. To help address this gap, our work focuses on developing and validating iGAIT, a mobile-accessible screening application that uses computer vision and artificial intelligence to analyze gait patterns from short, parent-recorded videos for screening autism in children. Our validation process brings together several pieces: recruiting participants, supporting a fully remote video-submission workflow, and collecting detailed caregiver questionnaires that include demographic, behavioral, and medical information. To help more families participate, I created step-by-step video tutorials for completing the walking recording at home and designed recruitment materials that were shared across local community spaces. Another key part of this validation work involves comparing the AI-generated results with caregiver questionnaire scores. I automated the raw- and T-score calculations of the paper- and online- Social Responsiveness Scale (second edition) assessment by building a Python program that processes questionnaire data and produces standardized scores instantly, replacing the slow and error-prone manual method. This system allows us to check iGAIT's predictions more efficiently and with greater consistency. As we continue recruiting, we are actively testing both the AI model and the automated scoring workflow to understand how well the iGAIT application performs in real-world settings. Our goal is to fully validate this tool, so families have access to a fast, free, and more equitable option for early autism screening. By validating AI tools like iGAIT, this project helps promote earlier and more equitable autism detection.

Abstract Name: Don't judge a drink by its cover?: The influence of packaging on consumer perceptions of energy drinks

There is no shortage of research corroborating the importance of packaging in brand recognition and product positioning (e.g., Ghorbani & Westermann 2024; Orth & Malkewitz 2008; Singh et al. 2025; Underwood 2003). In exceptional cases, it can even affect significantly the perceived value of the product within it to a consumer, as the high resale prices of empty blue Tiffany jewelry boxes and Lululemon shopping bags, for example, have shown. This study investigates the feelings, emotions, and brand perceptions consumers receive from different types of packaging, specifically, in the product context of energy drinks. Using a phenomenological research framework, qualitative data collection in the form of semi-structured interviews, and grounded theory analysis techniques, emergent themes of student perceptions on the design of popular brands of energy drink cans were explored. Initial results revealed negative or positive emotions based on the graphics, colors, and size specifications of the cans, including effects on purchase intentions. Specifically, five main attributes of the packaging of energy drinks emerged as key determinants of consumer perceptions of brand positioning and purchase intentions: graphics, logo, colors, flavor depiction, and can size. This research reports and discusses each of these results, including implications for business practice and suggestions for future research.

Abstract Name: Movie-Star Miracle: Hedy Lamarr as a Hidden Figure in Science

Hedy Lamarr, heralded as one of the most beautiful women in the world, led a remarkable double life as a wartime inventor. Her life and legacy have touched the lives of everyone in the world today as her work became the basis for Bluetooth technologies. Despite her fame as an actress, knowledge about her technological contributions is lacking. This paper addresses the issue of female representation in science fields, and how a lack of knowledge about historical female inventors perpetuates prejudice against women in modern times. Bringing to light the worsening conditions faced by women entering scientific disciplines will put into perspective the injustice women face to this day. Using facts drawn from Hedy Lamarr's illustrious life as well as studies done on the workplace disparity between men and women, this paper aims to illustrate the importance of sharing the stories of women who have persevered in male-dominated fields. Hedy Lamarr remains a hidden figure in modern times, despite scientific genius. Her own face betrayed her as it overshadowed her technological achievements. This bias remains a problem in the scientific community and society of today.

Abstract Name: Fabrication and Surface Functionalization of AZ91D Gyroid Magnesium Scaffolds via Pressure Infiltration Casting for Enhanced Bone Regeneration

Magnesium alloys have gained increasing interest as biodegradable materials for orthopedic implants due to their bone-like mechanical properties and ability to resorb safely in the body. AZ91D, one of the most widely studied magnesium alloys, provides a balance of castability, biocompatibility, and corrosion behavior suitable for early-stage scaffold development. This project focuses on creating AZ91D gyroid-based tissue scaffolds using a novel mold-making approach that supports reliable casting of complex porous structures for bone regeneration. The fabrication process begins with 3D-printed molds designed to capture a gyroid architecture, chosen for its uniform stress distribution, interconnected porosity, and biomimetic stiffness. Initial molds printed with PLA and plaster-of-Paris negatives failed during sintering at 700 °C due to excessive thermal expansion, causing cracks and broken molds. To overcome this challenge, wax-enhanced PLA was introduced because of its negligible thermal expansion, enabling stable sintering and producing high-fidelity negatives. This improvement allowed successful pressure infiltration casting of AZ91D into intricate gyroid structures. Following casting, the scaffolds were characterized through SEM-EDS, XRD, and ICP-based chemical analysis to evaluate microstructure, phase distribution, and elemental stability. Biological testing included degradation studies and in-vitro assays such as MTT cell-proliferation, Live/Dead viability staining, and cell-attachment evaluation on the scaffold surfaces. Early results demonstrate consistent magnesium degradation profiles and promising cell adhesion on the fabricated AZ91D scaffolds, indicating their potential suitability for osteoconductive applications. This work establishes a practical and repeatable workflow for producing gyroid magnesium scaffolds using AZ91D through pressure infiltration casting and improved mold design. The findings contribute to the development of resorbable metallic implants that combine controlled degradation, structural integrity, and enhanced biological response for future orthopedic tissue-engineering applications.

Abstract Name: Methodologies to Obtain IV Characteristics for Various Systems: Project for the Thermo-Fluids Lab at SJSU

Measuring IV characteristics in controlled environments is increasingly important as renewable energy systems become more prominent. To support the ME115 Thermofluid Laboratory at SJSU, three experimental rigs were developed to analyze the IV behavior of the systems. The first rig used a centrifugal fan to drive a closed wind tunnel with a 4-inch test section and a total length of 3 feet, generating a steady wind speed of 15.83 m/s. A three-bladed rotor was placed in the test section and tested across resistive loads ranging from 100 to 9900 Ω . Voltage and current were measured simultaneously, and output power was calculated. The turbine exhibited a clear power peak near 100 Ω , producing 6.83 V, 69 mA, and 0.471 W. The second rig evaluated the IV characteristics of an 8 W EPV solar panel. Multimeters and a variable resistor spanning 0–10 Ω in 0.1 Ω increments were employed. Voltage, current, and power curves were generated, confirming the nonlinear behavior of the panel and its deviation from Ohm's law. In addition, a dielectric barrier discharge

(DBD) plasma torch was designed for measuring plasma input power. DBD plasma is highly capacitive, making its IV and power measurements challenging. A custom electrical circuit was developed for this experiment. The torch was operated at 10–15 kV/20–50 kHz using argon gas. Two 100 kV Bellet resistors and dual 1000:1 high-voltage probes were connected to an oscilloscope to analyze signal amplitudes and phase shifts between signals. From $V_{\text{peak-to-peak}}$, $I_{\text{peak-to-peak}}$, and the phase shift, plasma power was measured between 15 to 40 mW at the operating conditions set for this experiment. Comparing these three systems highlights the diverse approaches required to accurately capture IV characteristics across mechanical, solar, and plasma-based technologies. Full experimental results will be presented at the conference.

Abstract Name: The Sacred and the Spectacle: Islamic Architecture in the UAE Today

In the United Arab Emirates (UAE) sacred architecture rises within a landscape shaped by global capital. Mosques in Dubai and Abu Dhabi now bear the signs of Western architectural sophistication; modern square and rectangular buildings in monochrome, concerned with sustainability and energy efficiency, all while paying homage to the contemplative nature of old Islamic architecture. This project investigates how contemporary architects in the UAE navigate the tension between the visual language of global capitalism and the foundational principles of Islamic architecture. Even as major cities in the UAE including Dubai and Abu Dhabi expand through monumental icons and other aesthetic markers of global capital, their sacred buildings continue to draw upon Islamic principles grounded in geometry, proportion, and a transformative spiritual atmosphere. Together, these conditions raise questions about how spectacle-driven, internationally-oriented design and spiritually rooted architectural traditions coexist, collide, or quietly reshape one another within the UAE's rapidly developing urban environment. This project analyzes three recent religious sites: the Majid Al Futtaim Mosque and the Mosque of Light in Dubai, and the Abrahamic Family House in Abu Dhabi. These buildings offer distinct approaches to Islamic architectural identity, from minimalism and filtered light to pure geometric expression and interfaith spatial dialogue. Together, they reveal how Islamic sacred space in the UAE is no longer defined by ornamental motifs or historical replication but by conceptual reinterpretation and the negotiation of cultural meaning within a modern cityscape. The expected findings suggest that rather than being overshadowed by global capitalist aesthetics, Islamic architecture in the UAE is evolving through subtle spatial strategies that preserve spiritual essence while engaging with contemporary urban conditions. This project contributes to broader discussions on architectural identity and cultural expression in the 21st century, offering insight into how religious architecture adapts, and sometimes resists, within cities shaped by global ambition.

Abstract Name: Prevalence of ADHD and Autism in Community Colleges

Although public awareness about Attention Deficit Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder (ASD) is growing, research on the prevalence of ADHD and ASD at community colleges (CCs) is sparse. CCs serve diverse and often underserved students, many of whom may have undiagnosed ADHD or ASD due to financial barriers, cultural stigmas, or lack of early support. Traditional methods of estimating the prevalence of ADHD and ASD in CCs (e.g., using general population statistics or convenience sampling) likely misrepresent the true number of students with these conditions. This study scientifically assessed the prevalence of ADHD and ASD among CC students using validated screening methods. By improving screening methods of ADHD and ASD, CCs can better serve their diverse student populations. Because of limited access to healthcare, socioeconomic barriers, cultural stigmas, and masking behaviors—particularly among historically underrepresented and nontraditional student populations, we expect the prevalence of ADHD and ASD traits among CC students to be significantly higher than the prevalence of ADHD and ASD in the general population. Further, for the same stated reasons, we expect formal diagnoses of ADHD and ASD in CC students to be lower than those found in the general population.

Abstract Name: Compactification and Quantum Mechanics of Quadratic Normal Volatility

This research establishes that the risk-neutral Quadratic Normal Volatility (QNV) model with a trigonometric discriminant is probabilistically and spectrally equivalent to free quantum mechanics on a compact one-dimensional Riemannian manifold of constant positive curvature. The arctan transformation compactifies the real price line onto an open interval, pulling back the volatility-induced metric to the round metric of curvature. The Lamperti transform followed by the exact ground-state similarity reduces the pricing operator to the free Laplacian up to a constant shift. Consequently, European option prices and the characteristic function of log-price admit explicit Fourier sine series on the circle, with eigenvalues and sub-exponential truncation error. The volatility smile arises purely from the positive curvature of the price manifold, with smile depth strictly increasing in our chosen parameter. The model is therefore the unique specification of local volatility with a transition mechanism that is exactly solvable free diffusion on a compact space of constant curvature.

Abstract Name: Differential Optical Absorption Spectrometer for Altitude-dependent Greenhouse Gas Concentration Characterization

Analyzing the changing chemical composition of the lower atmosphere is becoming increasingly pertinent to monitoring the health of the planet as the impact of climate change and global warming becomes progressively more drastic. Developing methods of characterizing greenhouse gas concentration is thus an important priority in atmospheric science. An effective technique for remotely measuring the concentration of a particular chemical in a gas sample is differential optical absorption spectroscopy (DOAS), which, in the

mid infrared portion of the electromagnetic spectrum, utilizes the absorption bands corresponding to a molecule's vibrational transition frequencies to distinguish it from the background. Carbon dioxide (CO₂) and methane (CH₄) are ubiquitous greenhouse gases with well-defined mid-infrared absorption wavelengths. Mid-infrared DOAS is performed for these molecules using a photodetector by comparing the incident light intensity at the absorption frequency to that of a non-absorptive reference frequency. Here, an instrument that utilizes mid-infrared DOAS to characterize CO₂ and CH₄ concentration in the lower atmosphere with respect to altitude is designed and constructed for integration onto a model sounding rocket. A pair of thermophile detectors are connected to a printed circuit board and a microcontroller; the assembly amplifies and interprets the electrical signal for analysis after flight, as well as records other data, such as temperature, barometric pressure, and humidity, that are important in calculating gas concentration. An initial prototype employs passive DOAS, which measures ambient atmospheric infrared transmission via a specialized ceramic glass nosecone tip. This novel methodology shows promise for generating gas concentration profiles up to 2 km.

Abstract Name: Preventing Rejection in Liver Transplant Recipients

Background: Over four million people are diagnosed with chronic liver disease in the US each year. This is a fatal diagnosis if a liver transplant is not performed. Transplantation is a procedure that has many risks associated. It requires immediate lifestyle changes and lifelong medication adherence. Transplant recipients may stop taking their medications for reasons such as unpleasant side effects or financial strain. They may also continue to drink alcohol after receiving their transplant due to untreated alcohol use disorder. Recipients who make poor health decisions due to lack of education or mental health treatment instead of following their required care plan can develop complications that lead to organ rejection and death. Aim: The aim of this study is to investigate nursing interventions to prevent liver transplant rejection. Method: The incorporation of psychosocial screening tools alongside addiction treatment for those on liver transplant waiting lists will be implemented to determine any significance in decreased rates of alcohol relapse. Conclusion: Providing comprehensive education on medication side effects will improve patient adherence to immunosuppressants. Obtaining access to healthcare resources and an adequate support system provides transplant recipients with the assistance needed to recover from their procedure at home. Those who accomplished a period of sobriety have been found to be less likely to return to drinking alcohol. Receiving a psychological evaluation is proven to predict rates of alcohol relapse in recovering addicts who receive a liver transplant. Receiving mental health and addiction treatment post-transplant also improved recovery rates. More research is needed to understand whether receiving both mental health and addiction services before transplantation will promote recovery and prevent alcohol relapses.

Abstract Name: Effects of Multi-Species Plantings on Dune Grass Survivability and Growth

Coastal ecosystems protect natural and human infrastructure from environmental disturbances exacerbated by climate change and anthropogenic influences. Sand dunes play a critical role in these areas by reducing flooding, buffering wave energy, and preventing erosion. Unfortunately, these beneficial structures are being lost at an increasing rate due to development in coastal landscapes and more intense weather events. Restoration plantings are a solution to maintain our remaining dunes and facilitate the growth of new ones; however, a knowledge gap exists regarding how these plants interact with one another, posing a challenge for restoration efforts. Our objective for this study is to determine how multi-species plantings affect the survivability and growth of four common dune grasses found on the coast of the eastern U.S.: *Ammophila breviligulata*, *Panicum amarum*, *Spartina patens*, and *Uniola paniculata*. These grasses were grown in mono-, bi-, or tri-cultured pots, with six plants per pot and 60 pots in total in a mesocosm study. Grasses were grown at the Rice River Center for 12 weeks, with data collected at the beginning, middle, and end of the experiment. Analysis of the collected data on stem density, species survival, surface leaf area, leaf length, aboveground biomass, and plant height is ongoing and will be used to draw conclusions about growth based on treatment. These conclusions will better inform management and restoration efforts.

Abstract Name: Histopathologic Impact of a Periodontal pathogen on Colorectal Cancer

Emerging evidence links chronic periodontal infection to systemic diseases, including colorectal carcinoma (CRC). The keystone periodontal pathogen, *Porphyromonas gingivalis* (Pg), has been detected inside colorectal tumors, but its mechanistic role in cancer progression remains unclear. This study established a novel orthotopic CRC mouse model with systemic Pg infection to evaluate tumor histopathologic changes. To examine the effects in vivo, C57BL/6 mice were orthotopically injected in the rectum with MC38 CRC cells and subsequently infected intravenously with Pg (1×10^7 CFU) or PBS control three times post-tumor implantation. Tumor growth was monitored by serial computed tomography (CT) scans. Tumor sections were analyzed histologically to assess Pg-induced changes in tissue architecture. In mice, repeated Pg exposure led to accelerated and larger tumor growth compared to tumor-only controls. Histological analysis indicated altered tumor structure in Pg-infected groups. The Pg-infected groups showed increased necrosis compared to the non-infected groups. The Pg-infected groups exhibited lymphovascular invasion (LVI), potentially suggesting lymph node metastasis indicating CRC systemic invasion and spread. Furthermore, although typical CRC adenocarcinomas are epithelial cells, the Pg-infected groups showed presence of spindle-like cells, possibly suggesting sarcoma development. The results also showed evidence of tumor migration up into the colon despite being originally injected into the anal canal. Our findings demonstrate that chronic Pg infection enhances colorectal tumor growth. The presence of LVI and possible lymph node metastasis could signify a more advanced stage and worse prognosis of CRC. These results suggest that Pg plays a critical role in colorectal cancer progression and may represent a potential microbial target for prevention and therapy.

Abstract Name: Evaluating Hybrid Photovoltaic-Thermal Systems: The Impact of Dual Energy Harvesting on Renewable System Efficiency

Reliable and sustainable energy access remains a global challenge, especially in underserved regions where infrastructure is limited and dependence on fossil fuels persists. This project investigates a hybrid photovoltaic-thermal (PV/T) system designed to simultaneously generate electricity and recover thermal energy from solar radiation. The central research question explores how integrated energy harvesting can improve overall system efficiency, reliability, and sustainability compared to conventional photovoltaic modules. To address this, a prototype PV/T system was constructed using embedded sensors to monitor electrical output, panel temperature, solar irradiance, and heat recovery. Experiments were conducted under varying environmental conditions to evaluate the impact of cooling methods, material selection, and system configuration on performance. The thermal integration component included a copper coil and circulating water loop to extract excess heat from the panel surface. Data analysis revealed that this thermal regulation stabilized panel temperature, preserved voltage levels, and enabled dual energy harvesting, resulting in improved energy utilization. The results demonstrate that hybrid PV/T systems can significantly enhance energy output while reducing greenhouse gas emissions and minimizing wasted thermal energy. This approach is particularly beneficial for Sub-Saharan communities, where reliable energy access can support water purification, healthcare delivery, and educational infrastructure. By linking technical innovation with environmental stewardship and social responsibility, this research contributes to the development of resilient and sustainable energy solutions tailored to real-world conditions. Ultimately, the findings serve as a foundation for future system improvements and highlight the potential of hybrid renewable technologies to address global energy challenges through localized, efficient, and scalable solutions.

Abstract Name: Beneath The Surface: Exploring the Interplay of Parent-Child Relationships, The Big Five Personality Traits, and Self-Esteem in Young Adults

Introduction: Research on the interplay between parenting, personality, and self-esteem in young adults is scarce. Thus, this study assessed whether supportive parenting characterized by warmth, structure (e.g., clear expectations), and autonomy support would be positively correlated with self-esteem (e.g., self-evaluation) and Big Five Personality Traits, including extraversion (e.g., sociability), conscientiousness (e.g., goal-orientation), agreeableness (e.g., kindness), openness, and emotional stability. Personality traits were expected to positively correlate with self-esteem. Additionally, parent-child relationships were expected to predict self-esteem when controlling for personality. Methods: Participants were recruited via Middle Tennessee State University's Psychology Research Pool, Honors College, and the Undergraduate Research Center. A questionnaire was administered, including the Rosenberg Self-Esteem Scale, Big Five Personality Trait Test, Network of Relationships Inventory, and Parents As Social Context Questionnaire (to assess parenting). Results: 311 participants were recruited, primarily female (76.3%) and 18-25 years old (97.4%). Parental warmth ($r = .15$) and autonomy support ($r = .24$) were found to be significantly positively correlated with extraversion. Parental warmth ($r = .20$), structure ($r = .21$), and autonomy support ($r = .29$) were correlated with emotional stability. Warmth ($r = .34$), autonomy support ($r = .40$), and structure ($r = .31$) were

positively correlated with self-esteem. Parental support in parent-child interaction was linked to agreeableness ($r = .20$), extraversion ($r = .19$), and self-esteem ($r = .29$). Personality traits, including extraversion ($r = .53$), conscientiousness ($r = .25$), and emotional stability ($r = .54$), were correlated with self-esteem. Emotional stability ($\beta = .37$), conscientiousness ($\beta = .20$), and extraversion ($\beta = .39$) significantly predicted self-esteem. Conclusion: As expected, parental support, warmth, structure, and autonomy support were positively correlated with self-esteem. Positive parenting and parental support were correlated with the Big Five Personality Traits. In the regression model, extraversion, conscientiousness, and emotional stability predicted higher self-esteem. Unexpectedly, parent-child relationships did not predict self-esteem when controlling for personality traits.

Abstract Name: AI-Driven Analysis of Diversely Sized Martian Geological Features with Deep Learning

The MRO HiRISE (Mars Reconnaissance Orbiter – High Resolution Imaging Science Experiment) instrument provides some of the most detailed images ever captured of the Martian surface, making them ideal candidates for advanced image-recognition AI. However, their high resolution and wide variation in feature scale pose major obstacles. Standard preprocessing techniques, such as padding or rescaling, either erase fine details or make images too large to process efficiently. This research directly addresses these challenges by developing an effective method for detecting specific Martian geological features within HiRISE imagery. I implemented a tiling workflow paired with YOLO-based object detection models, enabling the system to locate targeted features that would otherwise be missed using conventional approaches. A significant challenge arose in evaluating the detections. Existing ground-truth labels capture only a fraction of the actual features, and the model's bounding boxes often vary in size and overlap extensively, especially when features do not fit cleanly within a single box. As a result, traditional metrics like Mean Average Precision proved insufficient for characterizing model performance. To overcome this, I introduced a secondary validation process using deep learning-based image classification models to assess detections beyond what conventional metrics can measure. This dual-layer evaluation framework provides a more meaningful and accurate picture of the model's capabilities. Together, these contributions support more reliable, scalable analysis of planetary surfaces and open new pathways for future AI-driven exploration.

Abstract Name: Dissolved Oxygen and Chlorophyll-a: An analysis of water quality in the Snohomish River located near a local farming complex

Dissolved oxygen and Chlorophyll are two important parameters used in measuring water quality in aquatic habitats. Numerous factors can influence water quality. Nutrient runoff from farming communities can play an important role in a body of waters' quality. Excess nutrient runoff such as phosphorus and nitrogen can increase decomposition within the water, increasing algae blooms, and excess algae decomposition can in

turn increase bacterial growth. Both algae and bacteria consume surrounding dissolved oxygen and influence the balance of the ecosystem's life sustaining oxygen levels. We conducted a point-in-time analysis of both the dissolved oxygen levels and chlorophyll-A for a comparison of a backwater runoff near a farming complex, an upstream analysis to evaluate the river's levels before the farming complex, and samples to analyze to see if there was an impact downstream. We identified no statistically significant differences between sample locations. An average of the samples taken at our three locations showed well above desired dissolved oxygen levels within each sample location having a mean > 10 ppm and Chlorophyll-A levels at each site at ~ 3 ppb indicating an mesotrophic river, and an overall healthy aquatic environment.

Abstract Name: The Compendium of Castbelow Aberrations: Magical Qualities of the Multiplicitous Real

Fantasy is seductive. It writhes like the ever-shifting castle chambers of a person's perception and identity; given that perception is reality, in its deviation from what is "real," fantasy nonetheless subsumes the real. Realistic modes of storytelling, on the other hand (nonfiction, realist fiction, news, etc.), often assign artificial structure to events without taking the influence of imagination on experience into account. Scholars have wondered at the mystical quality of imagination extensively. The Compendium of Castbelow Aberrations, a multimodal hybrid of art and literature made physical, investigates the power of fantastical modes in this tradition, informed by concepts such as: the object's activation of critical thinking (Kristeva); magical Umwelten (Uexkull); the suspension of disbelief (Coleridge); and the deviations between person, player, and persona (Waskul and Lust). This presentation will cover how the Compendium's very narrative reflects its inspirations; the narrator embarks on a reality-bending journey through a ruinous desert to discover how and why the destructive Flare occurred, and what horror it has done to the magical atmosphere. His investigation into the now-unfamiliar magics of his homeland recontextualizes the typicalities he understood before, allowing him to become a better spellcaster at an unknown expense; he is changed by a new, impossible circumstance that doesn't adhere to the rules he knows. Furthermore, his story has been woven collaboratively through TTRPG (Tabletop Roleplaying Game), not in a vacuum; his environment history, relationships, and discoveries have been and will be shaped further by fellow participants - fellow castles of perception - in an ever-murmuring tale that mirrors and informs the contours of reality itself.

Abstract Name: The Timeless Economy: Beyond-Era Exchange Between Actor and Audience

Informed by the general economy of Georges Bataille, Kathleen McCormick's work on reader reception, and Martha Nussbaum's perceived "humanistic aspects of science," this essay argues that, by recognizing econoliterary parallels theorists might be able to glean new insights from stories that hugely predate the modern reader, providing a foundation by which to make them relevant without relying on often flatulent reinterpretations. Literature and economic theory share a tendency to generalize in order to pursue themes or ideals. In other words, both simplify variables in order to support postulations about the supposed universal tendencies of the macrocosmic order (that is: all that subsumes the social, environmental, natural micro

orders, etc.). Because of their shared normative inclinations, both disciplines mirror each other. They can, therefore, interloquite - share syntax. Through what I call a lens of current-cy," literary analysis becomes timeless; literature remains relevant. Informed by the 2035 iteration of the Stratford Theatre Festival, hosted in Stratford, Ontario, which was very liberal in its reiterations of classic tales, this presentation magnifies Anne of Green Gables, written by L. L. Montgomery and adapted by Kat Sandler; and The Winter's Tale, written by William Shakespeare and directed by Antoni Cimolino in particular, which take very different interpretive approaches. However, these differences are not to their detriment; they allow me to describe what makes an effective reinterpretation under the disciplinary mode of economic theory. Together, reinterpretation and theories of exchange can coexist and enhance each other, if only they might glance in the mirror.

Abstract Name: Developing an Instrument to Assess Adolescent Autonomy in Asthma Self-Management Behaviors

Introduction: Asthma is a significant public health problem, with a prevalence of 8.4% among adolescents. Adolescents' cognitive and developmental characteristics differ from children and adults, yet few self-reported asthma measures exist for this group. A recent systematic review found reliable questionnaires for asthma knowledge, self-efficacy, control, and quality of life, but none focused on adolescent asthma self-management. Purpose: The aim of this study is to develop and validate an asthma self-management instrument for adolescents (12–21 years) using systematic, seven-step published guidelines. Objective: The objective is to develop and validate an instrument to assess adolescent asthma self-management behaviors, including item development, evaluation of content and face validity, and testing of psychometric properties. Method: A community-based participatory research approach was used to ensure survey items were clear, relevant, and meaningful. Initial collaboration involved three adolescents who co-developed content with investigators. Feedback from ten additional adolescents (mean age 16.8) informed revisions. Content validity was reviewed by 17 content experts in allergy, pulmonology, behavioral science, nursing, and school health. Psychometric testing of the tool is ongoing. Results: Forty-one items were developed from literature and prior qualitative findings on adolescents' self-management. Domains included symptom prevention, acute management, communication, and goal setting. Expert review led to three deletions, three revisions, and high ratings for clarity (mean = 8.5) and relevance (mean = 8.7). Conclusion: This is the first validated self-report instrument addressing adolescents' autonomy in asthma self-management. By clarifying age-relevant responsibilities, it enables tailored strategies to support autonomy and long-term control. The instrument will address a critical gap and guide nurses and researchers in designing interventions, tracking behaviors, and improving outcomes, as well as reinforcing nursing's role in promoting autonomy and developmental care.

Abstract Name: Reclaiming the Political Future of the Sahel Through the Rejection of French Influence

Beginning in 2021, three Sahelian states—Mali, Burkina Faso, and Niger—staged three successive military coups in an attempt to move towards self-determination. As a result of French exploitation and continued neo-colonial influence, these nations seek to redefine their political trajectory for true independence through the newly formed Alliance of the Sahel States (AES). This study investigates the motivations behind the rejection of French interventionism and the conditions that led to the creation of the AES. Drawing on close reading of recent literature by leading scholars and political analyses, I synthesize critical findings to illustrate the historical and geopolitical context in which the AES arose. Preliminary results reveal that France's continued and persistent presence in post-independent Africa is widely regarded as a continuation of exploitation and unequal power dynamics. As a result, these Sahelian states have rejected French influence under their new military regimes by promoting their native languages, initiating and enacting the withdrawal of French military troops from Sahelian soil, and installing governments with explicitly anti-France agendas. Collectively, these developments illustrate a broader effort to establish genuine self-governance rooted in local values, languages, and economic autonomy. This research study offers a deeper critical analysis and understanding of contemporary French neo-colonialism, interventionism, and exploitation within the context of geopolitical realignments in former African colonies.

Abstract Name: Do Temporary Mood States Influence the Alliance Ratings Made by Clients with Depression?

Working alliance—the relationship between client and therapist—has a bidirectional positive correlation with client outcomes. A previous study failed to detect an impact of mood on alliance ratings but suggested the need for further research with depression, given the relevance of mood for depression. The purpose of this study was to test whether mood states of depressed clients contribute their alliance perceptions. The study employed an experimental manipulation of mood prior to measuring alliance. It was hypothesized that participants in the positive mood condition would rate the therapeutic alliance with their therapist higher relative to participants in the negative mood condition. Participants were randomly assigned to view a brief movie clip in either the positive mood condition or negative mood condition, then completed a mood state measure, followed by an alliance questionnaire about their current therapist, demographics and therapy characteristic questions, and a depression questionnaire. A series of independent samples t-test revealed successful manipulation of negative mood; however, positive mood ratings did not significantly differ between conditions. There was also no statistically significant difference for the alliance total or subscale scores between conditions. A Pearson's correlation revealed a statistically significant negative correlation between the total depression scores and alliance scores. Alliance scores did not appear to differ between conditions for clients who had clinically significant depression scores. Clients with sub-threshold depression had higher alliance scores in the positive condition compared to the negative condition with a small effect which did not reach statistical significance. One explanation for the findings is that alliance ratings are not biased by temporary mood states in depressed clients, perhaps suggesting clinicians can be confident in alliance ratings in depressed clients. Alternatively, the results may be affected by a small sample size. Future research might consider changes to stimulus materials and inclusion criteria around suicidality.

Abstract Name: Investigating gene expression changes in the brain reward circuitry following fentanyl self-administration in mice.

Opioid addiction is a rampant issue in the United States with millions of people misusing opioids every year. More than 70 thousand people each year are victims of fatal opioid-related overdoses and synthetic opioids, predominantly fentanyl, are responsible for roughly 80% of those deaths. Assessing gene expression changes helps to uncover biological mechanisms that outline addiction. However, transcriptional research has been studied in opioid addiction but primarily in the context of morphine. Prior research in the Lefevre lab has shown that non-contingent morphine administration increases gene expression of heat shock proteins within the brain reward circuitry, specifically the nucleus accumbens and dorsal striatum. Here, I tested the hypothesis that contingent self-administration of fentanyl would evoke similar changes in the nucleus accumbens and cerebellum. The mice received a jugular catheter implant, then the mice went through the self-administration paradigm designed by the Lefevre Lab. Brain samples were collected 24 hours after self-administration was finished. RT-qPCR was then carried out to measure gene expression of Hspa5 and Hspb1. Mice that underwent fentanyl self-administration successfully distinguished between active and inactive levers across the 10 day paradigm ($p < 0.05$). Hspa5 gene expression was found to be downregulated in both the nucleus accumbens and the cerebellum ($p < 0.05$), while Hspb1 was downregulated in the nucleus accumbens ($p < 0.05$) but not in the cerebellum. These preliminary results of heat shock protein expression following fentanyl self-administration in the nucleus accumbens and cerebellum show opposite regulation patterns compared to non-contingent morphine administration.

Abstract Name: "The Half-Heathen State to Which I See so Many Irish Girls Reduced Here": The Irish American Girl in Post-Famine American Print

1845 marked the first year of the Irish Potato Famine, plaguing the island with severe economic, personal, and physical loss. The Famine persisted for eight years, trademarked by failing potato crops combined with a distinct lack of aid, empathy, and action from the English government. In the immediate years following the Famine, the United States of America experienced a large influx of Irish American immigrants looking for refuge from these failing crops and English interventions; specifically, young, unmarried, and relatively poor Irish women. Because of the large influx of Irish immigrants, stereotypes regarding Irish Catholicism, work ethic, and education began to spread through the 19th century American social fabric. My research analyzes the literary trends and rhetoric of 19th century American print in relation to Irish and Irish American women and girls. Sentiments like "no Irish need apply" were open and accepted viewpoints held by multi-generational Americans. Irish American women were not immune to stereotypical labeling; in fact, because of their disproportionately high immigration rates, they suffered equally, if not more, the same fates as Irish American men. With the analysis of multiple genres of post-Famine American literature, such as news reports from the Brother Jonathan magazine, articles explaining Irish intellectual capabilities in The Ladies'

Keepsake, and Home Library, and the novel Bessy Conway; or, The Irish girl In America by Mrs. J. Sadlier, I conclude that anti-Irish stereotypes and ideas, specifically regarding Irish American women and girls, were created and perpetuated through 19th century American print culture.

Abstract Name: Let's Talk About Sex: The Intimate Relationships Between Women Religious and Christ in Medieval Europe

Throughout medieval Europe, there were no shortages of women religious. From English anchoresses such as Julian of Norwich to Italian Dominicans like St. Catherine of Siena, holy Christian women – such as abbesses, anchoresses, nuns, and devoted lay women– were scattered throughout and beyond the continent. My research, interdisciplinary in nature, analyzes the trends, themes, and imagery found in the Vitas (written works detailing a saint's life), writings, and personal works of medieval women religious. Specifically, I aim to highlight the abundant instances of sexual, intimate, and transcendent relationships between medieval women religious and Christ within their unique historical context. While my research is ongoing, the early analysis of primary sources from (or relating to) St. Catherine of Siena, St. Ida of Ireland, Julian of Norwich, and Margery Kempe has indicated that the complex and common occurrences of intimacy with Christ (in relation to women religious) reflect and adhere to the teachings found in St. Augustine of Hippo's *The Excellence of Marriage and Holy Virginit*y. In these texts, St. Augustine outlines different purposes for sex within married couples, as well as defining the different nature between every human's physical and spiritual purity. Ultimately, medieval women religious were spiritually authorized to have metaphysical relationships with Christ because of church teachings on sex within marriage and their physical choice of religious devotion.

Abstract Name: The Megachurch as an Idol

Megachurches in the United States draw massive crowds, bring in swaths of wealth, and are the locations of many controversies within and outside of the Christian faith. As demonstrated by two theologically divergent megachurches, Lakewood Church run by the Osteen family and First Baptist Church of Dallas lead by Robert Jeffress, the growth and current state of these megachurches is preeminently built upon the marriage of the American Dream and Christianity: resulting in overt or subtextual prosperity theology elements. The rise in Christian book and music industries, and advertising/marketing of products within the church are examples of these elements. Overt or not, both Lakewood Church, with outright prosperity gospel teachings, and First Baptist Church of Dallas, with intense Christian nationalism, lead their followers through flawed ideologies and monetized spiritual practices that promote and constitute idolatry.

Abstract Name: Design, Fabrication, and Raindrop-Induced Characterization of PVDF Films and Custom 3D-Printed PZT Composite Piezoelectric Materials

Environmentally driven energy harvesting offers a way to develop self-powered sensors and low power electronics that can be utilized in remote or hard to maintain environments. Rainfall is an underdeveloped energy source that produces frequent and low energy output. The purpose of this project is to evaluate if additively manufactured PZT composites can serve as effective piezoelectric materials for harvesting energy from raindrop excitation as few studies have directly analyzed this. This project evaluates the electrical response of PVDF films and custom SLA 3D-printed PZT composite samples subjected to controlled droplets. To compare the materials and evaluate droplet efficiency, a complete droplet impact testing system was designed and fabricated. The apparatus consists of a 5' adjustable 80/20 aluminum extrusion with modular 3D-printed mounts and a laboratory burette to produce identical droplets. Force and voltage data was collected using a NI-9234 data acquisition module connected to LabVIEW 2025, which allows the ability to record each impact event and export as a CSV to be further processed in MATLAB. 3D-printed PZT composites were fabricated, wired, and along with a PVDF sample, mounted onto the apparatus and tested at multiple heights. Early findings show that both force and voltage output increase with droplet height for all materials. The additively manufactured PZT composites exhibit a high potential for electrical output which is influenced by the percent volume of PZT added to the photopolymer and variable geometry. Their performance suggests that additive manufacturing may serve as a viable route for tuning material composition and geometry for unique energy harvesting needs. Overall, this project establishes a highly repeatable droplet excitation and measurement system and provides initial comparisons between various custom 3D-printed PZT composites. It further identifies the potential use for highly customizable 3D-printed piezoelectric composites to be used in low energy sensor and monitoring environments.

Abstract Name: Impact of Parental Presence on the Quality and Quantity of Language Exposure on Preterm infants in the NICU

Each day a fetus remains in utero is beneficial for growth and neurodevelopment, reducing the risk of medical complications. However, preterm birth may be medically necessary or occur without warning, requiring specialized care in the Neonatal Intensive Care Unit (NICU). Preterm birth has been correlated with poorer neurodevelopmental outcomes when compared to term infants. We understand cognitive development and language acquisition begins well before birth and continues through adolescence. This study explores the impact of parental presence on the quantity and quality of language exposure that preterm infants receive in the NICU, based on visitation patterns and speech type directed to the infant. It is necessary to quantify how much language preterm infants receive to better understand how speech impacts the developing neonatal brain compared with those infants born at term gestation. This information can guide developmental support for these at-risk infants. It will also allow us to identify infants at increased risk for language deprivation due

to lack of visitation. Using 16-hour audio recordings during NICU hospitalization, we will compare the amount of speech or adult word count (AWC) preterm infants receive when visitors are present or absent. During periods of higher AWC we will analyze speech type (infant-directed or parent-directed), who is speaking (parent or health caregiver), and whether the speech is in response to the infant (child's cries, alarms, etc.). It is expected that infants with parental visitation will be exposed to a greater amount of speech, but it is unknown whether health caregivers adjust their speech based on family presence. Parental speech and interaction have been linked with early bonding and better cognitive outcomes. By understanding the best auditory environment for preterm infants, we can better guide parents and medical staff about family involvement, auditory stimulation, and speech exposure for NICU infants.

Abstract Name: Exploring Sex and Age Related Amyloid Beta Accumulation in Sleep-Regulated Areas in an Alzheimer's Disease APPxPS1 Knock-In Mouse Model

Alzheimer's disease (AD) is a neurodegenerative disease that affects more than 7 million Americans. However, Alzheimer's disease impacts more than twice as many women than men. This disease is pathologically characterized by the formation of amyloid-beta plaques (A β) and neurofibrillary tangles in certain areas of the brain. Additionally, sleep disruptions and circadian rhythm fragmentation often precede AD onset and both are well-known AD risk factors. Disrupted sleep has been shown to increase A β production, decrease A β clearance, and increase cognitive decline. Interestingly, women experience more sleep problems throughout the lifespan, including a dramatic increase into middle-age and beyond. Correspondingly, women in middle-age and beyond accumulate A β pathology at a higher rate than age matched men. It is unknown why women experience increased rates of sleep disruptions and A β build-up with age. Using an AD mouse model, we aim to investigate the levels of A β in sleep-influencing regions of the brain in male and female mice throughout the lifespan. We hypothesize that females will have more A β pathology than males overall, that females will have more A β in sleep related areas than males, and that old females will have the most A β in sleep related areas of any subgroup. To test this, A β in males and females will be measured at two time points (~6mo and ~19mo) in sleep-influencing regions of the hypothalamus and brainstem by way of immunohistochemistry.

Abstract Name: How Do Compression Shorts Influence Lower Extremity Kinematics and Kinetics During a Countermovement Jump?

Femoroacetabular impingement (FAI) is a pathomechanical condition in which abnormal contact occurs between the femoral head and acetabulum, limiting hip motion, resulting in pain and restricting dynamic tasks such as jumping. Compression shorts engineered to facilitate hip external rotation may mitigate FAI-associated movement patterns by modifying lower-extremity alignment. This study examines the biomechanical effects of external-rotation compression shorts on lower extremity kinematics and kinetics during a countermovement jump (CMJ) performance. Twelve healthy adults completed five CMJs wearing standard athletic shorts and five CMJs wearing external-rotation compression shorts. Three-dimensional kinematics were captured using an 8-camera motion capture system sampling at 100 Hz, with 35 retro-reflective markers positioned on lower extremity landmarks. Concurrent ground reaction forces were collected with a 1000 Hz sampling rate. Sagittal and frontal plane hip, knee, and ankle angles were extracted to evaluate differences in peak joint motion between conditions. Experimental data were processed through an OpenSim pipeline to create participant-specific musculoskeletal models, perform inverse kinematics, run dynamic simulations, and conduct static optimizations to assess joint kinetics, muscle forces, and muscle activation patterns. The compression intervention is hypothesized to attenuate peak hip adduction and internal rotation, particularly during maximal depth and initial ground contact. Additionally, enhanced hip and knee joint stability is anticipated, decreasing medial knee collapse and modifying frontal-plane loading patterns. These changes may alter hip joint moments and shift muscle loading toward the gluteal and external rotator groups while reducing reliance on motion patterns associated with impingement. Overall, CMJ performance metrics, such as jump height and peak propulsive force, are expected to remain similar between conditions, indicating that movement strategies can be modified without compromising force production.

Abstract Name: Weathering the Next Crisis: The Future of NATO's Nuclear Umbrella in Uncertain Times

Russia's growing willingness to challenge long-standing nuclear norms, through escalatory rhetoric, the integration of Belarus into its nuclear posture, and lessons learned from its war in Ukraine, has raised concerns about the future credibility and stability of NATO's nuclear umbrella. As Moscow faces internal instability and the limits of its conventional forces, the risk of nuclear coercion or early nuclear use in a conflict may grow. In this context, the United States and NATO must evaluate whether new nuclear capabilities are necessary to strengthen extended deterrence and reassure allies. To do this, this research will specifically examine what nuclear changes the US and NATO could adopt to strengthen deterrence against Russia and the implications. It analyzes four potential U.S.-NATO nuclear options: nuclear sea-launched cruise missiles (SLCM-N), stand-off air-launched system (ALCM), ground-launched cruise missiles (GLCM), and expansion of the dual-capable aircraft (DCA) program. Each system is assessed using a decision matrix based on credibility, capability, communication to allies, communication to adversaries, financial cost, and effects on crisis and strategic stability. Because quantitative data on proposed systems is limited, the research relies on theoretical frameworks, historical analogies, and expert assessments of

deterrence, nuclear posture, and the strategic cultures of allies and Russia. Ultimately, this research aims to equip decision-makers with a framework to determine how their priorities compare and to identify the nuclear option that best fits their goals. By extending the current literature beyond capability-focused assessments, this research provides a more comprehensive analysis of the necessary factors to guide future nuclear policy.

Abstract Name: Psilocybin: Schedule One to Treatment One

Psilocybin, a bioactive compound found in certain types of mushrooms, has been used by a variety of cultures for thousands of years. Recent studies have highlighted the use of psilocybin as a potential treatment for psychiatric and neurological disorders such as anxiety and migraines, while ultimately limiting mortality rates connected to substance abuse and major depressive disorder. Psilocybin works as a serotonin receptor agonist, specifically targeting the 5-HT_{2A} receptor in the brain, which impacts physiological processes such as cognitive function and mood regulation. A key distinction of psilocybin is its ability to cause long-term changes without long-term treatment. While psilocybin has shown many benefits for mental health disorders, it does come with risks, such as tachycardia, emotional instability, and anxiety. Additional factors impeding clinical usage include the high cost of synthetic psilocybin production, current Schedule I classification, and ethical considerations of using a known hallucinogen with limited longitudinal research. This project examines the therapeutic effects, safety, and efficacy of psilocybin by analyzing a combination of peer-reviewed clinical studies and scientific articles dating back to 1959. Findings suggest that psilocybin demonstrates significant potential in treating anxiety, migraines, major depressive disorder, and substance abuse.

Abstract Name: Health and Homelessness: The Relationship Between Homelessness and Presence of a Health Condition

The purpose of this project was to evaluate the relationship between presence of a health problem and variables of homelessness. I assessed whether there is a statistically significant relationship between factors of homelessness, such as length of time homeless and being unsheltered, and the presence of a physical or mental health condition. Existing literature on the topic found statistically significant relationships between these factors, and also established that health conditions, and specifically chronic health conditions, can contribute to homelessness, as workers with chronic health conditions are paid less than their healthy coworkers, chronic health conditions are costly to manage, and presence of any medical debt is associated with an additional two years of homelessness. The aim of my study was to support the existing literature by evaluating ten years worth of Point-in-Time (PIT) Count data. The PIT is an annual federally mandated census of the homeless that involves the collection of mostly standardized information, such as age, gender, race, as well as information necessary to determine subpopulation categories like chronic homelessness or veteran status. The annual survey also includes questions about health and chronic health conditions. My data

was collected in 8 counties making up district 1 of Tennessee. I compiled this data into a large data set, creating a sample totaling 3,116 people. Preliminary statistical analysis indicates that there is a statistically significant relationship between presence of conditions such as physical disability, substance use disorders, and psychiatric conditions, and length of homelessness and chronic homelessness. These preliminary findings contribute to the growing academic consensus that the crisis of homelessness and the crisis of health are related.

Abstract Name: Exploring AI-Enhanced Learning with Vibe Coding: A Computer Science Micro-Internship Project

This presentation highlights a two-week micro-internship designed to immerse first- and second-year undergraduates at Roosevelt University in authentic research practices alongside a faculty researcher. For this project, students developed an AI-enabled system that generates personalized learning experiences for individual students, informed by both pedagogical research and direct student input. The project addresses a growing need in higher education to create adaptable, student-centered learning pathways that respond to diverse learner objectives. Five undergraduate participants were paired with a faculty mentor and guided through the research process from start to finish. Students completed human subjects training, learned and applied qualitative research methods by conducting peer interviews, transcribing the data, and preparing these transcripts as training inputs for an AI model. They further contributed by testing the system's ability to incorporate parameters such as learning goals and time limitations into a user-friendly web interface designed for instructors. Unique to this project, the team worked exclusively within the Vibe coding environment, gaining exposure to a streamlined development tool that supported their technical contributions while keeping the focus on research design and interpretation. Preliminary outcomes suggest that the student-built system successfully generates bespoke learning experiences, demonstrating the promise of combining learner insights with AI-driven pedagogy. Beyond technical accomplishments, the micro-internship fostered student confidence in conducting research, strengthened their collaborative skills, and provided a tangible example of how undergraduates can meaningfully contribute to faculty research. In this session, I will share insights into the mentorship process, the challenges and successes of the project, and the broader implications for cultivating research engagement early in students' academic careers.

Abstract Name: Double Spouted Nazca Based Vessel

This vessel is based on Nazca pottery featuring literal imagery in a cartoonish approach while utilizing earth toned underglaze for a painterly effect with wide and flat walls to properly display the image. The Nazca people took creative inspiration from the Paracas who utilized complex tiles as well as similarly styled and decorated ceramic pieces. They typically lived on the southern coasts of Peru in river valleys of the Rio

Grande de Nazca and Ica Valley though they did live a nomadic lifestyle giving us the Nazca or Inca lines while they travelled. Though the Nazca culture was prevalent from 100 BCE to 800 AD, their ceramic vessels became a large part of their culture from 200 BCE to 600 CE as they would use these as decoration, to depict certain imagery, as an offering or ceremonial piece, or to be used as a simple vessel. These artworks were made from rich and earthy clay found in riverbeds and wet plains. These pieces would be patently built with a coiling technique building up the sides and smoothing as you go. They applied mineral based colored slip to the outside of the vessel and placed it in a fire pit or open kilns that were heated to a temperature around 600-900° to preserve the color. This specific culture is significant because they have created an abundance of earthworks and artwork to show the cultural and spiritual importance of what they believe in and how they chose to express those beliefs, as well as the efforts put in to preserve and utilize the Earth given to them. Their additions to the pottery world have significance due to the use of multiple colors and the specific styles on the surface, really pushing the illustration and exaggerated features that make the designs pop.

Abstract Name: Centering Black Voices: Culture, Excellence, and Community Visions for the Center for Black Excellence and Culture in Madison, Wisconsin

Dane County home to the Wisconsin state capital, Madison, ranks among the worst in the nation for the prevalence of racial disparities for Black residents in carceral, educational, socioeconomic, physical and mental health outcomes. Black residents make up only 5.3% of the county population yet 56.4% of Dane County jails are made up of Black inmates (Austin & Oeker, 2023; Census, 2020). According to Kids Forward (2023), there is an income gap of \$42,248 between white and Black residents and an unemployment rate 2.8 times higher for Black residents compared to white residents. Additionally, disparity is prevalent in education as Black fourth graders in Dane County schools average in the 12.5 percentile for English Language Arts (ELA) and 6.4 percentile for math proficiency compared to their white peers averaging 58.7 percentile in ELA and 46.9 percentile for math. This study aims to address the persistent racial inequality within Dane County by centering the hopes and addressing the needs these disparities create for Black residents in the development of the upcoming Center for Black Culture and Excellence, opening in Winter 2026. ("The Center"). The Center hopes to be the heart of Black life in the predominantly white city of Madison, Wisconsin. Grounded in the theory of McKittricks (2016) Black geographies, this study examines the provisions and atmosphere Black Madison residents hope for The Center through in-depth interviews with 42 residents. This qualitative inquiry centers Black voices by illuminating the needs and desires of residents to ensure The Center adequately supports the Black Madison community. Using collaborative thematic analysis, this study found that residents hope for The Center to provide culturally responsive resources and serve as a safe and inclusive atmosphere that affirms all identities belonging within the Black Madison community.

Abstract Name: Engaging Communities outside the Classroom: Challenging Knowledge Formation and

Expected Processes in the Urban Studies Field

Students are expected to be able to follow the process of an assignment laid out by professors. Following this process successfully and creating the desired outcome earns the student a satisfactory grade. But projects in the real world, especially community-engaged urban projects, do not follow laid-out guidelines. This presentation seeks to answer the question: how does practical community engagement experience through immersive projects give students new perspectives that challenge traditional research processes and knowledge production? The presentation addresses this question through comparative case studies of personal experiences in a UW-Milwaukee undergraduate research project in the Midtown neighborhood and a Public Service Enterprise Group Institute for Sustainability Studies (PSEG-ISS) research project in Newark, New Jersey. The site field work, community engagement, interviews, and deliverables completed within these projects expand students' understanding of the complexities of community-engaged projects and their effect on how knowledge is and should be produced. In the Midtown neighborhood project, residents were engaged through the creation of visual designs and facilitation of public meetings. In the Newark project, stakeholders such as the city's sustainability office were contacted through the lens of a professional internship. In this study, it is found that through stakeholder interactions and collaborative design and planning processes, students gain a first-hand understanding of complicated urban problems. Studies outside of the classroom challenge students to collaborate with stakeholders and engage these issues, rather than simply read about them. The experience of producing research outcomes like maps and design plans allows students to see unimagined or hard to understand outcomes of urban projects as the community engages with the formation of public spaces.

Abstract Name: Combat Veterans and Comorbid Illness: Treatment of Traumatic Brain Injury (TBI) and Post Traumatic Stress Disorder (PTSD)-associated Symptoms through Transcranial Magnetic Stimulation

This review examined transcranial magnetic stimulation (TMS) and its use to combat the treatment complications that are caused by comorbid and triple comorbid PTSD, depression, and anxiety in United States combat veterans with and without Traumatic Brain Injuries (TBI). As comorbid depression and comorbid PTSD rates of United States veterans rise, veterans struggle to contribute to the nation both economically, and physically, due to mental and social impacts of comorbid PTSD and depression. An analysis of literature comparing TMS with PTSD and comorbid PTSD, showed that TMS is an effective treatment option for veterans with comorbid PTSD, when examining outcomes of patients with and without TMS treatment both over time, and for short term use. For patients with triple-comorbid PTSD, usage of first line treatments, such as SSRI medications, may not offer full remission or reduction from PTSD and depression symptoms, as the combination of anxiety with comorbid depression and/or PTSD becomes resistant or may decrease effectiveness of treatment. TMS treatment on US veterans is not affected for patients with TBI compared to without, but TBI does have an effect on the likelihood of comorbid illness development, which decreases the efficacy of TMS treatment, as well as first line treatment options. Overall, TMS can be used as a resource to treat comorbid depression and PTSD symptoms in combat veterans, in addition to combined therapy such as SSRI medication, cognitive processing therapy (CPT), and psychotherapy, but more research is needed for TMS treatment for patients with TBI and comorbid PTSD, depression, and anxiety, due to the longitudinal effects that accompany patients treatment courses.

Abstract Name: Metal Exposure, HbA1c, Protein Biomarkers and Cognitive Function in Older Adults: A Pilot Study in Laredo, Texas

Sources of metal contamination from both industrial and natural sources may be disproportionately affecting disadvantaged border communities in Laredo, Texas. Chronic metal exposure has been linked to accelerated cognitive decline in older adults. At the same time, poor glycemic control—assessed via hemoglobin A1c (HbA1c)—is highly prevalent in this area, which may pose a risk of neurotoxicity. Little is known regarding the impact of metal exposure, diabetes severity, and neurotrophic or neuroprotective protein biomarkers such as sirtuins (SIRTs), vascular endothelial growth factor (VEGF), and nerve growth factor (NGF) on cognitive aging and Alzheimer's disease and related dementias (AD/ADRD). A pilot study will examine these potential relationships among older adults over the age of 65, who are residing in Laredo. Blood samples will be collected from 60 participants to measure metals such as arsenic (As), lead (Pb), and cadmium (Cd), HbA1c, and protein biomarkers including SIRTs, VEGF, and NGF in blood samples. Cognitive function will be assessed using NeuroUX, a computerized tool evaluating memory, attention, processing speed, and executive function. Multivariable regression models will examine associations between metals, HbA1c, protein biomarkers profiles, and neurocognitive outcomes, adjusting for key demographic and health characteristics. An inverse association between historical metal exposure and cognitive function scores is expected. Additional analyses will determine whether higher HbA1c levels are independently associated with poorer cognitive performance and whether diabetes severity modifies associations among metal exposure, circulating biomarkers, and specific cognitive domains. Lower levels of neuroprotective biomarkers (SIRTs, VEGF, NGF) are also expected to correspond with lower cognitive performance. Findings from this pilot study will inform future research on early detection strategies and environmental and metabolic risk mitigation for AD/ADRD, particularly among older adults in Laredo and similar communities.

Abstract Name: The Worst of Both Worlds? The Practical Neuroscience of AuDHD

Autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) share several core symptoms, such as executive dysfunction and emotional dysregulation. However, though these symptoms may appear similar between disorders, they often arise from different cognitive and neurological mechanisms. When these mechanisms overlap, they result in more severe symptoms than those from either disorder alone, making their significant rate of comorbidity a salient concern. Therefore, proper treatment of comorbid ASD and ADHD requires understanding how each disorder contributes to its presentation. The objective of this project is to provide a synthesis of the current literature on co-occurring ASD and ADHD (often colloquially

referred to as ‘AuDHD’), and, using the conclusions drawn, form strategies for individuals to manage the day-to-day occurrence of symptoms.

Abstract Name: The Effects of Magnesium Supplementation on Muscle Degradation and Renal Function in Endurance Athletes

Magnesium is an essential mineral. It helps with muscle contraction, energy production, and cell recovery. High-endurance athletes have been shown to be prone to magnesium deficiency due to greater metabolic demands and loss through sweat. This may lead to muscle damage and poor recovery. This study will examine whether daily magnesium supplements affect muscle breakdown and kidney function in long-distance runners over six weeks. The expectation is that steady magnesium intake will lower serum biomarkers of muscle damage and keep kidney function normal. A pre–post intervention design will be used with trained endurance runners. Participants will take a standardized magnesium supplement daily for six weeks. Blood samples will be taken before and after supplementation. Serum will be kept at –80°C until analysis. Myoglobin, creatine kinase, and interleukin-6 will be measured with ELISAs to assess muscle breakdown. Kidney function will be tested using a renal function panel. Paired t-tests and an ANOVA will compare mean pre- and post-supplementation results for all analytes to find significant changes. It is expected that magnesium supplementation will result in decreased serum concentrations of muscle damage biomarkers without adversely affecting kidney function. The findings of this study aim to clarify magnesium’s influence on muscle integrity and renal regulation during prolonged endurance activity and may support the development of nutritional strategies to enhance athletic performance and recovery.

Abstract Name: Make Food with Love: Exploring the relationships between food production, tradition, and identity through documentary photography

Due to the industrialization of food systems, a lack of access to green space in urban areas, and a lack of knowledge of our native ecosystems, there is an increasingly significant disconnect between our meals and the people and places that produce them. "Make Food with Love" merges the cookbook with the artist book in a documentary photography recipe book that seeks to answer the following questions: How are culture and tradition held in food production and consumption, and how do different methods of food production provide a connection or disconnection from what we consume? With this project, I aim to make the viewer question their relationship with their food, the natural environment, and those who produce the food they consume. The work argues for a reconsideration of our relationship to the environment and a conscious way of consuming. This research sits at the intersection of art, ecology, and social justice. Gathering inspiration from books such as *Omnivore’s Dilemma* and *Braiding Sweetgrass* and photographers such as Lucas Foglia, Laura

McPhee, and Michael Schmidt, this work explores how these disciplines interact and can inform each other. For this project, I visit and work with people involved in diverse forms of alternative food production, from small-scale regenerative farming to backyard gardens to urban foraging. Photographing in my own kitchen and those of the ones I love, I make images that display the power of food to create community and carry tradition. From these experiences, I learn about sustainable practices, gather recipes, and collect photos of people, land, and food. The conclusion of this research is a collection of photographs as prints and in the final artist recipe book, which is to be reproduced and shared with those involved in the project.

Abstract Name: Nature as Healer: Documenting Cross-Cultural Applications of Nature-Informed Therapy in Ukraine and the United States

This documentary examines how nature-informed therapy (NIT) is being introduced, adapted, and implemented across cultural and geopolitical contexts by following a focused segment of the partnership between Ukrainian mental health practitioners and the U.S.-based Center for Nature Informed Therapy (CNIT). The film uses audiovisual recording as both a research method and a mode of dissemination. Primary filming took place in April 2025 during a training event in Hungary, where nearly 30 Ukrainian therapists and community leaders received instruction from a U.S. psychologist specializing in NIT. This initial fieldwork captured workshop content, participant reflections, and observational footage illustrating how trauma-affected communities engage with natural environments for emotional regulation and recovery. Throughout the summer, the documentary followed the U.S. facilitator's clinical work at CNIT, providing contextual grounding for how NIT's established applications. In fall 2025, two Ukrainian trainees attended CNIT's official training program in Maryland. Their follow-up interviews, recorded on-site, offer insight into the implementation of NIT practices in Ukraine amidst ongoing war, displacement, and community anxiety. The film places particular emphasis on the practical adaptations emerging in Ukraine, such as the use of botanical gardens and accessible green spaces to reduce stigma around formal therapy. These recorded accounts provide evidence of how nature-based modalities can expand treatment access in areas where conventional therapy faces structural or cultural barriers. This project also demonstrates how film can function as a tool for expanding public awareness of emerging mental health modalities. By circulating these narratives beyond academic and clinical settings, the film supports broader engagement among the very communities that stand to benefit most—particularly those underserved by traditional clinical systems. These are also the groups that will likely be engaged with in the feature-length expansion of this project, including Indigenous reservation-based health systems and incarceration re-entry support workers.

Abstract Name: Written onto the Land: The Legacy of Racial Covenants in Minnesota Housing

Racially restrictive covenants in housing deeds were a common legal tool in the early 1900s used to maintain racial exclusion and create all-white neighborhoods. In Minnesota we observe covenants starting in 1910 and

persisting even after they became unenforceable following the *Shelley v. Kraemer* (1948) Supreme Court ruling. Covenants operated alongside racial hierarchy norms, intimidation and violence, and later discriminatory lending and redlining beginning in the 1930s. Understanding the historical mechanisms of segregation can clarify the roots of present-day racial disparities in housing and neighborhood composition across Minneapolis and St. Paul. We hypothesized that the presence of racial covenants would statistically predict residential segregation metrics, such as the prevalence of all-white neighborhoods and racial residential evenness as measured by the dissimilarity index. Using data from the Mapping Prejudice Project (MPP) and Integrated Public Use Microdata Series (IPUMS) USA Full Count Census, we employ regression analysis to analyze how racially restrictive covenants shaped patterns of residential segregation in Minneapolis and St. Paul from 1910 to 1940. Regression results show that while covenants indicate a statistically significant relationship with segregation in 1940, they do not consistently predict the persistence of all-white neighborhoods or high dissimilarity across 1910-1940. These findings suggest that racial covenants may have reinforced rather than independently caused segregation, indicating that non-covenant mechanisms, such as violence, intimidation, and later discriminatory lending, played equally substantial roles.

Abstract Name: Unveiling the Marital Paradigm Beliefs of Emerging Adults

Throughout the past decades marital trends have changed drastically within the United States. While the legalization of same-sex marriage allowed for more people within the United States to get married, marriage rates continue to decline and young adults are marrying later in life. To better understand how emerging adults conceptualize marriage, a phenomenological study was conducted and included people of color, heterosexual and queer individuals from the Midwest. Semi-structured interviews were used to examine participants' thoughts, beliefs, and experiences related to marriage itself and their preferences regarding marriage. Results showed that several factors impact the way participants view marriage or value its importance, such as priorities for education and career advancement in regards to achieving financial security; how marriage was modeled to them, especially by parents, peers, and modern media; and individual identity, including race/ethnicity, religion, gender, and sexuality. Results from this study have both clinical and policy implications.

Abstract Name: Evaluation of reproductive hormones and gonadal tissues from feline offspring from AAV-GnRH treated cats

Overpopulation of stray cats presents a significant challenge to both animal welfare and public health. Although surgical sterilization remains the primary method of population control, it is resource-intensive,

requires trained veterinary personnel, and can impose physical and psychological stress on animals. A non-surgical alternative could reduce these barriers and support large-scale population management. This study evaluates adeno-associated virus-mediated delivery of gonadotropin-releasing hormone (AAV-GnRH) as a potential non-surgical sterilization strategy for domestic cats. AAV is a nonenveloped viral vector capable of targeted DNA delivery and long-term gene expression, making it a promising platform for reproductive hormone modulation. Although adult cats treated with AAV-GnRH remained fertile, their offspring exhibited altered luteinizing hormone (LH) concentrations during the first eight weeks of life. These findings prompted investigation into whether the viral vector or associated immune responses may be transferred vertically from treated parents to their kittens. The current project aims to assess the presence of AAV-GnRH in neonatal tissues and to characterize additional hormone profiles that may be influenced by treatment. Ongoing analyses include qPCR-based detection of AAV antibodies in tissues collected from treated adults and their offspring. Preliminary data from three kittens born to a treated mother showed no detectable differences in heart or liver tissues compared with untreated controls, though additional sampling is still underway. The gonads of treated cats were also tested alongside those of a negative control. A slight increase in AAV-associated antibodies was observed in treated adults; however, the difference was minimal and not statistically significant. This is important because there is no significant immune response suggesting the AAV treatment was tolerated and likely sustainable long term. Continuing work will clarify the potential for vector transfer to offspring, characterize hormonal changes in neonatal kittens, and provide essential safety and efficacy data for the development of AAV-based, non-surgical sterilization methods.

Abstract Name: High competitiveness enhances both speed and accuracy of working memory on a value-directed remembering task

Competitiveness is defined as an individual's drive to outperform others and to achieve high success. While prior research has explored the effects of competitiveness on various cognitive domains, limited work has examined its influence on laboratory-based memory processes. We predicted that high competitiveness would help support working memory (WM) and mental control processes. This study tested whether people's self-reported competitiveness played a role in how well participants performed on a value-based working memory (WM) task and on a later unexpected long-term memory (LTM) test. Participants studied sets of words that appeared on the left and right sides of a computer screen. Later, these words were assigned either positive or negative point values based on the side they appeared on. After a short delay, a single word appeared, and participants indicated whether it had been a positive-value word from that same trial. Incorrectly endorsing a negative-value word resulted in point loss. Occasionally, a word from the previous round was shown to induce proactive interference, meaning that older information interfered with one's ability to focus on current information. Participants completed 60 of these WM trials, followed by a surprise LTM test and a 9-item questionnaire measuring competitiveness. Results showed that participants were less confused by negative-value words from previous trials, suggesting they successfully removed unimportant information from their memory. Analyses also showed that people who scored higher in competitiveness responded more quickly to high-value words and were more accurate overall in the WM task. However, competitiveness did not influence LTM, likely because participants were not expecting a later test. Overall, findings suggest that competitiveness enhances WM by improving both speed and accuracy of memory recognition through more efficient cognitive processes.

Abstract Name: Algal blooms in urban Minnesota lakes: Does effectiveness of aluminum sulfate (alum) change over time?

Water pollution, an excess of nutrients (eutrophication) like nitrogen (N) and phosphorus (P), can cause algal blooms, some of which are harmful. To manage blooms, the chemical aluminum sulfate (alum) is added to lakes, binding bioavailable P and settling it to the sediment. However, alum effectiveness depends on water pH, sediment resuspension, and organic matter. Its effectiveness may change with time, leading to nutrient shifts as less phosphorus stays bound, especially if nutrient inputs continue. The ratio of total N to total P (TN:TP) influences which algal species are present and their competitive interactions and thus, can determine the presence of algal blooms. This study examined the relationship between time since alum treatment and algal assemblages in three urban Minnesota lakes: Lake Holiday (1 year), Bur Oaks (3 years), and North Lake (5 years). As low TN:TP is associated with increased toxic cyanobacterial blooms, and alum treatment reduces P, water bodies with more recent alum treatment should have lower numbers of cyanobacteria. Integrated phytoplankton samples were pulled from surface waters 1-1.5 meters in depth during 2024 and 2025 summers. Samples were analysed with a FlowCam 5000® (fluid imaging particle analyzer) and sorted into major groups (cyanobacteria, diatoms, green algae, dinoflagellates, cryptophytes, and euglenoids) and toxin-producing ability. Holiday remained dominated by cyanobacteria, but *Microcystis* (a toxin-producing cyanobacteria) and cyanobacterial filaments increased, while green desmids and cryptophytes decreased, suggesting a shift in nutrient ratios. Bur Oaks shifted from cryptophyte to diatom dominated. North Lake remained dominated by cyanobacteria, but toxic, N₂-fixing genera increased. The increase in cyanobacteria over time suggests the need for follow-up alum treatments to control harmful algal blooms. High cyanobacteria levels in Lake Holiday indicate that alum and algal assemblage dynamics require more research. The effectiveness of alum may be sensitive to initial nutrient conditions.

Abstract Name: Exploring the Variation in *tsiv2* Gene Copy and Sequence in *Vibrio fischeri*: Implications for Self vs. Non-Self Recognition

Bacteria interact with each other in many different forms through both direct and indirect means. The type VI secretion system (T6SS) is a means of direct competition where one bacterial cell physically injects another and releases toxic effectors. With these toxic effectors, there must be a way to neutralize them, and that task is completed by immunity factors. Currently, literature is lacking in characterization of these effectors and immunity proteins. To address this gap, we utilize the symbiosis between *Vibrio fischeri* and the Hawaiian Bobtail squid, *Euprymna scolopes*. This symbiosis provides an ideal platform to study interactions within only the *V. fischeri* species. *VasX* is one of the toxic effectors that has been found in the *V. fischeri* genome. Its counterpart immunity factor, *TsiV2* has been found directly downstream of *VasX* in the genome. The number and sequence identity of the *tsiv2* genes differ between and even within each strain. It has been hypothesized that the varying *TsiV2* proteins are utilized in competition to neutralize both self and non-self *Vas X*, but the function of each different *tsiV2* gene is poorly understood. To address this hypothesis, we have

analyzed tsiv2 genes using sequence alignments and gene synteny, as well as begun phenotypic characterization of the tsiv2 variants during bacterial competition. These findings will increase our understanding of the function for tsiv2 genes in competition between bacterial symbionts possessing the T6SS. With a better understanding of their mechanisms, more effective treatments for bacterial infections can be created, and the bacterial nanotechnologies could be mimicked for medical use.

Abstract Name: Institutions in the Mind: Comparing Index-Based and Perceived Economic Freedom as Predictors of Entrepreneurship and GDP

Our project aims to examine how individuals and businesses perceive economic freedom and how those perceptions differ from traditional measures based on institutional characteristics. Existing indices, such as the Fraser Institute's Economic Freedom of North America (EFNA), rely entirely on quantifying policy variables, where data about government spending, taxation, labor regulation, legal quality, monetary stability, and trade openness are used to assess economic freedom. However, these indices overlook how these policies are experienced by entrepreneurs, consumers, and workers. Perceptions can substantially influence behavior, decision-making, and economic outcomes. In this project, we therefore aim to capture entrepreneurs' and managers' perceptions of economic freedom, to develop an index of perceived economic freedom, and to compare our index with the EFNA as predictors of entrepreneurship and GDP. For this purpose, we will design a survey containing items closely aligned with the EFNA's core areas, with a particular focus on government spending, taxation, and labor market freedom. Our survey will be rolled out using Prolific, a web service to connect researchers with participants nationwide. Participants will be American entrepreneurs and managers. We hypothesize that perceptions of economic freedom will significantly differ from the EFNA and that they will better explain variations in entrepreneurship and GDP in the United States than the EFNA alone. Our goal is to combine this new perceived index with existing EFNA data to inform policymakers more effectively.

Abstract Name: Do Artificial Intelligence Detectors Work? The Effects of Generator and Prompt Type on Detection Accuracy and Reliability in Academic Settings

The recent rise in the prevalence of artificial intelligence (AI) in academic settings has contributed to increased doubt regarding the accuracy of AI detectors. These concerns emerge because student writing falsely classified as AI generated can lead to negative consequences including plagiarism allegations and student sanctions. Previous studies have demonstrated that AI model and detector impact predicted AI-generated text (AIGT) percentage. However, given the extensive variety of AI generators and detectors utilized in academic settings, additional investigation into the performance of less-researched yet common tools is necessary. Correspondingly, an experiment was conducted to investigate the following research question: How do generator and prompt type affect the accuracy and reliability of common AI detectors? Alongside student-written responses, ChatGPT-5, Claude, Copilot, and DeepSeek were used to examine detection across common AI generators. To allow for investigation in realistic academic settings, three prompt types common to this environment were included: a short-answer quiz response, a project-report methods section, and a methods section for an academic manuscript. Extraneous factors such as topic and word length were standardized across conditions. Detection accuracy was assessed for two common detectors: Grammarly and Scribbr. With multiple outcomes of interest, a multivariate analysis of variance (MANOVA) was conducted, and group comparisons were used to identify possible effects on AIGT detection. Results indicate that the generator and prompt may both play a role in the detection results of at least one detector. The text generator had a prominent impact on the percentage of text flagged as AIGT. Additionally, a significant effect for prompt was detected under certain conditions. While detectors generally distinguish between student and AI responses, a concerning number of false positives, inconsistency between and within detectors, and the potential risk of academic penalties tied to incorrect detection imply that AI detectors cannot yet be reliably implemented in academia.

Abstract Name: Scorpion Venom Based Antiviral Peptides Targeting 3-Chemotrypsin Like Protease of SARS-CoV-2

A new type of coronavirus was first detected in December 2019 at Wuhan city, the capital of the Hubei province of China. This virus is designated as severe acute respiratory syndrome-related coronavirus-2 (SARS-CoV-2). Like other coronaviruses, SARS-CoV-2 has 4 structural, 16 non-structural and 9 accessory proteins. The 3-Chemotrypsin Like Protease (3CLpro) encoded by ORF1 as nsp5 has been found to play a

critical role in viral polyproteins maturation and replication. It is a protease similar to chymotrypsin that utilizes cysteine rather than serine as a nucleophile in the active region of the protease. The viral replication process could be interrupted or stopped if the activity of this enzyme is inhibited. Peptide therapeutics are effective because of their high affinity with receptors and low toxicity. Additionally, they can reduce off-target side effects because of their target specificity. Scorpion venom contains a mixture of peptides and proteins with varied bioactivities and receives great attention due to their potential application in peptide drug development. The aim of this research is to synthesize scorpion venom peptide using chemical synthesis and test their effectiveness on inhibiting the 3CLpro. The scorpion peptides were synthesized using solid phase peptide synthesis protocol with a high swelling rink-amide resin with a loading capacity of 0.6 mmol/g and mesh size of 100-200. After the peptide synthesis, the peptide-resin complexes were cleaved with 95% TFA, 2.5% H₂O, and 2.5% Triisopropylsilane. The cleaved peptides were filtered and precipitated by adding cold ether. The purity and identification of the peptides were confirmed by liquid chromatography and mass spectrometry. The inhibition efficiency of peptides against 3CLpro was tested using FRET assay, the best candidate peptide showed an IC₅₀ value of 6.65 micromolar, indicating that 3CLpro activity was significantly reduced with increased peptide concentration.

Abstract Name: Mutations in the ERBB4-ERBB2 Dimer Interface May Elucidate the Role of These Dimers in BRAF-WT Melanomas

Introduction: Melanoma is an aggressive and deadly subtype of skin cancer. Approximately half of melanomas harbor a gain-of-function mutation in a BRAF allele. The growth of these tumors is reduced by immune checkpoint inhibitors (ICIs) or a combination of BRAF and MEK inhibitors. Unfortunately, the melanomas that possess a wild-type BRAF allele (BRAF-WT melanomas) are not responsive to targeted therapeutics, and ICIs are not highly effective against these tumors. Thus, our long-term goal is the development of drugs that are effective against BRAF-WT melanomas. Methods and Anticipated Results: We have previously shown that expression of the ERBB4 receptor tyrosine kinase gene is both sufficient and necessary to drive the proliferation of four BRAF-WT melanoma cell lines. ERBB4 encodes a receptor tyrosine kinase that is closely related to the Epidermal Growth Factor Receptor (EGFR), ERBB2 (HER2), or ERBB3 (HER3). Moreover, three ERBB4-dependent, BRAF WT melanoma cell lines also depend on ERBB2. Previous data indicate that ERBB4 homodimers inhibit tumor cell proliferation. Thus, we hypothesize that ERBB4-ERBB2 heterodimers drive these ERBB4- and ERBB2-dependent, BRAF-WT melanoma cell lines. To test this hypothesis, we are evaluating the activity of mutant alleles that affect the cytoplasmic ERBB2/ERBB4 asymmetric dimer interface. We are testing whether mutations in the N-lobe of the ERBB4 kinase domain cause loss-of-function phenotypes (reduced signaling and stimulation of proliferation) and whether mutations in the C-lobe of the ERBB2 kinase domain cause loss-of-function phenotypes. Finally, we will test whether the activity of loss-of-function ERBB4 N-lobe mutant alleles can be rescued by loss-of-function ERBB2 C-lobe mutant alleles. Anticipated Conclusion: Positive results would suggest that ERBB4-ERBB2 heterodimers drive the proliferation of ERBB4- and ERBB2-dependent melanomas and that such melanomas will respond to combination therapies that feature FDA-approved anti-ERBB2 agents, including pertuzumab and lapatinib.

Abstract Name: From Treatment, Recovery to Relapse? Investigating The Role of Ultra-Processed Food (UPF) in Colorectal Cancer Survivorship

Background: Ultra-processed foods (UPF) are industrial formulations made from food-derived or synthetic substances that contain little or no whole foods and are typically ready-to-consume, high in fat, salt, or sugar, low in fiber and nutrients, including items such as packaged snacks, sugary beverages, confectionery, and processed meats. UPF has been associated with increased colorectal cancer risk. However, the effect of UPF intake on colorectal cancer survivorship remains underexplored. Objective: This study aimed to summarize the evidence on associations between UPF intake and colorectal cancer survivorship outcomes while exploring underlying biological mechanisms. Methods: A systematic literature search identified 3,450 peer-reviewed publications, 57 of which were included in this review. Survivorship outcomes were categorized into mortality (n=17), treatment-related toxicities (n=25), or quality of life (n=15). Results: Higher UPF intake was consistently associated with increased colorectal cancer-specific mortality. Evidence also indicated associations between higher UPF intake and poorer quality of life, including sleep disturbances, elevated fatigue, and reduced physical and psychosocial functioning. Additionally, several studies reported increased treatment-related toxicities linked to UPF intake, such as gastrointestinal symptoms, adverse side effects, and treatment discontinuation. Proposed biological mechanisms underlying these associations included systemic inflammation, gut microbiota disruption, and metabolic dysregulation. Conclusion: Our review suggests that higher UPF intake is associated with increased colorectal cancer-specific mortality, poorer quality of life, and greater treatment-related toxicities. Considerable heterogeneity was observed across studies in how UPF intake was assessed. Future research should prioritize prospective, longitudinal designs and integrate objective biomarkers, such as metabolomic profiles, to improve measurement of post-diagnosis dietary exposures and their impact on survivorship.

Abstract Name: Presence of Residual Explosives on Varying Surfaces as Detected by an Explosive Trace Detector

Canine Explosive Training Aids (CETAs) are a valuable training tool used by the Canine Training Center (CTC) to train explosive detection canines. CETAs contain true explosive material and must be handled with caution to ensure safety and prevent contamination. Even with proper packaging and procedures, there is still a concern for contamination of the CETA and the training environment. This study investigated whether residual explosive particles were present and how long they remained after the CETAs were removed from a training area. It also evaluated whether the surface the CETA was on affected how long the residual particles remained. A series of locations were set up with CETAs and then swabbed at 0 hours, 1 hour, 4 hours, and 24 hours after the CETA was removed. An explosive trace detector (ETD) analyzed the swabs for the presence of explosive particles. Results indicated that CETAs can leave residual particles, but this varies depending on the explosive within the CETA. Additionally, the surface the CETA was placed on affected how long the residual particles remained. Due to sensitive information requirements, the identities of the explosives were withheld and instead referred to as Substance X, Substance Y, and Substance Z. The CETA containing Substance Y had particles that remained for at least 24 hours on a carpeted surface and less than one hour on a hard surface. Further testing is needed to identify the trends of other explosives not covered in this study and to determine how long residual particles can remain beyond 24 hours.

Abstract Name: Effects of Ketogenic Diets on Neuroblastoma Tumor Growth in Adjuvant Therapy Versus Monotherapy via Xenograft Mouse Model

Neuroblastoma is a pediatric cancer with poor prognosis in high-risk cases, with survival rates remaining below 50% despite current available treatment. The need to develop and implement new neuroblastoma treatment methods are critical, as neuroblastoma accounts for 15% of childhood cancer-related mortality. Because high-risk neuroblastoma shows strong dependence on glycolysis for energy, known as the Warburg effect, safe nutritional interventions that shift tumor metabolism offer a critical path for therapeutic improvement. The ketogenic diet reduces glucose availability and elevates ketone bodies, creating metabolic pressure on glycolysis-dependent tumors and giving this approach increasing potential as an alternative therapeutic strategy. This study investigates the relative impact of monotherapy with ketogenic diets and adjuvant therapy integrating ketogenic diets with chemotherapy on neuroblastoma xenograft tumor growth and viability. Using a two-way ANOVA, data on tumor volume (mm^3) and percent survival (%) were extracted and compared from two studies, one exhibiting a monotherapeutic approach and the other a KD adjuvant approach. Through analyzing two cell lines (SH-SY5Y and SK-N-BE(2)) over a 22-day period, results showed no statistical effectiveness of the type of treatment or cell line on overall tumor volume. However, the interaction between treatment and cell line approached significance, suggesting that an adjuvant approach in a chemoresistant cell line (SK-N-BE(2)) may impact tumor reduction. Overall, this study highlights a potential strategy for reducing toxic chemotherapeutic practices in high-risk pediatric oncology while simultaneously exploring alternate treatments that progress toward reducing neuroblastoma mortality rates.

Abstract Name: Positional Effects of Electron-Deficient Heterocycles on the Emission and Aggregation Behavior of polycyclic-1,2-BN-heteroarenes

Incorporation of a boron–nitrogen (B–N) unit into polycyclic aromatic hydrocarbons generates azaborines, a versatile class of heteroarenes that combine strong absorption, high photochemical stability, and tunable emission. Among them, nitro-substituted polycyclic-1,2-BN-heteroarenes (PBNHs) have emerged as promising electron-deficient n-type frameworks for organic optoelectronic devices. However, the introduction of $-\text{NO}_2$ groups often promotes strong π – π stacking, which induces aggregation-caused quenching (ACQ) and severely compromises fluorescence efficiency. To overcome this limitation, we designed and synthesized a series of PBNHs incorporating electron-deficient heterocycles at distinct positions on the pyrrolidinone hemisphere. By systematically varying heterocycle placement and introducing sterically demanding

substituents, we sought to distort molecular planarity, suppress intermolecular stacking, and induce aggregation-induced emission enhancement (AIEE). Comprehensive spectroscopic studies revealed that the positional orientation of electron-deficient heterocycles exerts a pronounced influence on photophysical behavior, modulating emission efficiency, spectral response, and aggregation tendencies. Several derivatives exhibited reduced ACQ, and in select cases, clear AIEE activity while preserving favorable absorption and stability. These findings demonstrate that positional control of electron-deficient heterocycles is a powerful strategy for tailoring the optical properties of BN-based chromophores. This design principle enables the development of next-generation electron-deficient AIE-active azaborine materials with significant potential in sensing, adaptive photonics, and optoelectronic applications.

Abstract Name: Going to WAR: Balancing Talent Accumulation with Situational Leverage to Refine Wins Above Replacement

Wins Above Replacement (WAR) reigns as the definitive metric in Major League Baseball because it standardizes disparate contributions, hitting, fielding, and positional value, into a single number. It allows analysts to instantly compare a defensive shortstop to a power-hitting first baseman. However, while WAR meticulously accounts for where a player plays on the field, it ignores when they perform. By design, WAR is context-neutral; it values a run scored in a blowout the same as a run scored in a high-leverage, game-deciding moment. This research questions whether prioritizing talent accumulation over narrative context has detached player valuation from the actual goal of the sport. Guided by the question, "What combination of methods produces the most accurate gauge of success?" this study utilizes a quantitative analysis of MLB team and player data from 2015 through 2025. I am employing multivariable regression and optimization modeling to compare the predictive power of WAR against situation-dependent metrics, specifically Win Probability Added (WPA) and Run Expectancy (RE24). The project tests the hypothesis that current models undervalue clutch performance. Preliminary analysis suggests that while WAR measures skill, it often misaligns with actual team outcomes because it dismisses the "luck" and timing that decide tight games. My continuing research aims to develop a composite statistic that weighs high-leverage performance more heavily than raw accumulation. Ultimately, this project seeks to bring the definition of value back to the only statistic that truly matters: team wins, arguing that a player's worth is defined not just by their talent, but by their ability to deliver when the game hangs in the balance.

Abstract Name: Applied Arts Lab at Virginia Commonwealth University

The mission of the Applied Arts Lab (AAL) at Virginia Commonwealth University School of the Arts is to reduce human suffering through visual design and storytelling. This project was founded by Jason Bennett

(Co-director, Department Chair of Communication Arts) & Sterling Hundley (Co-director, Communication Arts Professor). Students in the School of the Arts enroll through a Vertically Integrated Projects (VIP) course and work alongside medical professionals, scientists, and government officials to solve real world problems with real world impact. Current projects include Social Stories (a collaboration with the Evan-Haynes Burn Center to create illustrations for use with neurodivergent children), 3D prosthetic development, medical illustration, 3D scanning/modeling the Greenbank Telescope (the world's largest fully steerable radio telescope), and more. Students have successfully merged artistic skills with scientific research to produce tangible results. Through collaboration with CoStar Group, VCU students and professors have developed a detailed scale model of the 485 foot tall Greenbank Telescope using photogrammetry software and drone footage. The Stravitz-Sanyal Institute for Liver Disease and Metabolic Health worked with students to create four illustrations to explain liver conditions to patients in an accurate yet approachable way. Students have created a workflow for modeling prosthetics to fit patients in a rapid and economically efficient manner. By bridging the gap between design and scientific innovation, students at VCU School of the Arts are paving the way for future arts research. The Applied Arts Lab is creating impacts that can be seen and felt in the Richmond community and beyond.

Abstract Name: John Donne's Feminine Consideration of the Body of Christ in Death's Duell

As John Donne's preaching career came to a close, he delivered a potent sermon, posthumously titled "Death's Duell." A man widely considered to be consumed with death, Donne did not stray from remembering his own mortality and calling others to do the same. Donne's last sermon contains striking images of the human body, particularly the suffering body of Jesus. Using medieval theories on blood, the research of Caroline Walker Bynum, and a feminist lens, this paper explores how Donne presents an evidently feminine Jesus, especially in death. Even further, Donne calls his audience to respond to Jesus as one would to a mother, an occurrence seldom found in his other sermons or even his contemporaries' recorded sermons. This paper begins by investigating how Donne presents the woman's womb, that is, as a place of death which nourishes a child with blood, turning a life-giving body into one of death. Building on this idea, and in contrast to it, this paper then explores three aspects of Jesus' body mentioned in "Death's Duell": his circumcision, his crucifixion, and the human response to the dying body of Christ. Late medieval Christian's stressed the ability of blood to purge and nourish the body, often championing the women's body, which bleeds monthly. Similar to medieval depictions of Christ, Donne presents the dying Christ, his body and blood, as a source of food and nourishment, like a woman's body is to a child. The femininity of blood and the body was both subverted and championed in John Donne's "Death's Duell."

Abstract Name: The Underpromoter's Riddle: A Computational Analysis of the Knight Promotion in Chess

This research addresses a classic question in chess strategy: why do players sometimes underpromote to a knight (worth 3 points) instead of a queen (worth 9 points)? The goal is to move beyond decades of anecdotal

discussion to quantitatively determine if knight underpromotion is primarily a tool of tactical necessity or a matter of stylistic choice, and whether players miss hidden opportunities by defaulting to queen promotion. While chess databases track the frequency of underpromotion, they offer little insight into the rationale for the choice. Prior work has focused on general player performance, but no large-scale quantitative analysis has leveraged modern chess engines to classify the comparative outcomes of knight versus queen promotion decisions. This study fills this gap by analyzing the consequences of the decisions. We will consider a large database of high-level online chess games, examining promotion decisions from two complementary angles: when players chose knight promotion and when they chose queen promotion. The first angle addresses whether knight underpromotion represents tactical necessity or stylistic choice. The second angle examines whether players miss superior knight promotions by defaulting to queen. Utilizing the Stockfish chess engine in custom Python scripts, we will compare the outcome of the actual promotion choice to the outcome of the hypothetical alternative (knight if queen was chosen, or queen if knight was chosen) and classify the results through a 5-tier system: Brilliant, Optimal, Equivalent, Suboptimal, and Blunder. The findings will reveal whether knight underpromotion serves as a tactical tool versus a stylistic preference, and whether cognitive bias toward the conventional choice causes players to miss game-winning opportunities. This analytical framework will replace subjective opinion with objective data, providing an evidence-based answer to a classic question in chess strategy and serving as a model for analyzing human decision-making in complex environments.

Abstract Name: Modeling U.S. Home Prices Using Macroeconomic Variables

This project analyzes the macroeconomic determinants of U.S. housing prices by examining how key national indicators influence changes in the federal home price index over time. Using annual data from the Federal Reserve Economic Data (FRED) database, the study focuses on five major explanatory variables, GDP, the Consumer Price Index (CPI), the unemployment rate, the federal funds rate (FFR), and nationwide mortgage rates, to evaluate their combined impact on home price fluctuations. These variables were selected because they capture both broad macroeconomic conditions and factors that directly affect household purchasing power and housing demand. After collecting, cleaning, and transforming the data, multiple linear regressions were estimated to identify the significance and directional influence of each macroeconomic indicator. Diagnostic tests and graphical analysis were used to assess trends, potential outliers, and the economic plausibility of the results. The modeling framework allowed for a comparison of the relative contributions of each factor and highlighted patterns in the housing market across periods of volatility, including recessions and monetary tightening cycles. The empirical results indicate that the unemployment rate has a statistically significant and negative effect on home prices, consistent with the notion that weaker labor markets reduce household demand. CPI exhibits a positive relationship with housing prices, suggesting that inflation raises construction costs and nominal asset values. GDP also shows a positive association with home prices, reflecting broader economic growth. In contrast, both the federal funds rate and mortgage rates display negative coefficients, indicating that tighter monetary policy and higher borrowing costs tend to reduce housing demand and slow price growth. Overall, this project demonstrates that macroeconomic stability plays a central role in shaping U.S. housing price dynamics. The findings offer policymakers, lenders, and prospective homeowners insight into how shifts in the broader economy translate into changes in real estate values.

Abstract Name: Gender Differences in Phone Use Perceptions and Impact on Digital Availability in College Age Students

Digital availability is defined as the extent to which a user feels obligated to stay active in responding to digital communication messages. Research shows that one-third to one-half of college students use their phone in every class with negative effects including loss of focus, less understanding of course material and distraction from other students' phone usage. There is limited research examining if students are aware of how much time they spend on their phones. One study found that "light users" overestimated their phone usage due to anxiety of too much screen time, and "heavy users" underestimated their phone usage due to feelings of guilt. Females were more likely to underestimate the number of calls per week compared to males. Data collection for this study will occur at the start of the spring semester in January 2026. Students at a small, private university in the northeast United States will be recruited to complete an online survey using Alchemer and enter in a gift card raffle. Students will complete the Mobile Maintenance Expectations Scale (Hall & Baym, 2011) which assesses how much they feel others expect them to be available for messaging throughout the day. Students will also report how many hours they believe they spend on their phone during a typical weekday and weekend as well as the hours of actual cell phone use over the past week based on their phone data. We hypothesize that: (a) students' perceptions of their phone use will be significantly lower than their actual phone use time, (b) heavy phone users will report higher digital availability scores compared to light phone users, and (c) gender differences will be exploratory due to the limited available research. Students' knowledge of their personal screen usage can create an intervention and reduce hours spent on mobile phones.

Abstract Name: Fungal Degradation of Pretreated Plastic Waste

Plastic waste can persist in the environment for centuries, with natural degradation time ranging from 20 to 1000 years. Alongside damaging the environment, recent studies have concluded that microplastics have been found in the body, including the brain. This alarming presence shows that plastics can cross into the blood barrier and affect human health, emphasizing the importance of eliminating waste. One promising method is to biologically degrade plastics via fungal digestion. When plastics are fed to fungi as their sole carbon source, the fungi are able to break down the carbon present in the plastic. This research focuses on low-density polyethylene (LDPE) films. In an attempt to accelerate the rate of biodegradation, pretreatments are applied to plastics. These pretreatments include using nitric acid, sulfuric acid, hydrogen peroxide, heat, and microwave. Research will be done to see if modifying the surfaces of plastics through these treatments will aid in introducing more degradable functional groups on the plastic surface. Surface and chemical changes will be analyzed using infrared (IR) spectroscopy and scanning electron microscopy (SEM) imaging. The goal of this project is to determine if the pretreatment already established will work on everyday consumer

plastics for the future, therefore having the capability of both widespread application as well as effective elimination of excess plastic waste.

Abstract Name: Using Markov Chains and Statistical Analysis to Model Intentional Fouling Situations in NCAA Division 1 Men's Basketball

Intentionally fouling a team during their offensive possession is a strategy that basketball teams have employed for many years. Though popularized in the National Basketball Association (NBA), the technique has also made its way into Collegiate Basketball. The purpose of intentionally fouling is often to slow down opponent scoring and expose poor free-throw (FT) shooters. Despite previous studies using Markov chains or analyzing intentional fouling in the NBA, there is a lack of research combining these methods with collegiate men's basketball rules, particularly the one-and-one bonus. This paper will examine the optimal times to start intentionally fouling when trailing, using Markov chains and additional statistical analysis of data from NCAA D1 Men's Basketball. Additionally, this study will account for the Bonus and Double-Bonus rules specific to College Basketball. Play-by-play data was compiled from over 4,000 games in the 2024-25 season to calculate statistics that would help identify the probabilities of different plays. Transition matrices were created to determine the expected points in a possession with and without fouls. By categorizing data based on the time remaining in the game, the expected points for all D1 teams in various situations were calculated, enabling the development of a strategy to identify the optimal time for a team to benefit from fouling. The specific examples of the Florida Gators, Alabama Crimson Tide, and App State Mountaineers demonstrate that the optimal time to start fouling changes based on the opposing team. Additionally, the matrices were used to calculate the maximum FT% of a player for which it would be optimal to foul, rather than to give up a possession. While situations change on a game-by-game basis, the graphs created in this study will provide a general idea of when teams are expected to score fewer points in FT situations compared to offensive possessions.

Abstract Name: Shared Transcriptomic Signatures Between Traumatic Brain Injury and Hippocampal Aging in Sprague-Dawley Rats

Traumatic brain injury (TBI) survivors frequently suffer from chronically progressive complications, including accelerated brain aging, leading to cognitive decline. Current understanding suggests that TBI triggers inflammatory, immune, and metabolic effects that mirror mechanisms of aging. Yet, the molecular connection between TBI pathology and aging processes remains unclear. To address this gap, we acquired and analyzed hippocampal RNA-seq data from public rodent TBI and aging studies. Rna-seq was processed

with nf-core/rnaseq pipeline, and analyzed using differential gene expression analysis, GO enrichment analysis, and WGCNA to identify shared biological signatures between TBI and aged animals. We found 594 TBI-associated and 74 aging-associated differentially expressed genes (DEGs), with 29 shared upregulated genes between the conditions. These overlapping DEGs converged on immune related pathways, particularly antigen presentations, adaptive activations, and complement associated synapse remodeling. Network level comparisons showed that the patterns of gene co-activation after TBI resembled those found in aging, particularly in immune and neuroinflammatory pathways. Patterns of gene enrichment also indicated strong representation of peripheral immune-associated transcripts, evidencing that TBI engages systemic immune mechanisms resembling those seen in immune aging. Taken together, these findings show that TBI and aging share coordinated transcriptional patterns centered on adaptive immunity, neuroinflammation, and synaptic regulation. This alignment supports the emerging view that TBI can induce an age-advanced transcriptional state in the hippocampus. Additionally, the prominence of peripheral immune signatures raises the possibility that TBI functions not only as a localized brain injury, but also a body-wide immune event that mirrors or accelerates key molecular features of biological aging.

Abstract Name: Voicing Sapphism on Campus: An Oral History Project

Sapphic or women-loving-women (WLW) identity is considered an inclusive and embrative LGBTQ+ identity that refers to women and non-binary people attracted to other women. While this identity label is broad, it is often debated and controlled to limit people's inclusivity into the group. This study documents the sapphic identity within the contemporary college environment. Focusing on the intersections between sexuality and gender, their relationship to safety and openness is explored. The college setting is characterized by the intersecting and overlapping of identities, including different age ranges and roles in academia. The methodology for this project involves conducting oral histories with five faculty members and ten undergraduate students at the University of Kentucky (UK) to document the materiality, society, and community of the sapphic identity. The interviews will be recorded and deposited in the Louie B. Nunn Center for Oral History at the UK Libraries Special Collections Research Center for future research. Themes about safety as a campus community member, associations and connections to labels and materiality within queer spaces will be recorded. The aim of this study is to document sapphic voices within the University of Kentucky college campus. As a large, public R1 campus, UK attracts a diverse body of students, yet sapphic identity remains outside of predominately heteronormative Greek and sports culture on campus. On campuses such as UK, queerness is often marginalized and resides outside of normative culture and community. The act of embodying and reinventing queerness lies at the center of the queer identity in the contemporary context of political, social and academic influences. This research will explore how sapphic academics navigate performance, conversation, safety, inclusion, and change, documenting the negotiation of sexuality and gender in academia.

Abstract Name: An Atypical Presentation: Catatonia Mimicking Acute Stroke

Catatonia is a neuropsychiatric syndrome characterized by dramatic alterations in both movement and behavior. Catatonia is very common among older adults admitted to the hospital. However, it is frequently overlooked due to its potential to present similarly to stroke, particularly in those with prior central nervous system injury. This project explores how a multidisciplinary team used one geriatric patient's experience to determine if he had developed catatonia after having suffered a stroke and what providers need to be looking at when evaluating similar patients. The patient with a medical history of stroke secondary to a left middle cerebral artery stroke, hypertension, and hyperlipidemia, who experienced sudden confusion, disorganized behavior, urinary complaints, and difficulty speaking was evaluated urgently for acute stroke using brain CT and MRI scanning and EEG, which demonstrated chronic stroke changes and diffuse slowing but no evidence of new ischemia. The patient's clinical presentation included mutism, rigidity, poor response to commands, and decreased spontaneous movement and he received a high rating for severity on a standardized catatonia rating scale. Following a psychiatric recommendation for a lorazepam, the patient's gaze, rigidity, and verbal output all improved significantly within 48 hours and was discharged home on hospital day seven with complete resolution of his catatonic symptoms and a plan for ongoing outpatient follow-up. The case illustrates that while catatonia may develop suddenly and present with a new stroke-like presentation, it will typically be absent of focal neurological deficits or have evidence of new ischemic events on imaging studies increasing the risk of misdiagnosis and delayed treatment. Additionally, the case highlights the need for routine screening for catatonia in older adult inpatients presenting with behavioral changes and the need for collaborative efforts between hospitalists, psychiatrists, and neurologists to identify this condition and provide better outcomes for aging adults with neurovascular diseases.

Abstract Name: From Social Orphan to Political Subject: Racialized Humanitarianism in Transnational Korean Adoption

The essay examines how advocacy, power, and belonging intertwine within the context of transnational Korean adoption by analyzing my positionality as the Korean American student representative in the World Hug Foundation (WHF). Although I'm not an adoptee myself, my work with adoptees in mentoring sessions, workshops, and heritage trips placed me in a liminal position as a half-insider, neither fully an insider nor an outsider of the adoptee community. From this vantage point, I analyze the process of formation of discomfort or unbelongingness generated within the adoptees through the broad history of US empire, racialization, and humanitarianism. My interactions with the adoptees, adoptive parents, and adoptive agents are introduced alongside scholarly work by Pate (2014), Graves (2020), Kim (2010), and Kim (2024). The essay will determine how the concepts of racialized humanitarian sentiment, governance through love, and liminal belonging experienced by the adoptees are framed, addressed, and managed in real-life discourses regarding them. In this context, the adoptee heritage program works as a mechanism for the liminal belongings adoptees go through when adoptees navigate being seen as Korean in Korea while lacking language or cultural capital. The essay will demonstrate that transnational adoption was not a neutral care for the adoptees but a political action embedded in imperial histories, white normative family models, and global kinship regimes. Through my work as a non-adoptee advocate for the Korean American adoptees, the essay will closely reflect on the limitations of the transnational adoption process. Ultimately, the essay calls for shifting from viewing adoptees as 'social orphans' to highlighting them as epistemic and political agents whose voices must be central to research, policy, and practice.

Abstract Name: Impact of Blood Flow Restriction Cuff Design on Upper Body Exercise

Differences in cuff blood flow restriction (BFR) bladder design (single-chambered [SC-BFR] and multi-chambered [MC-BFR] systems) may influence exercise performance, perceptual responses, and cardiovascular outcomes. PURPOSE: To compare SC-BFR versus MC-BFR cuff design on acute performance, perceptual, and cardiovascular outcome measures during four sets of upper body bilateral biceps curl exercise to volitional failure using recommended application BFR guidelines. METHODS: In a randomized cross-over design, twenty-six healthy physically active individuals (22.6 ± 5.5 years old, 10 females; 25 reported engaging in resistance-exercise consistently) performed four sets of bilateral biceps curls to volitional failure using 20% of the 1-repetition maximum under three conditions: SC-BFR, MC-BFR, and a non-BFR control, post-exercise perceptual responses, and cardiovascular measures pre- and post-exercise. RESULTS: SC-BFR significantly reduced total repetitions compared to MC-BFR ($\Delta = -19.5$; $p = 0.002$; 95% CI = -34.9 to -3.9) and N-BFR ($\Delta = -48.7$; $p < 0.001$; 95% CI = -74.7 to -22.8). MC-BFR and N-BFR conditions demonstrated comparable performance in later sets. RPD was significantly higher in SC-BFR compared to MC-BFR and N-BFR ($p < 0.001$), while MC-BFR elicited lower RPE than SC-BFR ($p = 0.025$). Both SC-BFR and N-BFR conditions significantly reduced post-exercise diastolic blood pressure and mean arterial pressure, whereas MC-BFR did not. SC-BFR blunted post-exercise increases in carotid-femoral pulse wave velocity ($p = 0.328$), whereas the other conditions showed elevations ($p < 0.05$). CONCLUSION: SC-BFR induces greater repetition reduction and perceptual discomfort than MC-BFR, while MC-BFR demonstrates similar performance and comfort to N-BFR in later sets. SIGNIFICANCE/NOVELTY: Findings suggest cuff design plays a role in acute performance and perception-related responses, but not cardiovascular responses. The authors declare no conflicts of interest.

Abstract Name: All You Have in Life is Your Name: Uncovering My Family's History in America and Origins in Africa

The purpose of my research was to use any available documents to uncover the story of my family by working my way from my parents backward from one generation to the next. In this presentation, I will discuss the process and results of my ongoing genealogical research, which I began this past summer under the guidance of my faculty mentor. Through gathering and analyzing oral histories, family documents, legal records, and documents from digital databases, I was able to craft a narrative of several generations of my family history. As a senior citizen returning to pursue my educational goals, this project has been fulfilling in ways that I had not imagined. Through telling my family's story, I am able to offer an intimate understanding of the history of African Americans.

Abstract Name: Family Closeness and Familial Responsibilities Predicting Academic and Well-Being Outcomes for First-Generation Latine/x Students

Familism—a cultural value that emphasizes family closeness, loyalty, and support over one's own needs—is a collectivist value that plays a critical role within Latine/x communities. Research repeatedly shows that familism is protective for Latine college students in the transition to college. Yet, familial roles—the responsibilities and expectations a member holds in a family—play a more complicated role due to the cultural value mismatch (i.e., a psychological tension) that can play out in college. When universities value independence, students who come from more collectivist backgrounds, like Latine/x and first-generation (FG) college students, experience a cultural value mismatch due to the competing expectations from home and school. Cultural value mismatch has been linked to negative academic and well-being outcomes in separate studies. This study investigates the relationship between familism, family roles, and both academic performance and well-being. We conducted a secondary analysis of survey data collected from Latine/x FG college students during their first year in college (n=62) and we used a hierarchical regression analysis to test our hypotheses. We hypothesized that familism would predict higher academic performance (GPA), higher resilience, and lower stress. Although our hypotheses were not supported, we observed marginal trends. Higher self-family overlap marginally predicted higher GPA, and more family role engagement marginally predicted stress, but family role engagement did not moderate any of the predicted relationships. These insights can help inform future studies examining relationships between these variables and contribute to discussions about how college spaces can consider the role of family in creating resources that help Latine college students thrive academically and in their overall well-being.

Abstract Name: Effects of Energy Drinks on Heart Rate in Academic Settings

This research explores the effects of energy drinks on heart rate among students in academic settings. Energy drinks, often consumed for their stimulating effects, are widely used by students to enhance focus and combat fatigue during studying or examinations. However, the physiological impacts, particularly on heart rate, are not well-documented in the context of academic environments. This study aims to assess how the consumption of energy drinks affects heart rate variability and overall cardiovascular response during cognitive tasks in students. Using a controlled experiment, participants will be administered energy drinks containing 200 mg of caffeine and other stimulants, and their heart rates will be monitored at baseline, 10, 20, and 30-minute intervals while they engage in academic tasks. Participants will also complete a pre-and post-consumption survey in which they will self-report any signs of stress or jitteriness. Results from other experiments related to energy drinks suggest that energy drinks lead to a significant increase in heart rate, with variations observed across different subgroups based on factors such as age, gender, and habitual caffeine use. The study further investigates the implications of these cardiovascular changes on academic performance, stress, and cognitive function. Findings aim to provide a deeper understanding of the physiological consequences of energy drink consumption in students and contribute to informed

recommendations regarding their use in academic settings. This research highlights the need for greater awareness of the potential risks associated with these beverages, especially in environments where mental performance is critical, and underscores the importance of promoting healthier alternatives for cognitive enhancement.

Abstract Name: The Role of Middle and Hind leg in Stink Bug (*Halyomorpha halys*) Gait: Insight from Induced Autotomy

The voluntary loss of a limb is known as autotomy, which is a common defensive mechanism among arthropods, allowing them to escape predation or captivity. Although autotomy can be beneficial, it often compromises locomotion by alternating stability, gait, and propulsion. A hexapod uses an alternating tripod, the removal of a single leg could disrupt this coordinated pattern. *Halyomorpha halys*, known as the brown marmorated stink bug, uses this alternating tripod for locomotion. In this study, we examined how induced autotomy of either a hind limb or middle limb affects forward velocity, coordination, and overall gait stability in stink bugs. Using high-speed camera recordings and 3D reconstruction in Argus allowed us to measure changes in stance patterns, velocity, and gait coordination pre- and post-autotomy. Preliminary data have shown that forward velocity decreases after the removal of either the hind or middle limb. Despite predictions, removing the middle limb did not significantly alter coordination, and individuals did not show a shift to an alternative walking pattern. These preliminary findings suggest that losing any limb will cause a decrease in propulsion, but middle limbs may not play such a significant role in coordination and stability as previously hypothesized. Further data collection is needed to support these early trends and further evaluate how individuals modify their locomotion after autotomy.

Abstract Name: Magic or Miracle? Examining the Conflicting Rhetoric Around Early Christian Iconography from Ancient Rome

Between the years 300 and 500 AD, the Romans produced a collection of gold-glass medallions depicting Jesus holding a religious tool while performing his miracles. The nature of this object has been widely debated due to its absence from traditional Biblical stories, leaving the interpretation of the object itself up to broader social and cultural contexts. Naturally, the ability for varied interpretations of these images have resulted in label conflicts. Considering the positions of museums as moderators between academia and the general population, label conflicts can cause misinformation amongst the millions of visitors the museums receive annually. For example, in the British Museum, the artifact is titled “medallion” and the technology held by Jesus is called “the rod of power” in the object description. The Metropolitan Museum has a near-identical artifact labeled “Gold Glass Medallion with Christ as a Miracle Worker” and the object is called a “wand” in their description. My research thesis aims to highlight the variations in iconographic labels across institutions like the British Museum, the Metropolitan Museum of Art, and the Vatican Museum. Using methodologies like historiography to analyze object files in their respective archives, I have been tracing

conflicting terminology throughout the written record to determine how museums decided on modern label selections. Once the terminology has been identified, I compare it against the religious environment in which the iconography emerged, as well as their archaeological, visual, and material contexts.

Abstract Name: Sister Sin and Spare Rib: Safety, Softness, and the Resilience of Womanhood.

This body of work explores the strength of feminine joy, the power of softness, and the resilience of womanhood through large-scale oil paintings and acrylic prints. The central guiding questions for the work are: How can I use paint and printing processes to emphasize the importance of feminine joy, the power of softness, and the inherent resilience of womanhood? Further, can these representations offer experiences of empowerment from collective patriarchal trauma? By considering womanhood through a lens of agency, safety and joy, this project counters narratives that render women's experiences ornamental or subjugated. Instead, the artist offers an alternative: a vision of womanhood in which vulnerability serves as an act of reclamation, healing, and collective strength. Feminine power is extended through the inclusion of Great Danes in the artwork. No longer symbols of male ownership or domesticity, the dogs embody sacred protectors. They mirror the emotional states of the women they accompany while evoking mythic resonance, from the mother wolf of Roman lore to witches and their familiars. Rather than focusing solely on the historical oppression inflicted upon women, the work acknowledges its role in women's lives while highlighting a reciprocal force: joy as resistance. By celebrating women's relationships, via their friendships, self-love, or communal care, the paintings reclaim agency over the narrative of womanhood. Broaching such a subject is deeply personal to the artist yet universally relevant. Inspiration for the work stems from firsthand experiences while also drawing on a broader societal context in which women's voices are continually diminished. The artist asserts that in the joy and resilience shared between women, there exists a network of strength, from which all may draw and contribute to.

Abstract Name: Evaluating the Role of NAB2 Phosphorylation in its Liquid-Liquid Phase Separation

The protein NAB2 plays an important role in regulating gene expression in cells and affects a variety of cell behaviors including differentiation, proliferation, and apoptosis. However, the mechanisms that control NAB2 activity are not well understood. Recent data in our lab demonstrates that NAB2 undergoes liquid-liquid phase separation (LLPS), which is phenomenon increasingly appreciated for its roles in regulating a variety of proteins and cellular events, including transcription factors and gene expression. LLPS is a biophysical event in which specific proteins separate from their surrounding liquid environment, forming their own more concentrated, yet still liquid, phase in the form of condensates. LLPS is mediated through multivalent interactions between unstructured regions of proteins, referred to as intrinsically disordered regions (IDRs), and computational analysis predicts that NAB2 has multiple IDRs. In addition, LLPS by

proteins can be affected by post-translational modifications such as phosphorylation (adding a phosphate group to serine or threonine amino acid residues) and our lab has identified 10 putative phosphorylation sites on NAB2. Thus, the aim of this research is to determine whether NAB2 phosphorylation plays a role in regulating its LLPS. Through recombinant DNA technology, the potential phosphorylation sites (all serine or threonine residues) of NAB2 fused to GFP (NAB2-GFP) will be mutated to an alanine using site-directed mutagenesis on a pNAB2-GFP expression construct to block phosphorylation. The mutant constructs will be transfected into human cells grown in culture and NAB2 LLPS, based on the formation of condensates, will be evaluated using fluorescence microscopy. Thus far, five mutant constructs have been generated; however, more mutant constructs are required to determine dephosphorylation exhibits any alterations in droplet formation, which will clarify the potential role of NAB2 phosphorylation in regulating its LLPS behavior.

Abstract Name: Zero2Neuro: A Zero-Code Solution for Deep Neural Networks

Machine learning (ML) is becoming used widely in multiple domains of science and yet many domain scientists struggle with creating ML-based models, running experiments, and evaluating the results. One of these forms of machine learning is deep neural networks, which are used across scientific domains for their ability to classify images, perform speech recognition, detect anomalies, and many more tasks. To address the problem of helping domain scientists utilize deep neural networks we developed Zero2Neuro, a tool-kit that provides a minimal code solution to creating, training, and evaluating deep neural network-based models. Zero2Neuro aims to help domain researchers with little to no coding experience have the ability to utilize these models in their research and to help reinforce good practices when developing these pipelines. The toolkit allows users to specify experiment, data, and network configuration details via three configuration files to develop a machine learning pipeline. We also include multiple examples of best practices for use on personal computers, supercomputers, and Jupyter Lab in a GitHub repository as well as in-depth documentation. Work is ongoing with the toolkit as we are currently introducing Zero2Neuro to domain experts for use in their research and incorporating their feedback into the development for our planned full release by the end of the year.

Abstract Name: Impact of health disparities on cervical cancer outcomes among African American women

Impact of health disparities on cervical cancer outcomes among African American women
Mentor Sirjani Hedieh H, PhD, MDBryanna Seymore
Background: Cervical cancer outcomes remain unequal in the United States, with African American women experiencing higher mortality and later stage diagnoses compared to

other groups. The primary research question guiding this review is: How do health disparities affect cervical cancer outcomes among African American women? Understanding these disparities is essential for developing strategies that improve early detection and survival. Method: A structured literature search was conducted in January 2025 using PubMed to identify peer reviewed studies published from 2021 to 2024. The search focused on cervical cancer, screening, prevention, and health outcomes among African American women. Duplicate articles were removed, and titles and abstracts were screened for relevance. Studies were included if they focused on African American women and reported findings related to screening behaviors, follow up care, health care experiences, or clinical outcomes. Studies that did not meet these criteria or examined unrelated populations were excluded. After full text review, fifteen studies were included in the final analysis. Results: The search initially identified ninety five articles. Seventy were excluded during title and abstract screening for not meeting inclusion criteria, and ten additional studies were excluded after full text review. The fifteen included studies consistently reported disparities in screening access, follow up care, patient trust, communication with providers, and overall clinical outcomes. Conclusions: The literature demonstrates that health disparities continue to significantly influence cervical cancer outcomes among African American women. Culturally informed, accessible, and targeted strategies are needed to reduce these gaps, improve early detection, and enhance long term survival. Keywords: Cervical cancer, African American women, disparities, screening, outcomes

Abstract Name: ADHD and Autism affected by a sense of identity in oneself and how one is perceived in society.

How do the effects of social pressure on Autism and ADHD create disrupted personalities and a greater need to conform for societal comfort? Articles such as “Autism is Me” and “Struggles of an AuDHD Student” help in understanding the struggles of individuals facing stigma with these conditions. Artists such as Van Gogh, Da Vinci, Warhol, and Picasso are important inspirations on the stigma around individuals on the spectrum and/or with ADHD in art during their time. Personally, being diagnosed with Kanner’s Syndrome (Classic autism) and combined type ADHD gave a sense of why there were struggles with identity and social life into adulthood, with the reality of being “normal” in society becoming more evident with each interaction and stronger with new norms every day. In the film art presented, clips of home videos, glitched footage, and personal/conversational dialogue are used to showcase the external and internal struggles with identity under pressure. There will be intentional discomfort to create the reality of how society can and will force conformity upon people who do not “fit” the standards. The result is to generate open curiosity towards ADHD and Autism, with the intention of breaking stigma and pressure towards identity. Addressed in future pieces will be different struggles faced culturally and ethnically by individuals for a diverse series. This piece fits into my portfolio as it is based on self-identity and personal growth. This will be part of a future series on greater awareness, intentionally diversifying each piece based on individuals from other countries.

Abstract Name: Nutrition incentives and shopper behavior: Survey insights and behavioral modeling from a SNAP farmers market match program

Low fruit and vegetable (FV) intake increases the risk of chronic disease, and low-income households participating in the Supplemental Nutrition Assistance Program (SNAP) continue to face cost and access barriers that limit FV consumption. Nutrition incentive programs aim to reduce these barriers by making FV purchases more affordable for SNAP participants. We analyzed eight years of survey data from a SNAP nutrition incentive program (2018–2025; N = 1,071) using descriptive analyses and Poisson and logistic regression to assess shopper experiences and engagement at a Wisconsin farmers market. Most participants reported eating more FV (90%), trying new foods (63%), and saving money on groceries (85%) as a result of the program. Nearly all respondents (93%) described the market as welcoming, although some noted barriers such as transportation limitations (18%), weather (23%), and limited hours (13%). Higher incentive redemption was significantly associated with increased visit frequency, with each additional \$10 in incentives corresponding to approximately 17% more visits ($\beta = 0.016$, $p < .001$). Visit frequency also predicted next-season participation, with each additional 2024 visit increasing the odds of returning in 2025 by 60% (OR = 1.60, $p = .011$). These findings suggest that incentives may support a behavioral pathway in which affordability encourages more frequent attendance, which in turn promotes sustained engagement and improved FV access for low-income households. This work highlights both strengths and persistent barriers within the program and provides insights to inform the development of equitable and accessible statewide nutrition incentive strategies.

Abstract Name: How Black People Talk to God: Ritual, Memory, and Spiritual Agency in Contemporary Black Expression

This project investigates the ways Black people communicate with the divine through everyday ritual, language, sound, and embodied practice. I explore spiritual communication as a multidimensional practice shaped by ancestral memory, domestic space, community structure, gendered labor, and the ongoing struggle for identity, joy, and rest. My research draws heavily from the iconography of the Black church (particularly African American churches), including architecture, sermons, metaphors, parables, and the emotional atmosphere created through communal worship. The church functions as a space of community, spiritual grounding, and cultural affirmation, offering a sense of connection. During Sunday service, praise and worship is expressed through instruments, hymns, shouting, dance, and improvisation. I also study the significance of fashion in the church, where dressing becomes an act of dignity, self-presentation, and resistance. Historically, Sunday service offered one of the few spaces where Black people could move through the world freely and momentarily step outside the constraints of forced labor and discrimination. My work also considers Blues and R&B as forms of release, storytelling, and celebration. These musical traditions translate the experiences of everyday life into sound, carrying both the pleasure and the hardship of living under an oppressive system. The artists Carrie Mae Weems, Kara Walker, and Nina Simone influence and shape my art practice. My project responds to the histories of the Black church, the Civil Rights Movement, the Trans Atlantic Slave Trade, and the ongoing need for redemption, healing, and creative expression. By analyzing my lived experience, oral history interviews, sonic and visual culture, and

performance, I examine how worship becomes a language of survival. The resulting body of work includes mixed media collage, photography, videography, painting, dresses, poetry, installation, and music that illuminates Black spirituality as a living, shifting conversation that moves across generations.

Abstract Name: Increasing Lycopene Production in Green Zebra Tomato Using CRISPR/Cas9 Gene Editing

CRISPR/Cas9 has become an increasingly popular method for gene editing in fruit crops. In this experiment, CRISPR/Cas9 is used to increase lycopene production in the Green Zebra variety of *Solanum lycopersicum*. A point mutation is used to knockout the Stay Green (SGR1) gene causing an overexpression of the Phytoene Synthase 1 (Psy1) gene. This method consists of seed sterilization, cotyledon infection using *Agrobacterium tumefaciens* EHA105, and tissue cell culture. A mutation causing increased lycopene production has several implications. The increase in lycopene production from the knockout of the SGR1 gene will suggest that the Green Zebra tomato variety has the same SGR1-Psy1 gene relationship as the standard *Solanum lycopersicum* tomato. A successful mutation will also show that CRISPR/Cas9 is not only an efficient way to increase nutritional value in a tomato, but it will also suggest that CRISPR/Cas9 is a viable way to correct mistakes brought about through the domestication of the tomato.

Abstract Name: Identifying Biomarkers for Early Detection of Endometriosis: Addressing Diagnostic Delays in Women's Health

Millions of women worldwide are affected by endometriosis, a condition that is frequently misdiagnosed or underdiagnosed due to its broad symptom range and overlap with other disorders. Endometriosis occurs when tissue similar to the uterine lining grows outside the uterus, leading to inflammation and severe pain. This condition can also cause painful periods, abdominal discomfort, and chronic pelvic pain. Although endometriosis has been described in older medical literature (1690), it was not identified under a microscope until 1927, which contributed to a long history of misunderstanding and inconsistent recognition. Research on endometriosis has led to the development of some non-invasive options for patients, and there has also been an increase in clinical trials. However, these non-invasive options are currently very limited, and a definitive cure remains elusive. The research thus far has concluded that lifestyle adjustments such as exercise, over-the-counter (OTC) pain relievers, and hormonal birth control can help with pain management of symptoms. Although this represents progress, these approaches manage symptoms rather than identifying the underlying causes or supporting early diagnosis. After reviewing current peer-reviewed research, this project will focus on evaluating potential biomarkers to support earlier detection of endometriosis and accurate diagnoses. The main objective is to address the factors contributing to delayed diagnosis and improve overall understanding of endometriosis. Moving forward, this project will explore strategies for increasing public and clinical

awareness while also examining blood, urine, and tissue biomarkers that may support earlier and more reliable detection.

Abstract Name: Effects of Psilocybin on Cognitive Flexibility Using a Naturalistic Attentional Set-Shifting Task in Rats

Substance use disorder is a global crisis, impacting millions of people worldwide. One of the key factors in recovery is cognitive flexibility, which is our brain's ability to adjust and shift strategies when situations change. Psychedelics like psilocybin have shown therapeutic potential by enhancing this flexibility. However, most previous studies use artificial operant tasks like lever pressing that don't reflect how rats naturally behave or learn. My project employs an instinctive Attentional Set-Shifting Task (ASST), which involves burying food in a medium and requiring rats to discriminate between different stimuli. This provides a more realistic model for understanding how psilocybin may affect learning. All 24 Sprague-Dawley rats were trained to dig in bowls filled with different mediums and odors to obtain a food reward. After successful training, each rat was injected with either psilocybin or saline. They were then tested at two time points: 24 hours and one week post-injection. The testing session consisted of series of progressively harder tasks called set-shifting tasks, during which rats were presented with different combinations of sensory cues. Performance of rats was measured using trials to criterion, number of errors, and latency to dig. A notable difference was observed in the intradimensional reversal task one week post injection. Rats that received psilocybin required fewer trials to reach the correct response compared to those that received saline. This suggests that psilocybin may enhance reversal learning, a measure of cognitive flexibility. Interestingly, these effects appeared one week later and not immediately after administration. This points to psilocybin's longer-term neural adaptations, rather than a short-term boost in performance. Ultimately, this research helps bridge the gap between animal and human studies, highlighting how psychedelics may improve cognitive flexibility and their future use in treating substance use disorders.

Abstract Name: Sex differences in the Gut Microbiome from Human Microbiome Project 16S rRNA data

In maintaining human health and regulating metabolic processes, the gut microbiome has been revealed to play a critical role. However, sex-related differences in microbial composition vary significantly across studies. Prior research has identified associations, but the influence of other factors such as hormonal concentration, genetic responses, and immune responses still remain under investigation. In this project, we analyzed publicly available 16s rRNA gene sequencing data from the NIH Human Microbiome Project (HMP16SData)1, focusing on stool samples from two variable regions (V1-3 and V3-5) to examine microbial variation by sex. Using the phyloseq R package, we performed alpha diversity analysis (Observed richness, Shannon index) and beta diversity analysis (Bray-Curtis distances with PCoA) to assess the microbial

community structure. Furthermore, we performed differential abundance analysis with DESeq2, identifying several genera that significantly differed between males and females. Preliminary results indicate distinct sex-based differences in microbiome composition with genera such as Prevotella, Lactobacillus, Ruminococcus varying in relative abundance across these sexes. To evaluate the predictive capability, we implemented a logistic regression by training samples and using genus-level microbial abundances to classify the samples by sex. Additionally, the model demonstrated measurable predictive accuracy, suggesting sex-specific microbial signatures can serve as a discriminative marker. The research contributes to a growing understanding of how sex influences gut microbiology. This will also lead the way for practical applications to be understood such as personalized dietary and therapeutic interventions, while theoretical contributions can advance knowledge of host-to-microbiome interactions.

Abstract Name: A Hybrid LLM-RAG Tutoring System for Adaptive, Step-By-Step Student Learning

AI tools are now widely used in college courses, but most systems still give students direct answers instead of helping them think through problems on their own. This limits opportunities for meaningful learning and self-regulated problem-solving. This project investigates how an AI-driven tutoring platform can be designed to guide students through step-by-step reasoning while adapting to their progress, rather than simply providing solutions. To address this problem, we developed a hybrid tutoring system that combines large language models, Retrieval-Augmented Generation (RAG), and real-time analysis of student interactions. RAG pipelines supply accurate course-specific context, and a lightweight classifier identifies the topic of each question to activate structured reasoning pathways. As part of this project, I implemented the data logging and topic-classification components and helped design the adaptive prompting framework. The system records how students interact with the tutor, common mistakes they make, and where they ask for clarification. These logs are being used to generate personalized review materials, targeted practice problems, and recommended reading based on each student's performance trends. The platform is currently being piloted in an undergraduate computing course at an R1 university using a mixed-methods evaluation. Quantitative analysis focuses on usage patterns and reductions in repeated errors, while qualitative data comes from student surveys and open-ended feedback. Preliminary results show growing use of the platform before major exams, along with a 17% decrease in repeated errors on logic-related tasks among early adopters. Students report that the step-by-step guidance helps them better understand problem structure and stay focused while studying. These early findings suggest that structured, adaptive AI tutoring has the potential to strengthen students' reasoning processes, improve conceptual understanding, and support more effective study habits across different course topics.

Abstract Name: Dissecting Non-Redundant Roles of BET Paralogs in T Cell Exhaustion

The BET family of proteins—including BRD2, BRD3, and BRD4—are epigenetic regulators that read acetylated histones and recruit transcriptional machinery to activate gene expression. Positioned at the intersection of chromatin structure and transcription, they influence cell identity, proliferation, and immune responses. Their broad regulatory roles have made BET proteins prominent therapeutic targets, particularly in cancer immunotherapy. Current research investigates pan-BET inhibitors that are used to “rescue” exhausted CD8⁺ T cells by restoring effector function. However, because current inhibitors act on all BET paralogs simultaneously, it has remained difficult to determine which specific proteins drive these immunological effects. To address this, we generated three transgenic mouse models with a dTAG and a HaloTag, in which BRD2, BRD3, or BRD4 can be selectively and rapidly degraded upon ligand treatment. We validated efficient degradation both ex vivo and in vivo, observing near-complete loss of predominant isoforms within hours. The HaloTag enabled us to perform live-cell imaging of the respective BET protein’s condensates. Using chronic ex vivo activation protocols, we developed exhausted-like CD8⁺ T cells and confirmed phenotypes via flow cytometry. Acute depletion of individual BET paralogs during exhaustion produced distinct changes in both cell-surface markers and transcriptional programs. We were able to use the HaloTag to visualize exactly how the condensates changed and/or degraded. RNA-seq revealed paralog-specific regulation of key immune genes including *Ifn-γ* and *Tnf-α*. These findings demonstrate that BET proteins are not functionally redundant and instead exert paralog-specific control over T cell transcriptional programs. This work highlights the potential of paralog-targeted BET modulation as a more precise immunotherapeutic strategy than existing pan-BET inhibition.

Abstract Name: HPA Axis and its Relation With the Body- Understanding Biology and Psychology’s Mutual Influence

This literature review examines the hypothalamic-pituitary-adrenal (HPA) axis and how it regulates both stress and recovery in reconstructive surgery, focusing particularly on the biochemical, enzymic, and epigenetic processes whereby psychological distress impacts the healing process via cortisol, both as a facilitator and inhibitor thereof. Synthesizing multiple peer-reviewed studies, this research review categorizes current research into five interrelated domains: physiological stress responses, local versus systemic cortisol regulation, enzymatic control, epigenetic modulation, and personalized treatment models. The literature will draw on various scholarly articles and will categorize various pieces of current research regarding this topic among the following five areas: • Responses to stress • Local and systemic regulation • Enzymic regulation • Epigenic regulation • Treatment approaches Throughout various studies, stress was indicative to stimulate the HPA axis, resulting in an increase in cortisol levels and a suppression of the production of pro-inflammatory cytokines, which are crucial to the healing process. The influence of psychological stress on a delay in the healing process by as much as 40% was highlighted by a study by Gouin & Kiecolt-Glaser (2011). Cohen et al. (2009) and Ajjan et al. (2022) further confirmed that the regulation of cortisol production by enzymes, including 11β-HSD1, largely affects the healing process. Epigenetic studies by Willmer et al. (2022) and Miller et al. (2025) identified that stress, as well as exercise, affects the methylation patterns of FKBP5, which, in turn, affects the sensitivity to glucocorticoids. The article concludes that the process of recovery following reconstructive surgery should be viewed as a psychoneuroendocrine, rather than a strictly mechanical, procedure. Tailor-made therapies involving cortisol enzyme blockade, stress management prior to surgery, and genomic analysis may allow for maximized tissue healing and results, by relating endocrine, psychological, and genetic frameworks, providing a diverse perspective involving mind, hormone, and healing.

Abstract Name: The Role of Intellectual Humility, Trauma, and Psychopathy in Gun Violence: Understanding Their Implications on a Path Toward Prevention

Gun violence has become a threatening phenomenon that has been affecting the lives of Americans nationwide. Two main traits that show a predisposition towards gun violence are psychopathy and trauma. We focused on the interaction between childhood trauma and psychopathy and analyzed how intellectual humility affects this relationship. When looking at the relationship between these two traits, we found that psychopathy had a positive relationship with trauma ($r = 0.75$, $p < 0.001$). This means that there is a highly reactive at-risk population (traumatized psychopaths) that is more likely to use guns for violent purposes. The findings also confirm our hypothesis that psychopathic traits have an inverse relationship with intellectual humility. This further supports the idea that increasing IH could have the opposite effect of decreasing psychopathy. A moderation analysis showed that the relationship between trauma and psychopathy was moderated by intellectual humility $F(3, 157) = 74.16$, $p < .001$. This lowers a key predisposing factor for gun violence, psychopathy, and diminishes the reactivity of a highly at-risk population of traumatized individuals exhibiting psychopathic tendencies. So, systematically teaching concepts associated with intellectual humility in schools could decrease the likelihood of traumatized psychopaths committing an act of violence. IH courses include implementation of projects and teaching styles that emphasize passion for information rather than external benefits. Additionally, a subscale of intellectual humility, had a positive relationship with psychopathy ($r = .38$, $p < 0.001$). This means that psychopathic individuals are more likely to change their minds. So, persuasive methods may be used to reason with psychopaths and prevent them from pursuing gun violence. This study utilizes novel relationships to help understand and address those who are prone to gun violence. These promising results could be used in the future to analyze methods to intervene against aggressive behaviors like gun violence in schools.

Abstract Name: A Feedback Loop Control to Automate Cold Atmospheric Pressure Plasma (CAPP) Based Additive Manufacturing

Currently, nanoparticle annealing based additive manufacturing process requires high temperatures, making them unsuitable for a broad range of applications. By lowering the temperature and developing a process to use Cold Atmospheric Pressure Plasma (CAPP) for annealing, many more doors are opened to a wide range of materials, films, and environments for space, communication, and microelectronics. CAPP-based additive manufacturing technology is continuously evolving, making projects like nanoparticle annealing more feasible. In this work, we designed a CAPP jet printer assembly consisting of a 0.25-inch outer diameter glass tube connected to a 3D printing nozzle. The flow of Argon gas in the tube is maintained by a mass flow controller. The plasma jet is created by applying a high voltage ($\sim 10\text{kV}$, 0.01 A) to copper electrodes on a glass tube. The current work highlights the development of a Python and NI LabVIEW-based digital interface

to automate our CAPP jet-based plasma printing process by designing a control system with a feedback loop for the power supply, pressure monitor, Mass Flow Controller, and x-y-z stage. The data from the power supply and MKS mass flow controller were acquired using an NI USB 6001 I/O device. The program integrates the acquisition, in-situ analysis, and real-time data visualization, apart from allowing more access to end users. Moving forward, we aim to create a web-based portal to remotely control the mass flow controller and 3D printer.

Abstract Name: Relationships Between Sleep, Pain, and Physical Activity in Idiopathic Generalized Epilepsy

People with idiopathic generalized epilepsies (PwIGE) represent about 20% of all epilepsies but comprise <1% of epilepsy research. Many PwIGE lead sedentary lifestyles which may contribute to sleep disruptions and increased pain; these all negatively impact quality of life (QoL), but their relationships remain unclear. We investigated associations between physical activity levels, sleep quality, and pain levels in PwIGE. We hypothesized that PwIGE will exhibit decreased levels of physical activity associated with decreased sleep quality and worse pain, and a negative association between sleep quality and pain. 68 PwIGE (43 female, mean age 31.63), completed assessments of QoL (Short Form-36 (SF-36)), sleep (Pittsburg Sleep Quality Index (PSQI)) and physical activity (Leisure Activity Total Score (LATS)). PwIGE were stratified into two groups: 36 (53%) self-reported as seizure-free (NoSz) and 32 (47%) reported experiencing seizures (Sz) within the last six months. Two-sample t-tests compared seizure groups. Pearson correlations determined relationships between LATS, PSQI and SF-36-Pain scores in combined and separate seizure groups. Seizure groups did not differ in age, sex distribution, epilepsy onset age, or epilepsy duration (all $p > 0.05$). Mean scores were significantly worse for Sz compared to NoSz on SF-36-Pain ($p = 0.011$) and LATS ($p = 0.007$), and no significant differences on the PSQI ($p = 0.256$). There were significant correlations between PSQI and SF-36-Pain in the combined group ($r = -0.42$; $p < 0.001$) and in the NoSz ($r = -0.41$, $p = 0.015$) and Sz ($r = -0.42$, $p = 0.016$) groups. LATS was not significantly correlated with PSQI or SF-36-Pain (all $p > 0.05$). Contrary to our hypothesis, self-reported physical activity level was not associated with either sleep quality or pain levels. However, significant correlations of poor sleep quality with increased pain regardless of seizure control status showcase a relationship that warrants further study in PwIGE. Future directions may include physiological measures of physical activity, sleep, and pain for further examining such effects.

Abstract Name: Proteomic Changes in HDL following Spinal Cord Injury

In Spinal Cord Injury (SCI), cholesterol homeostasis is significantly disrupted by initial damage to cholesterol-rich tissue, chronic inflammation, and systemic dysregulation. This metabolic shift increases the risk of cardiovascular disease and hinders SCI recovery. High-Density Lipoprotein (HDL) is best understood for its role in reverse cholesterol transport and cardioprotection based on the amount of cholesterol it carries. However, current research suggests that the composition of HDL is a stronger predictor of cardioprotection than HDL-cholesterol (HDL-C) quantity alone. The distinction of quality versus quantity is critical in the context of SCI, as this injury alters HDL-associated proteins even as HDL-C levels decrease. HDL has a heterogeneous population that aids in anti-coagulation, anti-inflammation, and immune response. Since HDL has a host of responsibilities, dysregulated HDL not only affects cholesterol transport but also other processes. To elucidate how proteomic changes impact HDL function, we performed Gene Ontology (GO) analysis to identify upregulated and downregulated biological pathways before and after injury. Our gene ontology analysis categorized the proteins into four primary families: cholesterol transport, immune function, coagulation, and inflammation. Our study found a downregulation of cholesterol transport-related pathways, indicating an increased risk of atherosclerosis. Conversely, there was upregulation of immune function and coagulation pathways. These results illuminate HDL's shift toward a prothrombotic and proinflammatory state following SCI. The upregulation of coagulation in the absence of vascular injury increases thrombotic risk, such as stroke. Moreover, the overactive immune response supports mechanisms of foam cell formation and secondary injury seen in SCI patients. To conclude, dyslipidemia following SCI is primarily a disruption of the lipoprotein proteome rather than a purely quantitative decrease of HDL-C. Consequently, therapeutic strategies should prioritize modifying HDL protein composition to restore homeostatic function, rather than solely increasing HDL-C levels, to improve long-term cardiovascular and neurological outcomes in SCI patients.

Abstract Name: Parent Involvement in Immigrant Families: Impacts on School Engagement and Academic Achievement.

This study examines the relationships between parental involvement, school engagement, and adolescent well-being and academic performance, with a particular focus on immigrant families. Parental involvement is widely recognized as a critical factor in shaping students' educational trajectories, yet its influence within immigrant households remains underexplored. Guided by self-system theory, this project conceptualizes parental involvement as a multidimensional construct home-based support, school-based participation, and academic socialization and investigates its direct and indirect effects on academic achievement and psychological well-being. Using a quantitative design, we will integrate validated survey instruments with report card data and interviews with parents and students to capture cultural nuances and educational aspirations, including whether discussions about higher education occur in the household. Our conceptual model tests mediation, where behavioral and emotional school engagement explains the link between parental involvement and child outcomes, and moderation, where ethnicity and socioeconomic status (SES) shape these associations. SES is expected to influence both the level and effectiveness of parental involvement, as families with greater resources may have more opportunities to engage, while lower-SES families may rely on home-based strategies that still significantly impact engagement. Anticipated findings include evidence that academic socialization such as communicating educational expectations plays the strongest role in enhancing engagement and achievement while mitigating stress and depressive symptoms. By incorporating

micro-level factors (family practices and aspirations), mezzo-level influences (school climate and engagement), and macro-level contexts (SES and cultural norms), this study seeks to identify culturally responsive strategies that support both academic success and mental health. Ultimately, the project aims to inform educators, and community organizations about effective interventions that promote equity and holistic well-being among diverse student populations, while highlighting the importance of family-school partnerships in reducing achievement gaps and fostering pathways to higher education.

Abstract Name: Manipulation for Profit: The Economic and Public Health Consequences of Tobacco Industry Influence

The tobacco industry spends tens of millions each year lobbying the federal government, even as tobacco-related diseases cost the U.S. hundreds of billions in healthcare spending. This imbalance shows how corporations use economic power to shape policies that protect profits over public health. Sam Kean's *The Icepick Surgeon* illustrates how similar patterns recur throughout history: institutions have often used scientific language to justify harm while defending their own interests. Although scholars have examined lobbying expenditures and regulatory capture, we still lack a clear understanding of how tobacco companies coordinate economic influence with manufactured scientific doubt to manipulate policy outcomes. Our research investigates how tobacco corporations use lobbying expenditures, revolving-door employment, and industry-funded research to influence policy decisions. We connect these strategies to the dynamics Kean describes, where scientific authority becomes a tool for maintaining power. Our literature search draws on databases such as JSTOR and policy documents and campaign finance records from federal government websites. Key search terms included "tobacco lobbying," "regulatory capture," "corporate influence," and "policy manipulation." Our analysis identifies three strategies companies use to shape policy. First, directing political contributions toward legislators on health committees to obstruct restrictive regulations. Second, funding research that creates uncertainty about tobacco's harms, weakening scientific consensus and delaying public health protections. Third, cultivating insider relationships through revolving-door hiring, recruiting former regulators as lobbyists to shape rulemaking from within. Across these tactics, the industry frames regulation as an economic threat rather than a public health necessity, echoing Kean's accounts of institutions that use authority and strategic messaging to shield harmful practices. At the same time, grassroots advocacy and evidence-based policy initiatives are pushing back. Understanding these strategies shows how economic power enables systemic manipulation and informs potential reforms such as campaign finance regulation, limits on revolving-door employment, and independent research funding.

Abstract Name: Why Wait? Examining Situational Predictors of Delaying in the Marshmallow Test: A Meta-analysis

The classic marshmallow test has been viewed as a powerful assessment of young children's ability to delay gratification and exert self-control. This is partly due to its simplicity: children are given a singular choice between a less preferred reward immediately or wait for a more preferred reward after a set amount of time. On the surface, the task appears to assess self-control. The test is also popular because of findings that it predicts a range of later-life outcomes, such as academic performance and behavioral conduct. However, researchers have found that contextual factors significantly influence children's delay-wait behavior. These findings, vital as they are, presume that the marshmallow test is a fundamentally sound measure of delay behavior rather than something else. We consider whether this is a reasonable assumption. A meta-analytical approach was employed to investigate the effects of procedural variations on the results of the marshmallow task and its attrition. The study compiled ~110 articles using three databases: PsycInfo, ERIC, and ProQuest Central. Articles that passed screening are being coded for their sample characteristics, procedural characteristics, and effect sizes to determine variations in results. Consistent with best practices in meta-analysis, we are also taking steps to identify the grey literature, for example, by reviewing conference proceedings and soliciting studies via listservs. The coded data will subsequently be analyzed through a meta-regression. We expect the study to advance research and theory related to the marshmallow test. By clarifying key issues with the task, we raise important questions about measurement and interpretation that have not yet been addressed. We also expect the research to prompt procedural improvements that reduce ambiguity and noise in wait-time measurement. The empirical results will provide much-needed clarity concerning the impact of procedural variations on wait times and attrition, however they turn out.

Abstract Name: Chemogenetic Modulation of Glucagon-like Peptide-1 Producing Neurons in the Brainstem Influences Cocaine Reward Processing

Glucagon-like peptide-1 (GLP-1), known for its role in glucose regulation and appetite control, has emerged as a potential modulator of reward pathways, offering promise in understanding the neural mechanisms of substance use disorders, including cocaine use disorder. With over two million regular cocaine users in the U.S. and its contribution to 20% of drug overdose deaths, understanding the role of GLP-1-producing neurons (Gcg-expressing neurons) can guide therapy development. Previous research identified GLP-1 receptors and Gcg neurons in the caudal nucleus of the solitary tract (NTS), a critical brain region involved in reward processing and interoception. However, we used Fos staining in Gcg-GFP reporter mice to demonstrate that while cocaine broadly activates the NTS, it does not significantly activate Gcg neurons, contradicting previous reports. This study investigates whether chemogenetic modulation of Gcg-NTS neurons influences cocaine-seeking behavior using a conditioned place preference (CPP) paradigm. Gcg-Cre mice received bilateral NTS injections of excitatory (hM3D-Gq), inhibitory (hM4D-Gi), or control (mCherry) viral vectors. Following recovery, mice underwent cocaine-conditioned place preference and reinstatement testing after a cocaine prime (20 mg/kg). Neuronal activation was quantified via Fos immunohistochemistry. As a positive control for DREADD functionality, a feeding suppression and refeed assay was conducted, and hM3D-Gq mice showed a significant reduction in food intake at 1-hour post-DCZ administration, confirming successful activation of Gcg-NTS neurons. Chemogenetic manipulation of Gcg-NTS neurons did not produce statistically significant effects in cocaine-conditioned place preference. This suggests that cocaine reward may involve more complex circuits than previously appreciated, beyond the contribution of Gcg-NTS neurons. Gcg-NTS neurons robustly influence feeding, supporting a homeostatic role, but their contribution

to cocaine-context learning remains unclear. Ongoing behavioral analysis and validation of viral targeting will clarify whether these neurons modulate cocaine reward.

Abstract Name: Migrant Labor in the Gulf States: Ideology, Geopolitics, and Global Perceptions

This research examines how major international media outlets frame the treatment of migrant workers in Gulf states. While scholars have compellingly documented labor exploitation and its dramatic consequences in these states, little attention has been given to how international audiences engage with this issue. Media coverage, particularly English-language reporting targeting Western audiences, plays a significant role in shaping global awareness and public understanding of human rights issues in Gulf states. By conducting a comparative media analysis of articles from The Guardian, Fox News, and Al Jazeera between 2010 and 2025, this study investigates how each outlet portrays Gulf governments, migrant workers, the causes of their exploitation, and accountability for labor abuses. Preliminary findings suggest the following: Fox News emphasizes Gulf states' reform efforts and the positive implications of these reforms; Al Jazeera highlights recruitment corruption and pandemic-era hardships; and The Guardian centers worker testimonies and systemic exploitation. By combining discourse analysis and narrative analysis methods, the study deciphers the power dynamics and ideologies that inform seemingly "objective" reporting. These methods reveal how tone, imagery, and framing strategies influence whether migrant workers are depicted as economic contributors, victims of structural injustice, or individuals with agency and personal stories. The main argument is that media framing of migrant labor issues in Gulf states is primarily shaped by ideology and geopolitics. This analysis contributes to critical media studies literature and scholarly discussions on the global political economy of migrant labor and racial capitalism. In doing so, it offers a global perspective on migrant labor and expands our understanding of inequality, racism, and labor in Gulf states and beyond.

Abstract Name: Microbial Changes upon Chemotherapy Induced GI Toxicity in Colon Cancer Patients—a Population Study

Background: Growing evidence supports the idea that the microbial metabolism of drugs, and therefore the host microbiome composition, can modulate the toxicity of chemotherapeutic agents. Such microbial activity can directly impact the treatment efficacy of cancer patients, as well as disease development and progression. Irinotecan is a broad-spectrum cytotoxic anticancer agent that induces cell death in rapidly dividing tumor cells and disrupts the gut microbiome. This microbial dysbiosis is clinically significant because certain bacteria produce β -glucuronidases, enzymes that convert irinotecan's inactive glucuronidated metabolite, ethyl-10-hydroxy-camptothecin (SN38G), back into its active form (SN38). The resulting local reactivation

contributes to mucosal injury and diarrhea, which occurs in 50–80% of patients and often necessitates dose delays, dose reductions, or hospitalization. While treatment with cytotoxic agents can induce changes in the composition, structure, and function of the gut microbiome, whether an individual's gut microbiome composition directly influences response to irinotecan treatment remains to be determined. Objective: The goal of this project is to investigate alterations in microbiome composition in colon cancer patients experiencing chemotherapy-induced gastrointestinal toxicity. Design methods: We will conduct a systematic review of mouse and human gut microbiomes profiled with 16S and shotgun metagenomic sequencing exposed to irinotecan and other cytotoxic chemotherapeutic agents. PubMed, Embase, and additional databases will be searched for relevant studies, with inclusion restricted to publications reporting original data deposited in publicly accessible repositories. Microbiome composition will be compared across available groups, such as healthy versus cancer patients and individuals with or without diarrhea, using relative abundance changes and diversity metrics (alpha and beta diversity). Conclusions: From these analyses, we aim to identify microbial signatures associated with chemotherapy-induced gastrointestinal toxicity and assess whether individual gut microbiome composition correlates with response to irinotecan, providing preliminary evidence for a potential direct influence.

Abstract Name: Multifaceted response of microglia in a cuprizone model of demyelination

Multiple Sclerosis (MS) is an autoimmune disease, characterized by myelin loss, neuroimmune response, and neurodegeneration. The cuprizone diet model of MS causes oligodendrocyte death and myelin loss, and cuprizone withdrawal promotes oligodendrocyte regeneration and recovery. Thus, this model offers a paradigm to selectively study the neuroimmune response to demyelination and remyelination. Microglia are the primary resident immune cells of the brain, and although microglia activation is a robust response following cuprizone administration, the specific triggers of microglia activation are not well-defined. Moreover, the potential effects of cuprizone on microglia are unknown. In the current study, we characterized the temporal dynamics of microglial activation to cuprizone-induced demyelination. We administered mice with a cuprizone diet for 1, 2, or 4 weeks, or 4 weeks followed by one week on a regular chow (remyelination condition). Immunofluorescence analysis of the corpus callosum revealed a dramatic increase in microglia number and area by one week, that persisted throughout four weeks, followed by a partial reduction during remyelination. Three dimensional confocal imaging showed that activated microglia expressed the phagocytosis marker CD68 and colocalized with myelin, indicating microglial engulfment of myelin during cuprizone treatment. Next, we conducted real time qPCR in microglia-enriched samples from mice treated with cuprizone for one week. mRNA levels of *Tnf* and *Ifnb1*, genes involved in the proinflammatory cytokine response, were downregulated in the cuprizone group. This downregulation was correlated with upregulation of *Cd68* mRNA, indicating that the microglial switch to phagocytosis during cuprizone treatment is accompanied by a downregulation in inflammatory signaling. Surprisingly in the retina, which does not contain oligodendrocytes or myelin, microglia showed a suppressed phagocytic state, marked by fewer CD68 punctae. Our novel findings reveal that the microglial response during cuprizone treatment is paradoxical: a direct response to cuprizone, and an opposite and indirect response to the ongoing demyelination.

Abstract Name: A media-framing comparison of reproductive rights between Peru and Colombia

This study examines how newspapers based in Peru and Colombia based frame news articles about a woman's access to abortion through narrative devices. Therefore, the proposal analyzes tone, word choice, and sentence structure to uncover how print media constructs discourse regarding reproductive rights. This project contributes and extends to current academic discourse due to the language of the articles examining the use of tone and narrative techniques. This project engages with institutional policy because this research hinges how institutions help out with laws and legality of access to abortion. The data methods will decode and deconstruct narratives and synthesize insights for each of the articles. The data collection method will employ multi-scope framing analysis, examining textual, thematic, and linguistic devices to find patterns among the articles. This research project might conclude the articles from Colombia and Peru will contrast one another in regards of tone and language to a woman's access to abortion. Ultimately, the research project contributes to how language and framing in Latin American media influences public discourse and policy.

Abstract Name: Water memories and stewardship among residents of Wisconsin

Wisconsin is a water-rich state in the US, ranking fourth nationally in total water area. Water resources have long supported recreation, economic development, and a sense of place for many generations of residents and visitors alike. However, the water resources that have become a symbol of Wisconsin's wealth and identity now appear frequently in narratives that describe a state of concern. For example, there are growing incidents of surface and groundwater contamination, as well as rising levels of neurotoxins and other carcinogenic compounds in the state's water resources. Despite these threats and changes, questions regarding how people feel about water and how these connections continue to shape sense of place, identity, and attitudes have remained largely undocumented. Studies have demonstrated that people's affective connections to nature, including blue and green spaces, influence both well-being and environmental stewardship. Building on this foundation, this research seeks to examine how place-based storytelling generates feelings of interconnection that could foster empathy and stewardship for protecting water resources. This research will adapt the "watershed storytelling" methodology for exploring people's affective ties with blue spaces. The study will examine the following questions: How do residents describe the intrinsic value of water? How do residents experience and express their attachment to water? How do memories and sensory experiences of water differ across generations? How could storytelling foster empathy and a sense of care for water? The research will adopt both purposive and snowball sampling techniques for data collection. The researchers will collect and analyze qualitative data that explores sentiments relating to sense of place, sense of responsibility, perceptions of water quality change, emotions, and the willingness to act.

Abstract Name: Early Detection and Accurate Differentiation Between Epilepsy and Non-epileptic Mimics in Adolescents.

Early and accurate differentiation between epileptic seizures and non-epileptic mimics in adolescents is essential for preventing long-term cognitive, behavioral, and developmental complications. Because these conditions often appear similar, misdiagnosis remains common and delays appropriate treatment. This review brings together research across classification systems, genetics, molecular mechanisms, and emerging therapeutic approaches to highlight strategies that improve early detection and diagnostic precision in pediatric populations. The International League Against Epilepsy (ILAE) classification framework provides a clear structure for identifying childhood epilepsy syndromes and guides targeted genetic testing, including next-generation sequencing for disorders such as Dravet syndrome. Molecular studies further clarify the biology behind seizure activity. Research on adenosine signaling shows how genetic mutations disrupt neurochemical pathways and help explain overlaps between epilepsy and conditions such as autism spectrum disorder. Epidemiological work, including large cohort studies of drug-induced seizures, demonstrates how population-level data can uncover causal relationships while limiting bias. Genetic disorders such as tuberous sclerosis complex illustrate the value of proactive management. Early EEG monitoring paired with preventive treatment before seizures begin has been shown to delay seizure onset and reduce the risk of developing drug-resistant epilepsy. Recent studies on Glut1 deficiency syndrome also highlight the importance of distinguishing epileptic events from non-epileptic metabolic episodes. Improved metabolic testing and clearer diagnostic criteria have reduced misdiagnosis and opened the door for targeted therapies. This includes early-stage work on gene-based treatments aimed at restoring cellular energy balance and reducing seizure susceptibility, offering a potential future option for disorders rooted in metabolic dysfunction. Despite these advances, gaps remain in translating scientific insights into universally effective care. Future progress will require long-term clinical monitoring, broad genetic and biochemical profiling, and standardized intervention pathways. A multidisciplinary approach that integrates clinical, molecular, and population-based strategies will be essential to improving early diagnosis and personalized epilepsy management in adolescents.

Abstract Name: Plotting Parkinsons: Visualizing Motor and Non-Motor Symptoms on the MDS-UPDRS

Throughout the research and development of treatments for neurodegenerative disorder, like Parkinson's disease, large sets of clinical data are often being sifted through in a search for trends and improvements in patients. With a focus in Parkinson's disease and symptom progression, the International Parkinsons and Movement Disorder Society, MDS, developed a unified scale to evaluate the various aspects of Parkinson's disease. The MDS-sponsored revision of the United Parkinsons Diseases Rating Scale, the MDS-UPDRS, requires a physical exam and summarizes the characteristics of the motor and cognitive effects of daily living and motor complications. The summed totals support efficient communication between patients and doctors, but fail to accurately portray the distribution, range, and anatomical location of the various symptoms and disabilities. In depth analysis reveals a need for better paths for visualization of clinical data. To address this

issue, my team has developed multiple versions of a data figure modeled after the Vitruvian Man. In this model, the test results have been color coded and graphically distributed to show the progression of symptoms over a period of time. Furthermore, multiple trials and iterations of this model have been used in a larger clinical trial related to Deep Brain Stimulation and peripheral nerve tissue transplantation into the Substantia Nigra and Nucleus Basalis of Meynert. Ultimately, the goal is to identify innovative means to better visualize and analyze clinical data throughout neurodegenerative research.

Abstract Name: Colorimetric Dressing for Detection of Wound Infection

Burn injuries are highly susceptible to potential microbial invasion and subsequent infection due to the disruption of the protective skin layer and battlefield environment. Challenges such as early excision and skin grafting persist due to slow healing, infections, and burn progression which complicates the treatment process and potentially worsens the healing outcomes. The current standard of care relies first on clinical assessment of a patient's symptoms, and often antibiotics are used indiscriminately, even without confirmation of infection. This contributes to the development of antimicrobial-resistant strains of microorganisms. Infection detection involves culturing tissue samples, which is a time-consuming process. Patients managing their care at home often have reduced access to medical care and may delay seeking treatment, leaving the infection to spread rapidly. The solution to this is based on the detection of a molecule produced specifically by pathogenic bacteria. By incorporating a textile sensor window into a wound dressing, exudate absorbed by a dressing could change color if the wound is infected. The dressings consist of electrospun chitosan membranes, which are often used in regenerative applications like dressings. Chitosan is intrinsically anti-inflammatory and anti-microbial. We demonstrated feasibility by showing that small pieces of chitosan membranes with enzyme and substrate adsorbed turned from yellow to purple in the presence of *Staphylococcus aureus* and *Pseudomonas aeruginosa*, two common wound contaminants. This would provide a "window to the wound," allowing patients and clinicians to monitor the tissue status without having to remove the dressing, preventing further injury from dressing removal and reducing the risk of contamination from the environment. The research goals are to optimize fabrication, determine what concentrations of microbes can be detected, and determine how long it takes for color to develop. The next steps are to conduct preclinical evaluations to test the sensors at different concentrations and monitor response timings.

Abstract Name: The Tipping Point for Lunar Governance

As humanity prepares to return to the Moon, the greatest risk lies not in technical failure but in militarized competition: without clear governance, the race for lunar dominance could escalate into the first serious conflict in space. Traditionally, spacefaring nations have delayed rulemaking until disputes arise, but the stakes on the Moon are too high for reactive policy. Without agreed-upon guidelines, rival actors may clash over settlements, access to high-value locations, and rights to extract resources, threatening human life and

long-term stability. Using frontier case studies, ripeness theory, and international norm formation, this research addresses the critical gap in understanding when international governance becomes feasible and why timing will shape the success or failure of future cooperation. With both the U.S. and China planning sustained lunar operations, there becomes a narrow opportunity to establish governance before strategic infrastructure and resource use create irreversible first-mover advantages. The Outer Space Treaty provides a foundational framework but leaves critical gaps regarding surface use and resource extraction, exposing nations and private actors to potential disputes. Lack of wide-spread ratification of the Moon Agreement shows that overly broad or redistributive models lack political feasibility. However, narrower, targeted agreements such as the Return and Rescue Agreement and Liability Convention demonstrate that incremental, well-scoped rules can succeed. This paper explains why there must be galvanization around lunar governance now, before competition escalates into conflict. It argues the legal and political tipping point for governance will emerge in the late 2040s, when sustained operations, commercial extraction, and strategic interdependence make unregulated competition too costly to maintain. At that stage, frontier pressures will intersect with ripe conditions for negotiation, compelling actors toward international cooperation. The tipping point has not yet arrived, making early action essential. Only by establishing clear expectations now can the Moon develop through peaceful international collaboration.

Abstract Name: Computational Workflows Using Molecular Dynamics Simulations and Deep Learning

Proton transfer plays a critical role in many chemical and biological systems, but its ultrafast dynamics make the underlying phenomena difficult to capture experimentally. This raises a central question: how can computational workflows be constructed to accurately capture molecular behavior relevant to proton transport in supercooled water–glycerol environments, where hydrogen-bond disruption shapes diffusion pathways? To address this, the project focuses on the computational design, validation, and optimization of molecular dynamics (MD) simulations capable of generating high-resolution datasets suitable for downstream machine learning tasks. MD protocols are developed in GROMACS with systematic consideration of factors such as force-field selection, numerical stability at low temperatures, trajectory-sampling efficiency, and system-scaling strategies that preserve structural heterogeneity near the glass transition. Together, these simulation choices aim to capture the disruptive hydrogen-bond behavior observed in spectroscopy experiments and remain computationally tractable for large-scale data generation. Validated MD trajectories then function as structured datasets for neural network models that analyze spatial organization and time-dependent behavior in molecular configurations. Integrating simulation output with machine-learning pipelines provides a basis for identifying patterns and structural relationships that are challenging to resolve experimentally or through MD alone. The resulting workflow, spanning simulation design, data preprocessing, and neural modeling, demonstrates how computational methods can extend physical inquiry by transforming complex molecular motion into analyzable data. Building on this foundation, the project focuses on identifying structural features relevant to proton-associated dynamics and on improving machine-learning representations as additional simulation data becomes available. The immediate goal is to refine the integration of MD output with AI-assisted analysis in a way that remains reliable under low-temperature conditions. These developments will be presented in the context of current efforts to combine high-performance simulation with data-driven modeling in computational science.

Abstract Name: Economic Impact of the Great Lakes Aquarium

Located on the shores of Lake Superior in Duluth, Minnesota, the Great Lakes Aquarium is a key cultural and educational institution dedicated to showcasing the unique ecosystems of the Great Lakes region and beyond. The spending of nearly 200,000 out of town visitors each year drawn to the region by the Great Lakes Aquarium, as well as the aquarium's spending for its own operations, results in a substantial economic impact on the City of Duluth. This study seeks to quantify that impact using regional input-output modeling, mobile analytics data, and a visitor spending profile developed using prior data. Unlike traditional economic impact studies, this research incorporates mobile analytics data to validate visitor attendance, measure dwell time, and identify common visitor patterns, such as frequenting nearby leisure and dining establishments post-visit. Furthermore, a detailed visitor spending profile was developed using prior assumptions and existing data rather than costly and time-intensive intercept surveys. Results of this study indicate that the Great Lakes Aquarium contributes nearly \$43 million in output to the city in a typical year, along with supporting 387 jobs in the local economy.

Abstract Name: The Death of Free Art by the Hands of a Dancer

Although dance has been intertwined with culture for centuries, the question still stands for what makes one style more cultural than another, and how that has impacted society's view of dance. In this paper presentation, I dissect two examples observing the portrayal of characters and "ideals vs taboos." I will consider the complicated relationship between class and art that could lead to the death of free art. The history and representation of ballet envelop itself in suggestive content to present it as a higher art form void of culture, completely ignoring its roots ridden in western heritage. With that, an inherent separation has been created by Euro-American anthropologists placing a "we" vs "they" dynamic against cultures foreign to them. Along with the language, there is a discrepancy in defining cultural dance, where the connection arises in the primitive vs civilized archetypes. As we traverse beyond the anchors holding us to our past, many dance forms may be slowly becoming a distant memory to what our ancestors practiced. We must focus on educating the youth about the true meanings within the now hollowed walls of dance to prevent that from happening. Every dancer is as much a product of their past as they are a reflection of their times. Analyzing multiple sources, I argue my stance against the usage of the words "primitive" and "ethnic" in the dance world, along with the growing exclusivity of dance as the luxury of enjoyment that people can buy their way through an artificial art form.

Abstract Name: Mapping the Intersection of Clinical and Social Risk Factors for Kidney Disease: A Geospatial Analysis to Inform Community-Based Screening

Chronic kidney disease (CKD) disproportionately affects socially disadvantaged communities both globally and in the US. While chronic comorbidities including hypertension, diabetes, and obesity are known to lead to CKD, their intersection with social determinants of health (SDOH) like poverty, housing, transport, language, and the legacy of historic disinvestment, remains under-mapped for planning equitable prevention and screening. We integrated county-level estimates of cardiometabolic risk derived from CDC PLACES, social vulnerability derived from CDC/ATSDR SVI, and end-stage renal disease (ESRD) burden to visualize where clinical and social risks for chronic kidney disease (CKD) co-occur. We built a composite CKD risk score from age-adjusted hypertension, diabetes, and obesity, examined treatment coverage via BP-medication use, overlaid Social Vulnerability Index (SVI), and displayed ESRD burden. We then created two rule-based “hotspot” screens: (1) High CKD risk + high SVI + ESRD present and (2) Low CKD risk + high SVI (prevention targets). Maps revealed a broad high-risk corridor across the Southeast/Appalachia and Gulf Coast, distinct pockets of high hypertension with comparatively lower medication uptake, and clusters where high social vulnerability precedes clinical risk. These outputs nominate concrete counties for community screening and prevention initiatives and provide an adaptable framework for health-equity planning.

Abstract Name: Walk, Learn, Achieve the Study in Motion

Regular physical activity is widely recognized for its positive impact on health and performance, yet fewer than half of college students meet recommended activity levels. Since college represents a pivotal period for establishing lifelong habits, integrating sustainable movement strategies into academic environments may offer meaningful benefits for students’ long-term well-being. Current public health guidelines emphasize the importance of moderate to vigorous aerobic activity each week, but many students struggle to meet these targets due to academic demands, limited time, or lack of accessible equipment. Introducing familiar, low-barrier options such as compact treadmill desks in study spaces may help bridge this gap by allowing students to engage in light physical activity without interrupting their academic workflow. Walking requires minimal effort, reduces intimidation compared to more complex equipment, and can be seamlessly incorporated into study routines. The advantages of physical activity extend beyond physical health, positively influencing cognitive functioning, mental well-being, and academic performance. Movement has been shown to enhance executive functioning, attention, memory, and processing speed, both immediately and over longer periods. These cognitive benefits, paired with improved stress management and reduced depressive symptoms, suggest that even modest increases in activity can support students’ resilience and academic success. Promoting exercise in accessible formats may therefore contribute simultaneously to health and performance outcomes. This project expands on earlier research by increasing participant numbers and simplifying data collection to improve the validity and generalizability of findings. By examining how treadmill desk use affects academic outcomes, cognitive performance, and overall well-being, the study aims to highlight the value of incorporating movement into traditionally sedentary environments. Ultimately, this work seeks to demonstrate how shared treadmill desks can foster healthier study habits and contribute to a more supportive and productive campus community.

Abstract Name: IMPACT OF RESILIENCE AND PERCEIVED DISCRIMINATION ON BLOOD PRESSURE IN EMERGING BLACK ADULTS

BACKGROUND: Black adults experience the greatest prevalence of cardiovascular disease (CVD) risk of any racial or ethnic group in the United States. Racial discrimination is associated with elevated ambulatory blood pressure (ABP) and may exert a weathering effect that contributes to health disparities. While psychological stress resilience may mitigate CVD risk, limited research has examined its influence on perceived racial discrimination and ABP components, particularly nocturnal dipping and morning surge in young Black adults. **METHODS:** Black adults aged 18-29 (n=38, 47% female) completed 24-hour ABP monitoring, with readings taken every 20 minutes during waking hours and every 30 minutes during sleep. Nocturnal dipping was calculated as the ratio of average sleep to wake systolic and diastolic pressure. Morning surge was quantified using morning sleep trough, pre-awakening, and rising morning surge values for systolic and diastolic pressure. Participants completed a Brief Resilience Survey and a questionnaire assessing personal-level discrimination. Median splits categorized participants into low versus high discrimination and resilience groups. Independent t-tests assessed differences in discrimination groups and further stratified resilience groups. **RESULTS:** Among participants with low resilience, low personal-level discrimination resulted in significantly higher sleep trough morning diastolic surge (17.61 ± 4.43 vs. 8.13 ± 7.33 mmHg, $p=0.016$) and pre-awakening morning diastolic surge (11.50 ± 5.17 vs. 3.75 ± 4.68 mmHg, $p=0.013$), when compared to those with high personal-level discrimination. This finding was not observed in participants with high resilience. Only participants who exhibited low resilience and high personal-level discrimination were considered non-dippers ($<10\%$ systolic dipping percentage). **CONCLUSION:** Young Black adults reporting low resilience and high personal-level discrimination demonstrated attenuated morning surge alongside non-dipping nighttime patterns, which may represent an important early marker of elevated CVD risk. Future research should explore interventions aimed at enhancing resilience, including positive health behaviors such as regular exercise.

Abstract Name: Public Recognition of Female Track Athletes in the U.S.

Discrimination and inequality in sports towards women is a topic that is gradually gaining acknowledgment. Women are portrayed in the media differently than men and presented differently than their male counterparts. Until recently, women were rarely featured in athletic commercials, often seen in advertisements promoting food products or household items. Even when women are shown in sports media, they are frequently positioned alongside men, which leads to them being overshadowed. This misrepresentation projects harmful stereotypes and discredits the significant achievements of female athletes. This research explores the extent to which market representation and personal branding influence public recognition of female track athletes in the U.S. As a part of this research, I pose the following research questions: To what extent does market representation affect public recognition of female track and field athletes in the U.S.? To what extent does personal branding affect public recognition of female track and field athletes in the U.S.? By examining media portrayals, endorsement opportunities, and public perceptions, this study will contribute to a wider understanding of gender-based inequalities in sports. This research uses surveys and interviews as combined methods to examine the factors influencing public recognition of female track athletes. Surveys will gather quantifiable data from large, diverse populations to assess how market representation affects public recognition and identify broad trends. Interviews will provide in-depth qualitative insights into how personal branding strategies, social media presence, and individual athlete choice impact visibility and fan engagement. The findings may enhance women's agency in athletic spheres and encourage media organizations to adopt more equitable representation practices. This research expects to reveal significant disparities in media coverage and demonstrate that athletes with stronger personal branding will achieve greater public recognition despite their limited marketing representation.

Abstract Name: Voting Turnout Due to Felony Disenfranchisement

In the United States today, there are around 4.4 million Americans who are barred from voting due to felony convictions, due to various disenfranchisement laws and policies. My study will examine the impact of laws and policies that restrict ex-felons' voting rights on overall voter turnout rates in the United States from 2000-2004. My hypothesis is that laws restricting the voting rights of ex-felons affect overall voter turnout in a negative way compared to people without felony convictions. These restrictions negatively affect not only voter turnout but also the individuals who have had their rights stripped. By having policies set up for convicted felons, the inability to vote, you can see a drastic change in voter participation compared to those who have no criminal record. To explore this relationship, I used a quantitative research approach by using data from the voting census bureau and voter turnout data, then compared the population of those without the right to vote. I also analyzed the different policies and laws between various dates to see the difference in voter participation across America. I found that 5-27% of ex-felons participated in the voting process; however, after states enacted restoration processes, this percentage increased to 20-55%. My findings indicate that when ex-felons have access to automatic restoration, voter turnout increases in the political process. With this, if all states allowed automatic restoration for ex-felons, voting turnout would significantly increase.

Abstract Name: Beyond Game Day: A Case Study on Event Based Architecture in Campus Design

This research explores how Event-Based Architecture (EBA) principles can be applied to permanent and temporary architecture, campus planning, and event operations within a campus environment. It examines how EBA strategies, event accreditation, operations, overlay design, and adaptability, inform the integration of temporary structures with existing campus buildings and spaces to craft innovative and effective events. Through this framework, the study advances the understanding of environmental design strategies and the dynamic relationships between people, place, and space. EBA represents a “specialized discipline in which architects leverage expertise in venue and event design to influence both the planning and execution of live events as well as the conception of future facilities. The foundational EBA principles established by event design firms include event accreditation, which manages access and branding; overlay design, which adapts permanent architecture through temporary structures and signage; and operations, which ensures coordinated event execution” (Populous, 2020). Utilizing Louisiana State University as a case study, phase I employed a qualitative approach, exploring Southeastern Conference arenas and Olympic stadiums, observing live events, and interviewing stakeholders at EBA design firms, to apply the EBA principles to the permanent sports architecture campus masterplan. This research further applies adaptability as a key principle to reimagine how temporary architecture enhances event design. Adaptability provides the capacity to craft event programming to bring versatility to university sports architecture and its surrounding landscape through spatial, site, community and cultural analysis, generating economic, educational, and cultural value for all stakeholders that can be integrated in campus design.

Abstract Name: An Amperometric Sensor with Anti-Fouling Properties for Indicating Xylazine Adulterant in Beverages

Amperometric electrochemical sensing schemes, which are easily fabricated and can directly relate measured current with analyte concentrations, remain a promising strategy for the development of the portable, in situ detection of commonly employed adulterants. Xylazine (XYL) is a non-narcotic compound designed for veterinary use as a sedative known as Rompun®. XYL is increasingly being abused as a recreational drug, as an opioid adulterant and, because of its chemical properties, has found unfortunate prominence as a date rape drug spiked into beverages. In this study, a systematic exploration and development of fouling-resistant, amperometric XYL sensors is presented. The sensing strategy features layer-by-layer (LBL) modification of glassy carbon electrodes (GCEs) with carbon nanotubes (CNTs) for sensitivity and the engagement of cyclodextrin host-guest chemistry in conjunction with polyurethane (PU) semi-permeable membranes for selectivity. The optimization of different materials and parameters during development created a greater fundamental understanding of the interfacial electrochemistry, allowing for a more informed subsequent design of effective sensors exhibiting XYL selectivity, effective sensitivity, rapid response times (<20 s), and low estimated limits of detection (~ 1 ppm). Most importantly, the demonstrated XYL sensors are versatile and robust, easily fabricated from common materials, and can effectively detect XYL at >10 ppm in both common alcoholic and non-alcoholic beverages, requiring only minimal volume ($20\ \mu\text{L}$) of the spiked beverage for a standard addition analysis.

Abstract Name: The Impact of Natural Resource Dependency on Economic Growth of Central Asian Countries

This paper examines impact of natural resource dependence on the economic development in Central Asian countries: Kazakhstan, Kyrgyzstan, Uzbekistan, Turkmenistan, and Tajikistan. The economies of these countries are overly dependent on oil, gas, gold, and cotton, which creates both opportunities and threats. For example, oil rents in Kazakhstan exceeded 20% of GDP and 60% of exports, which shows its exposure to the impact of world oil prices. Kyrgyzstan is dependent on gold mining at the Kumtor mine, hydropower, and remittances, and GDP growth increased from -7.2% in 2020 to +9.0% in 2022. Turkmenistan, where gas exports account for the majority of government revenues, remains vulnerable due to weak diversification. Uzbekistan, a major exporter of cotton and natural gas, has recently embarked on reforms that have allowed for growth of more than 5% in recent years. Tajikistan, which has fewer resources, depends on remittances, which account for more than 30% of GDP. The paper concludes that weak institutions like corruption, excessive government control, and lack of transparency limit the benefits of resource wealth. A comparison with Norway shows that dependence on resources does not automatically lead to a "resource curse." Norway directs oil revenues to a sovereign wealth fund, has an accountable government and a low level of corruption, which turns wealth in natural resources into stability. This shows that the real difference lies in the quality of institutions. The conclusion is that Central Asian countries should strengthen their institutions if they want to transition from resource dependence to economic growth.

Abstract Name: Evaluating the effect of bmal1 knockout on rev-erb α expression in activin induced *Xenopus laevis* animal cap ectoderm.

Circadian rhythm is a phenomenon, such as sleep-wake, that oscillates over a 24 hour period. A molecular timekeeper is present in virtually all adult cells which involves a transcriptional/translational feedback loop (TTFL). Two components of the TTFL are Bmal1 and Rev-erb α . In the model organism *Xenopus laevis*, pluripotent animal caps (ACs) can be directed to become any cell type. This allows us to study the roles of clock-controlled genes during specification of cell fate. We hypothesize that Bmal1 and Rev-erb α regulate a shift in metabolism necessary for mesoderm specification. My experiment involves knocking out bmal1 in one cell embryos using CRISPR-Cas9, isolating and inducing ACs to form dorsal mesoderm (50ng/ml activin), and evaluating the effects on rev-erb α expression using qPCR. First, we isolated RNA from 12-24 hour old embryos, reverse-transcribed RNA into cDNA, and confirmed rev-erb α efficiency by passing a standard curve. Next, we compared bmal1 and rev-erb α expression in animal caps 0, 3, and 6 hours after activin induction. The next step is to analyze rev-erb α expression after bmal1 knockout. We expect that bmal1 knockout will decrease rev-erb α expression. The significance of this experiment is that we already know that Bmal1 transcribes rev-erb α in adults, but do not know if this relationship occurs during mesoderm specification in embryos.

Abstract Name: Comparative Analysis of Monotonically Enforced Univariate Binning Strategies in Classification Using Logistic Regression

Logistic regression, a workhorse for applications like credit scoring models, fundamentally assumes a linear relationship between continuous predictors and log-odds. This assumption often fails in practice, as risk patterns are typically non-linear. Discretization (binning) is a critical preprocessing step that allows logistic regression to capture these complex trends, significantly improving model performance. Yet, "the" optimal binning strategy is not well-established. This study addresses this gap by comparing ten monotonically enforced univariate binning strategies to evaluate their impact on logistic regression model performance and stability in risk assessment. Ten binning algorithms, including Equal Frequency, Decision Tree, ChiMerge, Isotonic Regression, and several hybrid methods, were evaluated. Each was used to discretize predictor variables for a logistic regression model. Performance was assessed using bootstrapped 95% confidence intervals derived from 1000 replicates for the Area Under the Receiver Operating Characteristic Curve (AUROC) and the Kolmogorov-Smirnov (KS) statistic. All strategies produced high-performing models, with AUROC values ranging from 0.8745 to 0.8850. The hybrid EqualFreqChi method achieved the highest mean AUROC (0.8850, CI: 0.8809-0.8887), with ChiMerge (0.8842, CI: 0.8793-0.8889), and DecisionTree (0.8832, CI: 0.8786-0.8876), also performing well. For class separation, DecisionTree (KS: 0.6136, CI: 0.6022-0.6248), and IsotonicRegression (KS: 0.6135, CI: 0.6013-0.6246), were the top performers, while the baseline Equal Frequency method was consistently among the lowest. Although performance differences were marginal in this particular use case, supervised methods like ChiMerge and Decision Tree-based binning offer an advantage over simpler techniques. The strong performance of the hybrid EqualFreqChi method also highlights the value of combining strategies. Since predictive power is comparable across the top methods, the optimal approach depends on the analytical goal. For instance, goals may include computational efficiency, where a less intensive method such as EqualFreqChi could be favored over a more complex one, without a significant trade-off in performance.

Abstract Name: Remembering Muhammad Ali: How ESPN Reports Following Ali's Death Have Shaped His Legacy

Muhammad Ali is widely praised as one of the greatest boxers of all times, but he fought in more places than the boxing ring. He advocated for Americans' most basic freedoms and used the principles of his Muslim faith to do so. Ali's membership in the Nation of Islam in the 1960s and 1970s empowered him to become an activist in the Black freedom struggle. Historians have investigated the intersections of Ali's racial and religious identities in relation to his social justice activism, offering compelling evidence that Ali's decision to

join the Nation of Islam in 1964 directly inspired him to act as a leader in the civil rights movement. My research explores the extent to which popular, contemporary media outlets, specifically ESPN, connect Ali's religion to his role in the rights revolution of the 1960s. Based upon my examination of ESPN articles following Ali's death in 2016, my project argues that the journalists continually failed to correlate Ali's membership in the Nation of Islam to his role as a civil rights activist. The erasure of Ali's Muslim identity from collective memory and his legacy is part of a greater challenge America continues to face—accepting, celebrating, and remembering marginalized identities. By understanding the complexity of Ali's intersecting identities, we can model the resistance and resilience necessary for meaningful social change.

Abstract Name: Biological Pathways and Sensory Meaning in Autism: A Cross-Level Synthesis

This medical humanities project examines how autism is represented across scientific, clinical, and lived-experience perspectives, focusing on sensory and developmental models. Both social and biological research confirm that autism cannot be reduced to a single concept. Autistic people describe their experiences in terms of perception, sensory intensity, and adaptive regulation, rather than deficits as described in diagnostic manuals. Biological models emphasize mechanisms like sensory processing, neural circuits, and genetic pathways. Social models emphasize development, interaction, and environment. This project compares, integrates, and synthesizes how diverse fields and actors – especially autistic people themselves – define and describe a key autistic trait: neurodivergent sensory perception. It begins with a scoping review of current literature, including biological and social models and theories of autism. The literature review examines animal behavior paradigms used to operationalize autistic sensory perception, such as valproic acid rat models and FMR1 and Shank3 knockout mice. This review also analyzes social science theories of autism and studies of autistic people's perspectives. Expected results are that biological and animal models often describe certain behaviors as markers of autism or dysfunction, confirming an accurate animal model, whereas autistic people often attribute similar behaviors as forms of sensory regulation and adaptation. Biological findings prioritize important measurable outputs. Lived perspectives emphasize context, function, and internal experience. The overlap of these findings can suggest that autism cannot be defined by one single explanation. It will highlight where and how animal models of autism fall short of being useful for understanding lived experience, and if and how published animal model research considers lived experience perspectives. This cross-level synthesis offers guidance for improving the design of behavioral assays, interpreting animal findings, and developing clinical approaches that align more closely with autistic perspectives and take a non-deficit approach.

Abstract Name: Will AI Replace Civil Engineers? An Undergraduate Investigation of Emerging Roles, Applications, and Expert Perspectives

My research began with a question that's increasingly relevant across engineering fields: Will AI replace civil

engineers, and how is AI currently being used in the profession? To explore this topic, I conducted a multimethod study that included a thematic review of 31 peer-reviewed papers and a survey of six academic and industry professionals with 2.5 to 25 years of experience in geotechnical, structural, and water resources engineering. Analyzing the papers revealed three major themes shaping current AI applications: AI-driven inspection of data acquired using drones and multimodal sensors for faster and safer bridge and road inspections, including automated defect diagnosis through computer vision; emerging machine learning models for predicting defect progression; and AI-supported maintenance planning using reinforcement learning and decision frameworks. The survey results reinforced these findings, with professionals reporting the use of AI for multi-domain information exploration, reducing research time, and presenting results in flexible formats. They emphasized challenges such as information bottlenecks, the need for complete datasets, and had concerns about data quality and AI's interpretability. Respondents also noted persistent, non-technical challenges in civil engineering that AI cannot solve. An example like managing expectations across stakeholders highlights the critical importance of human judgment and communication. My preliminary findings show that while AI can automate repetitive or hazardous tasks and enhance analytical workflows, experts consistently view it as a tool that augments rather than replaces civil engineers. I am now working with a faculty mentor to formally collect additional data and refine my thematic framework on a larger scale. Through this project, I've come to understand AI as a powerful collaborator that, when used responsibly with human expertise, can strengthen sustainability, resilience, and innovation across the built environment.

Abstract Name: Obstructive Sleep Apnea and Panic Disorder: A Critical Review of the Bidirectional Comorbidity

Obstructive Sleep Apnea (OSA) has a population prevalence of 2-4%, and is a sleep disorder that includes repetitive interruptions in breathing during sleep. Symptoms include sudden awakening, increased sympathetic arousal, sleep fragmentation, and daytime sleepiness, and are connected to the future development of significant health disorders. Panic Disorder (PD) is an anxiety disorder that includes symptoms of intense fear, increased heart rate, elevated blood pressure, and decreased quality of life. 18% of panic attacks occur from a sleeping state, and so, the comorbidity of obstructive sleep apnea and panic disorder is extremely significant in effective clinical treatment of patients. Panic attacks and OSA events can also occur in similar sleep stages (non-REM) with shared symptoms of shortness of breath and sudden awakenings. This paper aims to examine the bidirectional relationship between obstructive sleep apnea and panic disorder in the population and analyze the current, yet limited, literature on the subject. Twelve empirical studies were selected for this review, using the keywords: Sleep apnea or obstructive sleep apnea or apnea; panic disorder or panic or nocturnal anxiety. The studies determined that individuals with both OSA and PD presented with increased respiratory irregularities, which worsened individuals' sleep quality, arousal levels, somatic symptoms, and anxiety. Future longitudinal studies should aim to increase sample sizes, as diagnostic and treatment technology is now allowing a deeper analysis of the comorbidities that these two conditions are associated with. Increased awareness of OSA-PD comorbidity is essential for timely and accurate diagnosis. Increased awareness in research and clinical practice of the bidirectional relationship between OSA and PD is essential to emphasize how both conditions exacerbate each other's symptoms through shared physiological, neurological, and psychological mechanisms. An integrated clinical approach that considers both sleep and mental health may offer significant improvements in patient outcomes and quality of life.

Abstract Name: Resistance Characterization of PCB Traces and Vias for Improved Reliability in Modern Electronics

Printed circuit boards (PCBs) form the foundation of nearly all modern electronic devices, and their electrical performance is strongly influenced by the quality and uniformity of the copper features built into the board. These include surface traces that carry signals and power, as well as copper-plated vias that connect internal layers. Although these structures appear simple, small variations introduced during fabrication can meaningfully affect current flow, signal quality, and system reliability. In this project, I measured the electrical resistance of PCB traces and vias using precise four-wire measurement. This method eliminates the influence of lead and contact resistance, allowing for highly accurate evaluation of the copper itself. I also used best measurement practices to minimize measurement variation. By fitting the trace data to geometric resistance models, I extracted the sheet resistance and the etch-back introduced during manufacturing. The results show that trace variation is small and predictable, indicating that the trace fabrication process is highly reproducible across the lot. In contrast, the measured via resistances were significantly higher than the predictions—often by 20 to 90 percent, far beyond the measurement uncertainty. This demonstrates that via variation is large and not captured by simple geometric models. The discrepancy suggests that via plating is a major source of electrical variability and may vary substantially from board to board, even within the same manufacturing lot. The results not only provide practical guidelines for evaluating interconnect resistance in PCBs but also offer a foundation for improved modeling of signal integrity, thermal management, and reliability in high-performance boards. Therefore, this study provides valuable insights that can contribute to enhancing the overall quality and reliability of various modern electronic devices.

Abstract Name: Quantifying The Coandă Effect: Measuring how Airfoil Curvature Influences Lift

This project examines how airfoil surface curvature impacts airflow attachment and lift generation through the Coandă effect. Five 3D-printed NACA airfoils with camber values ranging from 0% to 9% were tested in an industrial wind tunnel at velocities of 5–20 m/s. Pressure sensors placed along each surface recorded changes in pressure distribution and lift. Airfoils with moderate camber displayed stronger attachment and a measurable increase in lift coefficient compared to lower curvature profiles. Higher curvature designs showed early separation, leading to a rise in drag. Smaller scale smoke visualization validated these results by generating longer attached flow regions for optimally curved surfaces. These results provide quantitative evidence connecting curvature to Coandă-driven lift enhancement and give insight into efficient flow control strategies that are relevant to optimal airfoil and UAV design. Limitations include minor turbulence fluctuations, which will be addressed in future testing.

Abstract Name: Understanding the Everyday: Investigating ancient Maya society in the city of Dos Hombres through household archaeology

The perspective of micro-scale social analysis in the archaeology of the ancient Maya presents the opportunity for a critical, detailed understanding of ancient households as a means for uncovering more about the everyday lives of those who lived there. Numerous household investigations have been conducted in northwestern Belize, with important findings occurring at the site of Dos Hombres. This research contributes to these previous findings, investigating the social, economic, and ritual activities that link a courtyard, Courtyard A-4 located directly adjacent to the large plaza, to the larger polity of Dos Hombres. Previous research in the courtyard household group revealed architecture in the southern courtyard boundary and locations of likely refuse disposal. While previous research has been conducted within Courtyard A-4, the largest and easternmost structure in the courtyard had remained unexcavated. The excavation of this household structure was necessary to create a holistic picture of the people who lived in the courtyard and their relation to the larger Dos Hombres polity during the Terminal Classical (CE 700-900). This study presents the results of a 1x3 m unit excavated on the eastern side of Structure A-29 in context with the previous findings to create a comprehensive picture of everyday life at this household located adjacent to Dos Hombres. The research presented reveals much about the daily activity of the inhabitants, including ritual domestic activities at the site, indicating that those who lived here likely practiced ancestor veneration and may have held an important role within the Dos Hombres polity.

Abstract Name: Evaluation of CYP3A4 Induction from Kratom — HIV Antiretroviral Drug Interaction using Quantitative PCR

Kratom, *Mitragyna speciosa* Korth, a tropical tree native to Southeast Asia, gained popularity in the United States for its psychoactive properties and potential therapeutic benefits. However, the use of kratom with antiretroviral (ART) drugs for HIV treatment raises concerns about potential pharmacokinetic interactions. Kratom contains mitragynine, the major bioactive alkaloid, which can interfere with drug metabolism in hepatocytes. Hepatocytes are the chief functional cells of the liver and are responsible for completing metabolic functions and they deliver more clinically translational data in terms of measuring CYP enzyme activity. Previously, the experimental design was developed and control parameters were optimized. Hepatocytes were cultured using various media and overlays, allowing for the most reproducible hepatocyte environment in control parameters. As sandwich-culture hepatocytes are more physiologically relevant, we focused on determining the best overlay to use for our experiment. In this project, we will implement the optimized experimental design by using human hepatocytes in a sandwich culture as a model to assess whether kratom extract and mitragynine induce CYP3A4 expression and how they interact with commonly prescribed HIV ART drugs. For induction assessment, the hepatocytes were plated in the optimized sandwich

culture and kratom, HIV ART drug, or a combination of both was administered for a 48-hour treatment period. mRNA was extracted and isolated from the hepatocytes for qPCR analysis to determine the cycle quantification (Cq) of each treatment. Using the $\Delta\Delta C_t$ method, we analyzed the relative expression of CYP3A4 and determined statistical significance via one-way ANOVA. FDA guidelines indicate that an increase of 2 or greater in mRNA expression is defined as induction. First trial results revealed that high concentrations of kratom extract and mitragynine induce CYP3A4. In summary, we analyzed CYP3A4 induction effects between Kratom and HIV ART drugs in human primary hepatocyte cultures.

Abstract Name: Breaking the Sound Barrier: How Verbal Participation Shapes International Student Integration in the Carter School

International students play an integral role in U.S. higher education by strengthening campus diversity, developing intercultural learning opportunities, and boosting the national economy. While universities work to recruit international students, many of their programs rely on learning approaches that overlook the challenges faced by students from non-participatory educational institutions. This study investigates how international students' propensity for oral engagement influences their ability to integrate into participatory pedagogy, specifically within the Jimmy and Rosalynn Carter School for Peace and Conflict Resolution at George Mason University. Existing literature shows two contrasting perspectives: one that emphasizes oral participation when used as a metric for academic success leads to inequities, and the other that proposes oral engagement strengthens intercultural competencies and social integration, allowing for academic acculturation. A survey was administered to international Carter School students at all degree levels to collect information on their oral engagement abilities, prior educational experiences, and perceptions of how the pedagogy of the Carter School impacts integration. Preliminary findings suggest a linkage between international students' oral engagement and their integration, with certain themes playing a more significant role. Students' prior educational experiences, especially those with early exposure to authority-based teaching, had lower confidence in oral communication than those from a discussion-based background who had inherent familiarity with oral participation as a means of social integration. Participation choices were dependent on TESOL-based educational backgrounds' focus on content comprehension and personal development, which led to topic understanding and personal confidence being key factors for engagement. Students unanimously perceived the Carter School as a positive environment that allowed for language fluency, peer connection, and strengthened comprehension. This suggests that universities with large populations of international students will benefit from a participatory pedagogy, as it works to allow better integration into the school system, leading to a more connected student body.

Abstract Name: Drinking Water Quality and Accessibility in Zambia

Poetice is a non-profit organization based in Choma, Zambia. Poetice staff work closely with two communities within the city of Choma - Kabanana and Mwapona - where they are involved in interventions to improve drinking water quality and access. The Global Water Research Institute (GWRI) worked with Poetice to evaluate water access and quality across existing water sources, with a goal of identifying potential improvements brought about by boreholes Poetice recently installed. Poetice and GWRI designed and trained staff on household surveys, which gathered information about household demographics, water collection and usage, cost, health, economic factors, and security. We also collected 59 water samples from three different site-types - shallow wells, taps and boreholes. The samples were tested for metal and VOC contaminants, E. coli, and total coliforms. In Mwapona, forty-two percent of the sampled sites had E.coli present and eighty-eight percent had total coliforms present. Seventy-five percent of the sampled sites were free from detectable metal and VOC contaminants. These results equip Poetice to communicate effectively with community members about the safest water sources to use. This research was supported by the Global Water Research Institute, Sawyer Foundation, Schaap Endowed Fund for Undergraduate Research, and the Hope College Biology and Chemistry Departments.

Abstract Name: Robotic Autonomous Navigation with Critical Visual Inspection

Autonomous navigation with seamless data collection becomes essential for overcoming potential hazards in a critical rescue mission. This project creates and tests the limits of a robotic system that analyzes the surroundings of an object of interest in real-time by analyzing streamed video data. Various navigation and artificial intelligence (AI)-based image detection algorithms have been developed; however, there is a need to analyze the challenges and constraints that occur when combining them on a physical system. This project utilizes a Scout Mini rover equipped with a lidar and camera, making it capable of autonomous navigation and data collection. The rover navigates through a known generated map to a given destination, and if an object of interest is detected in real time, a data collection procedure will occur. This procedure involves capturing a frame of lidar data, saving coordinates, and streaming camera data wirelessly. The transferred data is processed on a server frame by frame through a convolutional neural network (CNN) to classify objects that the algorithm is trained to detect. To test the reliability of the CNN on the server to detect surrounding objects, streamed frames were saved and analyzed at different confidence thresholds such as 80%. Images captured from the robot are noisy due to a combination of the movement of the robot and specifications of the camera. Therefore, utilizing a pretrained general purpose model, Faster R-CNN, objects were only detected at low confidence thresholds and misclassified due to poor quality of captured images. In conclusion, to increase the accuracy of object detection on moving autonomous vehicles with low specification cameras, either a domain specific CNN needs to be trained, or an algorithm that uses AI based super-resolution or deblurring techniques should be explored to increase the accuracy of object detection.

Abstract Name: An Interactive, Scalable Platform for Automated Neuron Segmentation and Proofreading in Connectomics

Nanoscale connectomics, the mapping of neural wiring at the synapse-level resolution in volumetric electron microscopy (EM) data, has already delivered complete synaptic wiring diagrams of entire microcircuits and small nervous systems that have enabled direct tests of circuit organization and computation. As the connectomics pipeline becomes more efficient, it now promises to scale to whole-brain reconstruction in larger organisms. Currently, the rate-limiting steps are segmentation and human proofreading, so realizing the full potential of advances will require that solutions to these bottlenecks be made accessible and scalable across laboratories of all sizes. Recent advances in segmentation have enabled large-scale automated neuron reconstruction. However, state-of-the-art automated segmentation can be prohibitive for smaller labs and those without extensive computing resources. Moreover, these reconstructions still require extensive human proofreading to correct residual errors and ensure circuit-level accuracy. To address these challenges, we present an automated and interactive neuron segmentation platform using Napari that integrates segmentation foundation models with a structured data-management pipeline optimized for large-scale volumetric image data. At the core of the platform is a prompt-based, human-in-the-loop segmentation workflow that enables users to iteratively guide and refine automated reconstructions with real-time feedback. This tight integration of automated inference with user correction enables rapid validation and correction of segmentation errors, leveraging automated segmentation to reduce the proofreading bottleneck. The system is also designed for memory-efficient interaction with large volumetric datasets, enabling scalable rendering, editing, and validation of reconstructions of full EM volumes with sufficiently low latency for interactive use on modest GPU hardware, supporting parallel proofreading across users with basic compute resources. In our workflow, this approach has already reduced end-to-end segmentation and proofreading time from weeks to hours for individual neuronal reconstructions.

Abstract Name: The Effects of Psychological Predictors and Social Behaviors of Conspiracy Belief on Relationships.

Conspiracy theories have played a large part in political and social discourse, especially during the COVID-19 pandemic when anti-vaccine conspiracy theories were on the rise. Since then, an influx of stories of relationships and families being torn apart because of conspiracy belief has occurred, with extreme cases being reported on news stations around the world. Some of these cases have led to the non-compliance of safety guidelines and promotion of unsafe actions that put people in danger, leading to a large amount of research on the predictors of conspiracy belief and its effects. The results of this research have found conspiracy belief to emerge in certain psychological traits that express selfishness and manipulative behavior, as well as social norm perception and behaviors. Analyzing the cause of the relational strain within cases, a clear comparison to the predictors of conspiracy belief can be made, however, the connection between the predictors and effects of conspiracy belief remains unverified and a deep examination of what the personal reaction is to conspiracy belief is lacking. In this paper, I propose my research question, "How do the predictors of conspiracy belief and the influence of social norms and behavior affect interpersonal relationships?". Using this question, I plan on gathering participants through online means, and analyzing

their demographics, psychological traits as well as their social behavior and comparing it to their interaction with conspiracy believers. I anticipate similar results to methods borrowed from previous research, as well as a connection between traits identified to be predictors of conspiracy belief and behaviors within relationships affected by conspiracy belief. In doing this, I hope to provide insight into how people interact with conspiracy believers and hope future research will build upon my findings to potentially develop methods that reduce conspiracy belief and promote healthier relationships.

Abstract Name: From Isolation to Integration: Reimagining Connection in Disconnected Times.

Across the world, people are experiencing a growing sense of social and cultural disconnection - from community, culture, and even self. Yet dominant health systems continue to focus on individual treatment, often overlooking the collective, cultural, and spiritual roots of this crisis. My research explores (1) how dominant health frameworks overlook the relational and symbolic ways people heal, and (2) how creative, culturally grounded practices - such as art, storytelling, movement, and ceremony - can restore connection where clinical models fall short. Through a three-month internship with Te Oranganui, a Māori-led health organization in Aotearoa, I examined how Mātauranga Māori (traditional knowledge) is woven with Western frameworks to support holistic care. Using participant observation, semi-structured interviews, and participatory art-based reflection, and guided by decolonial and relational ethics, I explored how healing takes shape through relationships, place, and collective practice - rebuilding connection across spiritual, cultural, and communal dimensions of health. Findings suggest that healing from social and cultural disconnection is collective, relational, and deeply tied to place. Across wānanga (higher learning spaces), communal mirimiri (bodywork) sessions, and daily interactions, connection is restored through shared creativity, symbolic storytelling, and ritual practices that center relationship over diagnosis. When people engage with healing as a communal and symbolic process, it not only supports individual well-being but also strengthens the social and spiritual fabric that clinical models often overlook. This research offers insight into how culturally grounded, multi-method approaches can inform more relational models of care. Recognizing the spiritual, symbolic, and communal dimensions of healing can contribute to broader conversations about decolonizing health systems and reimagining care as a process of reconnection - between people, culture, and the natural world.

Abstract Name: No guts, no glory: Variation in invertebrate community composition and succession in eviscerated European starling (*Sturnus vulgaris*) carrion in southeastern Wisconsin

Carrion provides an immense, but ephemeral, opportunity for a variety of invertebrate taxa in a diverse microecosystem. Among the most well-researched characteristics of these microecosystems are community composition and temporal insect succession patterns, both of which are known to vary based on numerous environmental and cadaveric conditions; nevertheless, many potential causes of variation remain under-

researched. In this study, the impact of carrion evisceration on the invertebrate community composition and succession timeline in a new growth forest in southeastern Wisconsin was assessed using six juvenile European starling (*Sturnus vulgaris*) carcasses from August 19th to September 8th, 2025. Overall, community composition varied slightly between control and eviscerated *S. vulgaris* carcasses ($R = 0.1051$, $p < 0.05$), with a greater invertebrate diversity at control carcasses (control $H' = 2.13$, eviscerated $H' = 1.19$). Timelines of colonization, modeled using the duration of presence of Calliphorid (Diptera) larvae, showed that the eviscerated group had on average a later peak larval density (control $\mu = 4 \pm 0 \text{ days}$, eviscerated $\mu = 5.3 \pm 0.58 \text{ days}$) and a later disappearance of feeding larval masses (control $\mu = 8 \pm 2 \text{ days}$, eviscerated $\mu = 14 \pm 3.46 \text{ days}$). The earlier drop-off of Calliphorid larvae colonization in the control group coincides with an earlier start of active decay, and a final assessment of the carcasses found a greater degree of skeletonization in the control group, indicating that the decomposition process proceeded more rapidly in the control. This study suggests the presence of visceral organs in carrion has an impact on both the invertebrate community composition and succession timeline. These results present a novel factor for consideration in decomposition research.

Abstract Name: Plants and Pollinators on VCU'S Campus: A Diversity Assessment of an Urban Meadow and Lawn Site

The purpose of this study is to compare plant and pollinator diversity in a native urban meadow versus a traditional lawn on VCU's campus and to incorporate public input on these ecosystems. The Office of Sustainability at VCU seeks to increase campus biodiversity. This research will confirm the efficacy of their biodiverse planting initiatives and provide a robust framework for future meadow management and monitoring protocols. The newly planted Cumberland Wedge Meadow is the study site with a nearby traditional lawn area as the control. Four inventories were completed between late September and mid-October. Quadrats were used to identify and count vegetation to estimate species diversity. For pollinators, data was collected via 3-minute, fixed duration surveys within 2m by 6m transects, with all pollinators observed within the boundaries being identified and counted. Shannon diversity indices were calculated in R using species counts to assess the overall abundance and evenness of species within each site. Supplemental to quantitative data collection, a qualitative survey of the campus community was performed to elicit diverse input on planting strategies. The Shannon diversity index (H) values demonstrated a higher level of plant diversity in the meadow ($H=1.63$) relative to the lawn ($H=1.08$), signifying superior species richness and evenness in the meadow. Pollinator diversity followed a similar pattern, recording a high index of $H=1.87$ in the meadow and $H=0$ in the lawn. The VCU meadow, characterized by a higher abundance of native plants and greater plant diversity, supports a richer and more abundant pollinator community when compared to the adjacent lawn site. This independent study concludes that the implementation of more biodiverse native plantings on campus is an effective strategy for increasing pollinator populations. Furthermore, a qualitative study demonstrated community endorsement, with 96% of 29 VCU community respondents indicating strong support for planting initiatives.

Abstract Name: Lincoln's Folly, Cherokee Secession, a Diplomatic Failure and a Human Tragedy: The story of why John Ross and the Cherokee Nation sided with The South.

This paper examines the Cherokee Nation's secession during the American Civil War, framing it as both a diplomatic failure of the Lincoln administration and a human tragedy for the Cherokee people. It argues that internal class divisions, the influence of pro-slavery elites, and the structural corruption of the Indian Office created fertile ground for Confederate diplomacy, while Union mismanagement and neglect forfeited potential Native alliances. Particular attention is given to John Ross, whose pragmatic leadership was undermined by Confederate commissioner Albert Pike's exploitation of factional divides and the Union's withdrawal of military and financial support. Although large segments of the Cherokee population resisted secession, elite pressure and the absence of federal engagement pushed the nation toward the Confederacy. The study contends that this episode reveals the perils of disregarding peripheral actors and treating local elites as representative of entire communities, a lesson with enduring implications for diplomacy in regions marked by class inequality and contested sovereignty.

Abstract Name: Overcoming Barriers in Kinetic Analysis to Resolve Mechanisms of Nanoparticle Formation Using Video-Based Analyses

One central challenge in nanomaterial chemistry is understanding the transformation of molecular reagents into discrete solid nanoparticles (NPs); relevant steps require high spatial, temporal, and chemical resolution to interpret. Standard tools such as ultraviolet-visible extinction spectroscopy lack the resolution to track fast steps in NP formation. Ultrafast spectroscopies improve temporal resolution and resolution of molecular transformations but often miss the formation of the solid NPs and are typically inaccessible to non-experts. Computational approaches, such as population balance models (PBMs), simulate changes in NP concentration and size to inform NP nucleation and growth, but their accuracy depends on experimentally measured kinetics that are seldom available. Together, these challenges limit our ability to mechanistically explain NP formation and tune synthesis conditions for drug delivery, disease diagnostics, and renewable energy. In this project, I bridge this gap by developing a video-based analytical tool that estimates NP formation kinetics from real-time color changes to identify NP formation mechanisms. I applied this tool to probe how phosphine-ligand steric bulk about a gold center directs NP formation. I synthesized a series of three gold-phosphine complexes with increasing steric bulk and tracked color intensity as a measure of NP formation, observing slower particle formation for more sterically hindered ligands. Complementary analysis using transmission electron microscopy-generated NP size distributions does not follow classical expectations from the kinetic analysis, suggesting that a non-classical pathway—particle coalescence—may govern final particle size. To test this, I am developing a PBM that simulates NP formation under classical and non-classical conditions. Importantly, the video-based tool I developed can track reactions with temporal resolution limited only by the frame rate and analyze solutions with higher optical densities than traditional absorption spectroscopies, including opaque samples. Overall, this research addresses limitations in experimental resolution and computational parameterization, enabling new methods to establish mechanism-based control of nanomaterial properties.

Abstract Name: Discovering Antibiotic-Producing Bacteria in Local Soil Through Tiny Earth Research

With the rising global prevalence of antibiotic-resistant infections, the search for novel antimicrobial-producing bacteria has become a scientifically relevant pursuit. Tiny Earth is an international undergraduate research initiative to study soil microorganisms for antibiotic-producing compounds through accessible, authentic research experiences. Here we present two soil samples collected from the Zachary Taylor Trail creek bed in Arlington, Virginia (38.90512° N, 77.12245° W), an environmentally nutrient-rich and microbiome-diverse location. To achieve isolated single colonies, a series of dilutions was performed on each sample, and through these dilutions, colonies with unique morphologies were successfully isolated and purified on a nutrient agar plate to reduce contaminants and ensure a diverse representation of isolates for study. Purified isolates underwent screening for antimicrobial activity against the Tiny Earth ESKAPE analog pathogens: *Escherichia coli*, *Staphylococcus epidermidis*, *Enterobacter aerogenes*, *Mycobacterium smegmatis*, *Enterococcus raffinosus*, and *Acinetobacter baylyi*. Isolate #2 didn't produce any zones of inhibition, while isolate #1 produced zones of inhibition. Isolate #1 produced zones of inhibition against *E. aerogenes*, *M. smegmatis*, *E. coli*, and *S. epidermidis* with the potential for broad spectrum activity between Gram positive and Gram negative pathogens; it is even more compelling that this isolated was identified as a Gram negative after Gram staining, correlating to common soil genera *Pseudomonas* which are known for producing a multitude of secondary metabolites with biological efforts against other competing microorganisms. Future directions include polymerase chain reaction and gel electrophoresis to support genetic inquiry and accurate taxonomic identification, as well as to determine the genetic potential for antimicrobial production. These results confirm the Tiny Earth initiative as naturally occurring, non-pathogenic soil bacteria can be scientifically validated as potential sources of viable antimicrobial components to fight antibiotic-resistant pathogens.

Abstract Name: Method Development for Inductively Coupled Plasma-Mass Spectrometry Quantification of Cadmium and Trace Metals in Mouse Diets

Cadmium (Cd) is a toxic heavy metal and environmental contaminant widely found in industrial emissions, tobacco smoke, and contaminated food and water. Cd primarily accumulates in the kidneys and liver, where its long biological half-life contributes to prolonged systemic toxicity. It is classified as an independent risk factor for cardiovascular disease (CVD) by the American Heart Association, with chronic exposure linked to

hypertension, atherosclerosis, and cardiac dysfunction. Despite its established cardiovascular risk, the mechanisms by which Cd exposure alters cardiovascular function remain poorly understood. In this study, we aim to develop a mouse model of Cd exposure to investigate its associated CVD effects. Mice are provided with diets containing 10, 50, and 100 parts per million (ppm) of cadmium chloride (CdCl₂) to represent low, moderate, and high exposure levels, respectively. We will quantify Cd levels in the custom-made diets and organs using inductively coupled plasma mass spectrometry (ICP-MS). Samples from the Cd-supplemented diet pellets, blood, urine, heart, kidneys, bones, and other tissues are digested in nitric acid to prepare solutions compatible with ICP-MS analysis. The objective is to refine digestion parameters by finding the optimal nitric acid concentration, volume, and incubation period needed to ensure complete sample dissolution. Once the samples are fully digested, we will quantify Cd levels using ICP-MS. These results will help assess how different dietary Cd levels and exposure durations influence its accumulation in various tissues, providing insight into metal toxicity and potential cardiovascular effects.

Abstract Name: Investigating the Use of Clinical Preventative Measures on the Impact of Myopia Progression in Children and Adolescents

The prevalence of myopia, or nearsightedness, has surged since the pandemic in 2020, especially within younger children and adolescents, raising concern amongst ophthalmologists and public health specialists. This poster discusses environmental and behavioral contributors to myopic progression, focusing on increased screen time, reduced outdoor exposure, and the structural development of the eye. The findings in clinical studies used in this poster consider how demographic and genetic factors influence an individual's susceptibility to myopia. This poster also explains certain preventative measures such as the use of contact lenses to slow axial elongation, as well as multi-colored light therapies (blue, red, blue-violet lights) and how they can boost natural production of hormones within the eye to prevent myopia. Furthermore, studies conducted to test topical low-dose atropine treatments are evaluated to understand how they can stop the progression of the eye condition in children, when they are most susceptible to developing myopia. This poster also examines the regulatory challenges around topical atropine, which is a treatment used around the world, but is not FDA approved, preventing it from being used in clinical settings. By integrating research and clinical data, this review will offer a comprehensive understanding of myopia and its multifactorial origins to understand the paths of action for early intervention within all populations, focusing on pediatric communities. Moreover, this poster uses its findings to offer solutions and practices that can be implemented in urban settings (schools, offices, ect.) to catch early onset of myopia and prevent it from developing. Ultimately, it advocates for a more proactive effort against the development of myopia and urges professionals to advance the treatments for the wide-spreading eye condition.

Abstract Name: Effectiveness of Mindfulness-Based Stress Reduction (MBSR) for Undergraduate Students: A Systematic Literature Review on Stress Levels

MBSR (Mindfulness-Based Stress Reduction) therapy is a psychological intervention that seeks to decrease stress levels by focusing on an individual's concentration in the moment and openness to new experiences (Pan, 2024). In more recent times, prevalent psychological signs of distress seen in university students include anxiety, mental stress, and emotional distress (Pan, 2024). The purpose of this research is to investigate the effects of MBSR on stress levels of varying undergraduate student populations. University students have the autonomy to decrease stress levels and enhance self-care practices by regulating their thoughts, emotions and behaviors through practices such as meditation. The study design of this investigation includes finding MBSR relevant academic articles utilizing the Web of Science database and conducting a systematic literature review to ensure an objective lens. The data collection process for finding relevant articles consists of peer-reviewed academic articles using randomized controlled trials focusing on MBSR and its effects on stress levels in university students. Initially, key conclusions were drawn from the data. Following creating concept maps to visualize patterns in the data, broader themes were identified. These themes were then synthesized to investigate the research question. A key finding from the literature review has shown that university students that participated in MBSR training saw significantly reduced depression, stress, and anxiety levels compared to a control group. MBSR training can promote positive mental health and an inclusive environment. An implication to MBSR in a college setting would be to include it in stress management and mental health services to improve student well-being. A limitation to this implication would be that this practice may not be effective for everyone. In future studies, MBSR should be studied comparative to other stress-reduction strategies to test its complete effectiveness.

Abstract Name: Characterizing the Cell-Autonomous Role of CHCHD2 in Neural Stem Cell Fate Decisions during Adult Hippocampal Neurogenesis

Adult Hippocampal Neurogenesis (AHN) is an exciting process wherein an endogenous pool of neural stem cells (NSCs) in the hippocampus makes fate decisions to become adult-born neurons. NSCs primarily rely on glycolysis and fatty acid oxidation. As they shift into active proliferation or differentiation, they increasingly depend on mitochondrial oxidative phosphorylation (OXPHOS). Coiled-coil-helix-coiled-coil-helix domain containing 2 (CHCHD2), a mitochondrial gene that enhances mitochondrial dynamics and OXPHOS, has emerged as a critical mediator of molecular pathways regulating AHN. It is highly expressed in NSCs, and global CHCHD2 knockout impairs AHN. Elucidating CHCHD2's necessity in AHN is key to advancing our understanding of NSC biology and identifying strategies to enhance neurogenesis. A tamoxifen-inducible triple-transgenic mouse model (Ascl1CreERT2:CHCHD2^{fl/fl}:R26^{tdTomato}) was used to selectively excise CHCHD2 in active NSCs and trace their neurogenic lineage progression. Coronal dentate gyrus sections were collected at neurogenic time points (7-, 14-, and 32-days post-injection) for immunohistochemistry and confocal imaging. Neurogenic lineage progression was assessed using cell-type-specific markers, while cellular morphology was quantified via radial process length, dendritic complexity, and dendritic spine density. While proliferation and immature neuron populations increased, the marked NSC and progenitor pools remained unchanged. CHCHD2 excision increased NSC activity but biased NSCs toward premature neuronal differentiation into immature neurons. CHCHD2-deficient cells exhibited shorter radial processes, reduced dendritic branching, and decreased spine density, indicating impaired morphological maturation as well. These observations indicate that CHCHD2 is necessary to maintain balanced NSC self-renewal and differentiation along with maintaining proper NSC neurogenic lineage progression.

Abstract Name: Synthesis and Binding Study of p-t-butylcalix[4]arene Hosts Featuring Pyridine or Quinoline Motifs on the Lower Rim

Molecular baskets are a group of synthetic host molecules designed to govern the inclusion of desired guest molecules. We present the synthesis and binding studies of p-t-butylcalix[4]arene hosts bearing pyridine motifs on the lower rim. The two pyridine-containing motifs are nicotinoyl groups or 7-quinoline carboxylate groups. The synthetic pathway involves converting a carboxylic acid into an acid chloride using thionyl chloride. The resulting acid chlorides are used to di-functionalize two of the phenol groups in p-t-butylcalix[4]arene in an acetonitrile solution. The hosts are purified by column chromatography and characterized via ¹H NMR and MS. The host-guest binding studies are carried out by ¹H NMR and UV-Vis titrations with silver(I) triflate. The binding constants are obtained based on non-linear curve fitting of selected chemical shifts.

Abstract Name: The Effects of UV Degradation on the Dynamic Properties of Indigenous Woods for Blast Hazard Mitigation

As global interest in sustainable construction grows, wood has emerged as a promising renewable material due to its high strength-to-weight ratio, cost-effectiveness, and availability across diverse regions. While prior research highlights wood's efficiency in energy absorption and shock dissipation, its long-term performance after environmental exposure—particularly under extreme dynamic loading—remains insufficiently understood. This study addresses a critical knowledge gap by examining the extent to which ultraviolet (UV) induced surface degradation affects both flexural strength and high-strain-rate energy absorption capacity across multiple wood species and grain orientations. The focus of this project is to investigate how ultraviolet degradation influences the dynamic mechanical behavior of indigenous wood species used in blast-mitigation and protective structural systems. The research employs a three-phase experimental approach. In the first phase, hardwood and softwood specimens with controlled grain orientations undergo accelerated UV exposure designed to replicate months or years of environmental aging. In the second phase, quasi-static four-point bending tests are conducted to quantify reductions in flexural strength and stiffness, establishing a baseline for interpreting dynamic behavior. In the third phase, dynamic impact experiments using a two-stage light gas gun to evaluate how UV exposure alters the materials' ability to absorb energy and deform under blast conditions. Data from these phases will be compared across species, grain orientations, and exposure durations to identify trends in mechanical degradation and their structural implications. It is anticipated that UV exposure will significantly reduce flexural strength, diminish energy-absorption capacity, and potentially alter deformation modes during high strain-rate loading. These results will be discussed in the broader context of designing sustainable, resilient, and locally sourced protective structures. By developing predictive relationships between environmental aging and dynamic performance, this project contributes new knowledge to the study of natural materials in extreme conditions and supports the advancement of safer and more sustainable blast-resistant infrastructure.

Abstract Name: Impact of Low Resource Availability during Early Post-Natal Development on Adolescent Play Behavior in Rats

Maternal postpartum depression is a prevalent health concern that affects a mother's long-term health as well as the maternal-infant bond, a foundation for infant social development. Low socioeconomic status (SES) generates additional stressors that can have a significant negative impact on new mothers and their infants. Studies show women who present with four SES risk factors have an eleven times higher risk of experiencing postpartum depression than their counterparts. Furthermore, low SES during infancy has been linked to effects later in development for children and adolescents, including observations of emotional dysregulation and increased rates of depression, anxiety, and aggression. Individual contributions of the early postnatal environment versus other stressors in childhood and early adolescence are difficult to discern in humans because they are rarely limited to discrete developmental phases. Rodent studies can provide opportunities for controlled assessment of models of SES, typically manipulation of available resources, limited to specific developmental phases. Here, we tested the hypothesis that exposure to limited bedding and nesting (LBN), a model of low SES, during early development, will alter play behavior during adolescence. On postnatal day (PND) 2, Long-Evans dams and their pups were assigned to LBN (n= 74 male, 78 female) or standard housing (n= 80 male, 82 female). On PND 21, all offspring were weaned from their mothers and pair-housed by sex in standard housing conditions. Play behavior was recorded on PND 36 and analyzed with EthoVision XT 18. Outcome measures include latency to play, interaction speed, and play duration. Two-way ANOVAs will be used to determine whether the impact of LBN on play behavior differs by sex. Investigating the impact of early life stressors on play behavior will build an understanding of postnatal stress exposure on later social behavior development. This will allow for further insight into the development of potential intervention strategies.

Abstract Name: Kill the Lights: Quantifying Dynamic Bond Behavior through Manipulating Light Sensitive Molecules

A human embryo develops in the womb through stem cell evolution. Controlling this development was recently discovered to be possible through manipulating the stem cell environment. The environment (typically tissue) controls cell growth based on its stiffness. The exact process, however, has to be explored

through experimental cell studies. Hydrogels, or polymers swollen in water, mimic the stem cell environment well. Manipulating hydrogels to imitate the dynamic tissue environment is possible through a stimulus such as concentration or temperature. Light is an ideal stimulus since the application is reversible, precise, and tissue-friendly. Whereas other stimuli can kill stem cells, light does not. Hydrogel stiffness can be altered with light through the incorporation of photoactive molecules and reversible bonds into the hydrogel. Analyzing the success of this incorporation requires observing the material change properties with light irradiation. My goal is to quantify how light can change the behavior of the photoactive molecules in dynamic bonds. I am analyzing how changing substituents on the photoactive molecules change the general behavior of the dynamic bonds. Harnessing specific characterization techniques to analyze these properties will help us gain a better understanding of how light affects dynamic bonds. My analyses will be used to understand how these photoactive molecules will behave in a hydrogel. Conducting cell studies atop these hydrogels will deepen our understanding of the processes behind organ formation, which could benefit the biomedical field by improving the creation of prosthetic organs like ears and noses.

Abstract Name: Investigating Microbial Signatures of Mosquito Oviposition Sites

Mosquito-borne diseases remain a pressing global health concern, killing nearly 1 million people every year, and understanding mosquito oviposition behavior may reveal new avenues for vector control. Female *Aedes aegypti* mosquitoes lay their eggs near water, and previous studies have shown that they often exhibit aggregation behavior during this process, which is the non-random distribution of *Ae. aegypti* females at one oviposition site over another. We hypothesize that mosquito aggregation at oviposition sites alters the microbial composition of the water, producing bacterial communities or signatures that are more favorable for larval development. To test this, we designed an aggregation assay in which cages containing 35 gravid mosquitoes were presented with two equal oviposition sites. Acrylic traps around each site restricted movement once a choice was made. After 24 hours, the number of mosquitoes at each site was recorded, and water samples were collected. These samples were filtered, followed by DNA extraction from the retained material. The bacterial communities will be profiled using 16S rRNA sequencing and compared across aggregated sites, non-aggregated sites, and controls. We expect that aggregated oviposition sites will have greater bacterial abundance or distinct bacterial signatures relative to non-aggregated sites. Such differences could suggest that mosquito site choice is influenced by microbial cues, creating environments more favorable for larval survival. Ultimately, this work could provide new insights into the ecological interactions driving mosquito oviposition behavior and identify potential microbial targets for novel mosquito population control strategies.

Abstract Name: Development of an in vitro model of wound healing in human embryonic kidney (HEK 293) cell cultures to test the impact of crude keratin on healing

Crude keratin is a processed form of keratin that contains alpha and gamma keratins. It is extracted from animal byproducts including feathers and hair. Current research provides evidence that keratin promotes wound healing by stimulating cellular migration and it can act as structural scaffolding for new cells. To identify the possible effectiveness of crude keratin to accelerate healing in a simulated wound environment, human embryonic kidney cells (HEK) 293 cells were subjected to different stressors. Previously described methods were used to simulate and measure wound healing of HEK293 cells: a scratch assay, heat shock, and transfection. The scratch assay was performed by dragging a pipette tip along the middle of the well to detach cells and create an in vitro wound. The plates were viewed with an Evos Fluorescence Microscope to measure the migration capabilities of the HEK 293 cells with and without crude keratin. Heat shock was performed to simulate stress to create a more accurate model of wound healing. HEK 293 cells that were subject to scratch assays were placed in a 45 °C water bath for predetermined times. The scratch assays showed signs of improved healing with crude keratin during the first 90 minutes. The healing factor returned to baseline after 90 minutes depicted by cell migration into the wound site. Heat shock experiments displayed no cell damage and had the highest range of variance of cell growth at the 60-minute mark. Future experiments will conduct interval checks on cell migration more frequently and for longer periods of time to obtain a more accurate picture of wound healing patterns.

Abstract Name: What America Runs On: A Regression Analysis of the Economic Factors Influencing Coffee Prices in the United States

This study investigates the extent to which various economic factors have influenced the price of coffee in the United States between 2018 to 2024. Since the onset of COVID-19, there have been substantial price escalations in coffee, with pre-pandemic prices averaging \$1.41 and post-pandemic prices averaging \$2.32. While there are many ongoing discussions in economics about the factors influencing the price of commodities, more research is needed to bridge the gap in the existing literature on factors influencing coffee prices, as most articles are either a decade old or pre-pandemic and do not include a comprehensive analysis of influential variables. A multivariable linear regression was conducted for this research to establish a relationship between the dependent variable, coffee prices in America, and numerous independent variables, inflation, the exchange rate between USD and COP, job openings, trucking costs, the federal funds and unemployment rates, and oil prices. The analysis revealed that the Federal Funds Rate, inflation, oil prices, and the exchange rate between the U.S. dollar (USD) and the Colombian peso (COP) all had statistically significant effects on coffee prices. While each variable exhibited a positive relationship with coffee prices, the Federal Funds Rate exerted the most substantial influence, suggesting that monetary policy changes play a critical role in shaping global coffee market dynamics. The importance of this result lies in its contribution to the information policymakers can utilize for policies they can put in place to support or aid the coffee industry, as well as other importing farm industries.

Abstract Name: Stigma and Placement Instability in U.S. Child Welfare Systems

Child welfare agencies across the United States rely on standardized behavioral and mental-health forms recorded in systems such as CATS and TRAILS to communicate information about foster youth when matching them to potential placements. These forms contain “checked boxes” indicating behavioral concerns or mental-health challenges, but they provide no narrative context. Once entered, these indicators cannot be removed, even if the behavior occurred years earlier or no longer reflects the youth’s current functioning. Because foster parents often make placement decisions based solely on the number or type of boxes checked, this documentation structure may unintentionally promote stigma and contribute to placement instability. I ask how do checkbox-based heuristics shape perceptions of foster youth, and how might added context reduce stigma and improve placement outcomes? Prior research documents stigma directed toward foster youth, little is known about how data systems and referral processes perpetuate these perceptions. I aim to fill that gap by examining how the lack of contextual information and the permanence of outdated history affects decision-making. Using a mixed-methods design, this study includes qualitative structured interviews with former foster youth and child welfare professionals to explore lived experiences with the checkbox system and its consequences. Additionally, a quantitative Qualtrics experiment in which participants review simulated placement forms and indicate whether they would be willing to live with the youth described. Participants will first view forms with varying numbers of checked boxes, followed by a second version that includes additional details or removes outdated history. I hypothesize that this added clarity will significantly reduce stigma, increase willingness to accept youth, and foster more developmentally informed decisions. Expected findings will demonstrate how seemingly neutral documentation tools can reproduce inequities, shape placement opportunities, and contribute to “hard-to-place” designations. These results offer actionable implications for reforming referral practices within child welfare systems.

Abstract Name: Binary Classification Model Performance Comparison: Evaluating the Accuracy of TabTransformers and Graph Neural Networks in Financial Fraud Detection

This abstract investigates how modern deep learning architectures can improve the accuracy and efficiency of fraud detection on highly structured tabular datasets. In the scientific literature, there remains difficulty in classifying financial fraud, as cross-feature interactions and rare positive labels render traditional models weak at tuning toward minority patterns. In an effort to address this performance gap, my project implements and evaluates two state-of-the-art approaches: the TabTransformer — a model developed by Google Research, fine-tuned for tabular datasets — and a Graph Neural Network that reframes transactions as formally relational structures. The TabTransformer utilizes attention mechanisms to learn consequential dependencies across categorical features in data, whilst simultaneously transforming continuous attributes. The TabTransformer architecture has demonstrated strong performance on imbalanced datasets, thanks to its ability to capture interactions that tree-based models often underserve. Similarly, GNN models transactions as functional nodes connected by attributes, enabling the system to identify community-level anomalies and relational fraud patterns that are not captured in row-wise modeling. The study will use the IEEE-Fraud dataset — a real, functional fraud dataset — to power the model training component for both approaches. They will be evaluated using AUC-ROC, precision, recall, and F1-score, with priority given to minority-class behavior. The aim of the study is not simply to determine which model yields the best performance, but to investigate the ‘why’ — particularly how the architectural differences yield the difference in classification. This research will add to the computing literature, contribute to ongoing conversations about the potential of deep learning for binary classification, and highlight practical methods for integrating transformer- and graph-based approaches into fraud detection systems.

Abstract Name: From Hypervigilance to Belonging: Examining Trauma-Responsive Teaching Approaches in College Learning Environments

The research investigates how trauma-informed teaching methods and faculty social-emotional learning training affect college students at Siena University by reducing their hypervigilance and improving their psychosocial adjustment. The survey results from 500 students show that psychological distress affects 38% of students who experience anxiety and 30% who experience depression and 80% who experience academic performance interference due to emotional difficulties yet only 11% of students seek help from their faculty members. The survey results show that students feel unsafe in their learning environment because they lack sufficient psychological and relational support. The study investigates how student hypervigilance and academic performance and help-seeking behavior relate to three independent variables which include trauma-informed awareness and faculty SEL competence and classroom safety perceptions. The research combines student focus groups with pre/post assessments and faculty training workshops to evaluate how trauma-responsive educational methods affect student mental health and academic success. The research investigates how better faculty emotional control and open communication and trauma-sensitive teaching methods affect

student alertness and their sense of community and academic involvement. The research findings will create a trauma-informed faculty resource model and establish institutional recommendations which can scale to different settings. The research outcomes match current national initiatives to establish wellness and equity and resilience frameworks throughout higher education institutions.

Abstract Name: Neanderthals and their Exhibitions of Fine Art: Unpacking Neanderthal Art on the European Continent

In this poster presentation, I will examine and convey information from research literature on the topic of European artifacts made by Neanderthals (*Homo Neanderthalensis*) that were artistically motivated in their creation, and highlight what this may mean to us (*Homo Sapiens*) comparatively in terms of evolution, behavioral patterns, and cognitive abilities. In my findings, I will present the multiple media found to have been used by Neanderthals to create art symbolically relevant to their lives, and how these creations show us that Neanderthals may have had a much more impressive set of complex mental capacities than what most have previously believed. This newfound potential for what the mental capacity of Neanderthals may have been opens the door to more speculative research and work on recreations of life for these ancient humans and will increase the amount and accuracy of our understanding of the past environments' influence on this species, as well as the interactions of *Homo sapiens* and Neanderthals with each other's species in prehistoric Europe.

Abstract Name: Evaluating AI-Driven 'Virtual Focus Groups' as a Tool for Social Science Research

Large Language Models (LLMs) continue to expand the range of tasks they can perform, yet their potential for generating qualitative, human-like insights remains underexplored. This project investigates whether LLM-driven "virtual focus groups" can serve as a preliminary research tool for social science and marketing studies at Minnesota State University Moorhead (MSUM). The goal is not to replace human subjects, but to assess whether AI agents, with carefully assigned demographic and personality attributes, can provide structured, internally consistent responses that help researchers refine interview prompts, anticipate divergent viewpoints, and prototype discussion scenarios before conducting in-person studies. To support this investigation, we developed a multi-agent system using Python, LangChain, LangGraph, and LMStudio for local inference. These tools allow us to instantiate several AI agents, each defined by a specific persona, and orchestrate their interactions through a deterministic discussion flowchart. LangGraph ensures strict turn-taking and predictable conversation transitions, while LangChain provides memory components, prompt

templates, and agent tools necessary for constructing realistic dialogue. This design moves beyond traditional prompt engineering by enforcing structured interaction rules that mimic the procedural dynamics of human focus groups. Preliminary observations indicate that the agents maintain coherent viewpoints and demonstrate distinguishable behavioral patterns across personas. These early results suggest that LLM-based focus groups may provide value as a rapid, low-cost method for testing research questions, surfacing thematic directions, and identifying potential challenges before engaging human participants. This work contributes to emerging conversations about how AI might support, not substitute, qualitative research by offering a controlled environment for exploring discussion dynamics in advance.

Abstract Name: How Superman Couldn't End the War: Nazi Prevalence in Superhero Comics

This research presentation examines the role Superman had in American propaganda against Nazi Germany leading up to and during World War II (1938-1945). In the realm of comic books, Superman is seen as a god among men, with the ability to take down superpowers in a way no mortal could. Jewish creators Jerry Siegel and Joe Shuster designed Superman as a response to growing antisemitism in Europe, representing the true power a Jewish man could hold, despite not being a Jewish character in the canon. However, Superman could not directly take down Hitler or the Nazis in the comics while continuing to positively promote the war effort as a growing symbol in American culture. Instead, publisher National Allied Publications, which would go on to become DC Comics, opted to use the character to encourage its American audience to support the war effort and the soldiers overseas, through comic strips like "Superman's Service for Servicemen." This historical work examines Superman-titled comics from this period alongside sources evaluating the history of the character in pop culture to demonstrate how Superman's character was utilized during World War II as an example of how American icons can be used to persuade public opinion and create impact during conflict.

Abstract Name: Case study of Chain link joinery

This research aims to study chain link joinery to explain its applicability in interior spaces at different scales. The use of chain links in creating various pieces of jewelry dates back centuries in Egyptian and Mesopotamian cultures. This type of joinery originated from the use of metal loops that are interconnected in different forms of jewelry. The use of chains in jewelry dates back in history and has significance in terms of symbolism and flexibility, and ornamentation. This paper seeks to identify the underlying system in the use of metal loops or chains. The study aims to investigate the applicability of chain link joinery from jewelry to architecture. With a methodology that examines how it can be applied at multiple scales from artifact level to enclosure, personal space to social space, this research documents the process diagrammatically and visually by studying plans and sections of the project. The project examines the levels of interlocking motion and

modularity in the joinery structure from three different levels of project scale: from object scale through modeling of an enclosure scale up through analysis of the spaces of different sizes. These levels demonstrate how the logic of connection and flexibility in the chain link system translates forms in relation to structure. This research demonstrates that the chain link jewelry joinery can be successfully transferred from the craft model to the larger-scale environment of interior spaces through the principles of repetition, connection, and modularity. The plans and sections create a rhythmic spatial connection through the arrangement of wall placement in spaces. The periodic interconnection system of joinery translates into larger-scale applications and provides spatial configurations allowing ornamentation and functional clarity in harmony. This research concludes that transforming jewelry techniques into interior architecture broadens the dialogue between craft and space.

Abstract Name: Caswell County on Trial: Race, Education, and Public Opinion in the Battle for Desegregation

Caswell County, located northeast of Greensboro, North Carolina, has a long, complex history clouded by pungent racial tension. Despite its historically strong African American presence in the area, the county's main city, Yanceyville, was depicted in the Depression-era Federal Writers' Project (FSA) and Works Progress Administration (WPA) as a white supremacist town, vehemently against civil rights for Black citizens. In 1958, and three years after the US Supreme Court demanded public schools desegregate with "all deliberate speed," Judge Edwin Stanley in *Jeffers v. Whitley* (1958) ruled that the Caswell County Board of Education fully controlled the speed of desegregation in their school district. In 1961, he further ruled in *Jeffers v. Whitley* (1961) that he could not enforce wholesale desegregation, despite admitting that racial discrimination continued within the county. The National Association for the Advancement of Colored People (NAACP) used these cases to prove integration was being slowed and sometimes blocked by legal procedures. My study explores the desegregation process in Caswell using NAACP records and examining the community's tension-filled history through interviews gathered for the FSA and WPA. I will inspect oral histories of Caswell's Black community, and compare and contrast Black residents' lived experiences with the county citizens' broad public opinions about desegregation during the 1950s and 1960s. My work will also reveal why the NAACP decided to support these cases in Caswell County and showcase the influence of public opinion on the issue of integration in North Carolina. By divulging into this "failure" of North Carolina education history, my project underscores the importance of telling the most complete stories in Black communities, allowing the exploration of race relations to take on a new level of complexity in the image of integration.

Abstract Name: AI-Driven Predictive Analysis of Airline Profitability Under Macroeconomic Trends and Sustainable Fuel Adoption

This present study explores how AI-enhanced predictive analysis can support strategic airline profitability planning under changing macroeconomic and sustainability conditions. The research introduces a conceptual decision-support framework: the Hybrid Predictive-Generative Scenario Engine (HPGSE) which integrates key economic indicators such as GDP growth, inflation, and fuel price volatility with sustainable aviation fuel (SAF) adoption while combining generative and predictive AI. Scenario-based analysis of optimistic, moderate, and adverse market environments, the framework illustrates how AI-generated insights can guide airline management decisions related to profitability, cost optimization, and sustainability investment.

Abstract Name: Learning Verified Compiler Optimization Heuristics for Lazification using a Code-Centric LLM

Compiler optimizations have long relied on handcrafted heuristics that often fail to generalize across programs or architectures. In this work, we ask whether a large language model (LLM) can learn verified optimization behavior for lazification, the transformation that converts eager call-by-value evaluation into deferred call-by-need semantics in C. We fine-tune a code-centric LLM on transformations produced by the Wyvern optimizer and integrate Alive2 into a feedback loop that enforces semantic equivalence for every generated rewrite. On the LLVM test suite, the model tracks Wyvern's optimization quality closely but applies fewer lazifications overall: roughly 76% of the benchmarks show a reduced transformation scope with slower overall runtimes, while about 9.8% achieve similar or modestly faster performance. No instance of over-lazification was observed. Structural analysis points to a cautious, memory-stable optimization style characterized by increased load and store operations but stable control flow, reflecting a preference for semantic safety over aggressiveness. Together, these results suggest that verified learning can support adaptive, correctness-preserving compiler systems grounded in formal guarantees.

Abstract Name: VT-109 Restores Alveolar Capillary Barrier after COVID-19 Related Lung Injury in Preclinical Models

Severe COVID-19 pneumonia causes lasting damage to the alveolar epithelium, leading to disruption of the alveolar-capillary barrier and pulmonary edema. The goal of this study was to determine whether VT-109, an allosteric inhibitor of end-binding protein 3 (EB3) that blocks pathological calcium signaling in endothelial

cells and stabilizes VE-cadherin junctions, can restore lung vascular integrity and support epithelial repair following COVID-19-related lung injury. Using preclinical models of SARS-CoV-2 pneumonia, we assessed pulmonary vascular leakage, lung edema, and structural injury to both endothelial and epithelial barriers. VT-109 treatment significantly reduced albumin extravasation, indicating restoration of endothelial barrier function. Importantly, VT-109 also promoted regeneration of damaged alveolar epithelial cells, resulting in improved lung structure and function. Mechanistically, VT-109 inhibited calcium-dependent NFAT/NFκB inflammatory signaling while activating the FOXM1-dependent regenerative program in endothelial cells, leading to reannealing of VE-cadherin junctions. Consistent with these findings, studies in a nonhuman primate model of COVID-19 demonstrated that VT-109 rapidly restored the pulmonary endothelial barrier, as reflected by reduced protein levels in bronchoalveolar lavage fluid. Together, these results identify endothelial calcium signaling as a key regulator of lung barrier dysfunction in COVID-19 and establish VT-109 as a promising therapeutic candidate capable of accelerating recovery by promoting vascular repair. Abstract Name: Real-Time Sensor System for Early Onboard Detection of Weather Phenomena

General Aviation currently lacks an onboard sensing system that alerts pilots to hazardous weather directly ahead of the aircraft, particularly microbursts and clear-air turbulence. This project introduces an aircraft-mounted detection pod that fuses LiDAR, automotive radar, and GNSS timing to estimate eddy dissipation and related features for real-time severity classification. A ROS2-based processing stack, coupled with Bayesian synchronization, aligns the asynchronous LiDAR and radar streams to the GNSS pulse-per-second signal, feeding a Random Forest model for classification. The aerodynamic fairing, designed in Fusion 360, maintains structural integrity in harsh environments and high airspeeds while preserving each sensor's field of view. The electrical system incorporates EMI/EMC-filtered power rails, and avionics integration supports existing cockpit interfaces for presenting turbulence labels to the pilot. Using mock data spanning four classes (none, light, moderate, severe), the current model achieves 67% accuracy and remains stable after applying hysteresis to suppress noise. Additionally, in-range buckets, derived from fused EDR-like metrics, further strengthen classification consistency. The full runtime stack operates on general-aviation-friendly hardware, providing timely, pilot-facing information that complements conventional weather products rather than replacing them, enabling improved in-flight awareness and decision-making. Prototype tests validate the system's GNSS-based synchronization, EMI robustness, and low-latency behavior, which aligns with a pilot's scan workload. The pod's modular design allows sensor swaps, bench testing, and maintenance, while its data interface enables seamless integration with moving maps, traffic overlays, and post-flight analysis tools. This study outlines a practical pathway toward real-time turbulence awareness in GA by combining off-the-shelf sensors, disciplined timing, and machine-learning algorithms within an aerodynamically efficient enclosure. Future work focuses on refining class boundaries and transitioning the system toward a scalable network capable of continuously feeding a real-time turbulence and hazard map for flight operations.

Abstract Name: Mitigating Knowledge Drain: A Case Study in Optimizing Workflow and Training in a High-Turnover, International Peer-Reviewed Undergraduate Science Academic Journal

Student-led organizations are dynamic hubs of experiential learning but are chronically plagued by "knowledge drain"—the loss of institutional memory and operational expertise due to high annual personnel turnover. This challenge is particularly acute for organizations like the Journal of Young Investigators (JYI), an international peer-reviewed undergraduate academic journal, where workflow consistency, scholarly rigor, and reasonable time-bound progress are paramount. This project sought to address the systemic inefficiencies resulting from this turnover by designing, implementing, and evaluating a multi-faceted suite of operational interventions. A longitudinal, single-organization case study was conducted over one year [January 2025-January 2026], with interventions implemented halfway through the year. Baseline metrics were established by analyzing the existing production workflow, including manuscript processing time and editor onboarding duration. Subsequently, a multi-part intervention was rolled out, including a revised hiring process, a modular asynchronous onboarding system, a formalized training program, and a transparent, Kanban-style workflow management board. The implementation of these systems yielded significant quantitative and qualitative improvements, including a 57% reduction in manuscript processing time and an average 47% decrease in the time required for a rejection or acceptance decision to be issued. Post-intervention conversations with staff members showed improved role clarity and more efficient transition periods for new hires. This systematic approach effectively mitigates the negative impacts of high turnover and offers a robust, transferable framework that can be adapted by other student-run initiatives to foster sustainability and operational excellence.

Abstract Name: Investigation of the Time Dependent Mechanical Properties Due to Elastin Degradations in Porcine Mitral Valve Anterior Leaflets (MVAL)

Mitral valve degeneration is a common age-related condition that progressively impairs cardiac function by reducing the flexibility and structural integrity of the valve leaflets. The mitral valve regulates blood flow from the left atrium to the left ventricle, and its dysfunction can lead to regurgitation, a condition in which the valve fails to close fully and allows backward flow into the atrium. A key contributor to this degeneration is the gradual breakdown of elastin, an extracellular matrix (ECM) protein that enables the valve leaflets to stretch and recoil during each heartbeat. As elastin deteriorates, mechanical loading shifts to stiffer collagen fibers, which can alter leaflet motion and contribute to disorders such as mitral valve prolapse. Previous research has characterized tissue behavior after complete or near-complete removal of elastin, but aging occurs as a gradual process rather than an abrupt loss of ECM components. As a result, little is known about

how progressive elastin degradation affects the mechanical properties of mitral valve tissue over time. This project addresses this gap by quantifying tissue-level mechanical changes in porcine mitral valve anterior leaflets following controlled, stepwise degradation of elastin. The study employs three methods: (i) biaxial tension and stress-relaxation testing of untreated leaflet samples to establish baseline properties, (ii) enzymatic treatment at defined time intervals to selectively degrade elastin, and (iii) repeated biaxial mechanical testing after each degradation stage. By correlating changes in mechanical response with the time course of elastin loss, this work aims to clarify how aging-like ECM remodeling alters valve function. These findings are expected to improve understanding of how degenerative processes develop and may ultimately inform more effective surgical repair strategies and computational models of valve mechanics.

Abstract Name: Design and Synthesis of Human Carboxylesterase 1 (CES1)-Specific Fluorogenic Chemical Tools Using Self-Immolative Linkers

Human carboxylesterases (CESs) are serine hydrolases that play key roles in the metabolism of drugs. One form, CES1, in particular is important in first pass metabolism of orally delivered drugs, as it is responsible for over 80% of the total hydrolytic activity in the liver. Despite the known importance of CES1, methods to study CES1 activity are limited. Our group has sought to address this by developing fluorogenic chemical tools that can report on CES1 activity in live cells. These current generation chemical tools involve directly linking the substrate to the fluorophore scaffold. The work presented here seeks to use self-immolative linkers to move the substrate away from the fluorophore, potentially increasing stability and allowing for a modular approach to expanding fluorophores that could be used to study CES1. Following successful synthesis and characterization by ¹H and ¹³C NMR, the probe will be evaluated for suitability for use in live cells to study CES1. Synthesizing efficient probes for CES1 detection would introduce a helpful diagnostic tool for analyzing activity in cellular samples.

Abstract Name: Spatial Omics Reveal Epigenetic and Dietary Modulation of ECM Remodeling in Liver Fibrosis

Chronic liver injury drives liver fibrosis, a progressive disease shaped by extracellular matrix (ECM) accumulation and dysregulation of epigenetic factors. Spatial omics-based research identifies key regulators but lacks spatial detail to capture the cell-protein interactions. This study employs computational analysis and immunofluorescence to identify 10 molecular markers across four mouse liver conditions: wild-type regular,

wild-type high-fat, fibrosis regular, and fibrosis high-fat. Pixel classification revealed phenotypic heterogeneity, with expression of ECM proteins, pan-cytokeratin, and α SMA in diseased liver tissues. Colocalization and correlation presented strong intracellular marker associations with variable extracellular interactions. Proximity mapping uncovered methylation-dependent patterns, where high methylation promoted proximity to fibrotic catalysts such as fibronectin and α SMA. High-fat fibrotic samples displayed increased VCAM-1 and pan-cytokeratin, associating diet with exacerbated injury. These results highlight how spatial omics integrate cellular interactions, ECM remodeling, and epigenetics to better understand liver fibrotic progression.

Abstract Name: Upgrading Wheat Straw Waste into Functional Fillers for Bio-based Polymer Composites

Wheat straw is an abundant agricultural residue that is typically underutilized because it contributes little to soil fertility and has almost no established market value. At the NIU Bioplastics Lab we explore wheat straw as a sustainable reinforcing and filler phase in biologically based polymers in order to upgrade this waste stream and reduce dependence on petroleum based plastics. We compounded ground wheat straw with poly methyl methacrylate (PMMA) and polybutylene adipate terephthalate (PBAT) at weight fractions of 30 and 50 percent and at two particle size ranges, below 250 micrometer and between 700 and 1440 micrometer. Before compounding, wheat straw was subjected to sodium hydroxide pretreatment, and the process conditions were systematically adjusted to minimize time and energy while maximizing interfacial adhesion. Treated straw and polymer were tumble mixed, melt compounded by extrusion, and then injection molded into specimens suitable for mechanical testing. Tensile tests show that adding 30 percent wheat straw in the 700 to 1440 micrometer range increases the ultimate tensile strength of PMMA from 27.0 to 37.5 MPa and of PBAT from 5.9 to 9.3 MPa. The modulus of elasticity of PBAT rises from 22 to 300 MPa, indicating substantial stiffening, while the modulus of PMMA decreases from 2.38 to 1.86 GPa, reflecting a tradeoff between strength and stiffness that guides further formulation work. Overall, our results demonstrate that properly pretreated wheat straw can significantly enhance the performance of PBAT and modify the mechanical response of PMMA, while valorizing an agricultural byproduct. This work supports the development of wheat straw reinforced biocomposites as promising candidates for partially renewable, mechanically robust plastic products.

Abstract Name: Removing "forever chemicals" (PFAS) from drinking water by filtration

Everyone should trust that their drinking water is clean. Per- and polyfluoroalkyl substances (PFAS), or "forever chemicals," are persistent pollutants used in products like non-stick cookware and firefighting foam. Their unique fluorinated structures allow them to persist in soil, groundwater, and drinking water systems

worldwide. They resist conventional water treatment and accumulate in the body, posing long-term health risks, such as cancer and developmental delays. Modern techniques for the removal of PFAS use anion-exchange resins (AER), which capture PFAS molecules through electrostatic attraction. To determine if alkyl length in amine-functionalized resins impacts PFAS capture, four ammoniated resins were prepared with alkyl lengths of one to four. Different bottles of ultrapure water were spiked with a representative mixture of three types of PFAS preceding the addition of each AER at a sorbent dose of 25mg/L. Following a three-day treatment of each resin, the samples were filtered to separate the resin from the solution. Solutions were analyzed using liquid chromatography–mass spectrometry (LC-MS) to quantify residual PFAS concentrations. An untreated control sample was included to ensure changes in concentration resulted solely from sorbents. Triethylamine-functionalized AERs showed the highest values for average percent capture of PFAS, followed by tripropylamine, tributylamine, and trimethylamine. AER selectivity for PFAS was greatest for PFBA, followed by PFOA and PFBS. Understanding structure–function relationships in AERs can inform the design of novel sorbents. By examining AER selectivity, these methods could be applied in large-scale water treatment plants to enhance PFAS removal and improve global drinking water safety.

Abstract Name: The Fusion of Indian Music and American Pop

The purpose of this project was to research different areas of Indian music - from the instrumentation and music theory to the cultural significance - and fuse it with American popular music, creating a modern and unique song appealing to various listeners. Being open to education and collaboration with other cultures encourages growth as a musician and presents the opportunity to explore new musical frontiers in the modern world. By studying the three main genres in Indian music: Hindustani classical, Rajasthani folk, and modern Bollywood, the various styles of Indian music were understood and interpreted in a unique way. Researching different types of Indian instruments allowed the instruments to be replicated or a similar sound to be recreated in the fusion piece. The cultural significance of specific types of Indian music were also taken into consideration and provided context for the song. For example, themes in folk music are often related to love so this theme was used as the main inspiration of the fusion piece. The form of Indian songs was also important. Depending on the genre, the song was structured in a specific way. For example, classical Hindustani music is broken into three sections: an introduction, the addition of percussion, and harmonic and rhythmic acceleration. This three-layer form was combined with the ABABCB song form (verse, chorus, bridge) to create the structure of the fusion piece. The process of creating the song strengthened technical skills while the research expanded appreciation of Indian culture. Furthermore, collaboration with Indian musicians and native-Hindi speakers provided authenticity and accuracy within the piece, especially in terms of foreign language pronunciation. The expected result of combining these areas of research with current skills in music production was the creation of an Indian-American pop song easily digestible for all types of listeners.

Abstract Name: Synthesis of Novel Anti-Melanoma Drug, A-11

Melanoma is one of the most aggressive forms of skin cancer and continues to pose a rising global challenge because it spreads quickly and has limited effective treatments. Natural products have emerged as valuable sources of new therapeutic leads. Several novel molecules derived from *Comptonia peregrina* (Sweet Fern), a traditional medicinal plant used by the Ojibwe people of Wisconsin, has been shown to possess skin lightening, anti-parasitic, anti-inflammatory and anti-tumor properties. Among the derivatives is A11, a patented molecule that inhibits melanin formation and slows melanoma cell growth. Previous biological studies demonstrated that A11 suppresses tumor development in melanoma-infected zebrafish embryos more effectively and with a drastically lower toxicity than FDA-approved drugs such as cobimetinib and dacarbazine. The goal of this research is to reproduce A11 through organic synthesis in gram-scale quantities to support further biological and pharmacological evaluation. The project focuses on improving each step in a multistep synthesis that modifies specific functional groups until the final A11 structure is achieved. Recent progress includes successful oxidation of the starting alcohol to aldehyde, verified by NMR spectroscopy, with yields improving from 17.1 percent to 35 percent after successive optimization trials. Optimization of the aldehyde synthesis displays a promising pathway toward efficient A11 production and provides valuable insight for improving later steps in the route. Completion of this work will enable preclinical testing, strengthen the compound's existing patent, and may attract pharmaceutical collaboration for large-scale production. This research aims to advance A11 as a safer and more potent anti-melanoma agent while highlighting the medicinal potential of naturally derived compounds in modern drug discovery.

Abstract Name: Does the Use of Jargon Affect Perceptions of Psychotherapists?

Psychotherapy theorists have cautioned that psychotherapist use of psychological jargon during treatment can lead to client confusion, reduced therapeutic connection, or poor perceptions of the therapist. Existing research assessing this issue has reported correlations between therapist use of jargon and client perceptions of the therapist. However, given the nonexperimental nature of these findings, it is unclear whether it was jargon use that led to differences in perceptions of the therapist. The aim of the present study is to use a randomized controlled design to assess the potential causal impact on client perceptions of therapist use of jargon. In this study, participants recruited from undergraduate psychology courses will be randomly assigned to listen to two sets of brief audio recordings, with each set of recordings emulating a therapist speaking during treatment sessions. In one set of these recordings the therapist employs technical or clinical jargon, whereas in the other set of recordings the therapist explains concepts in plain language. For half the participants, the recordings are of male therapists; for the other half, the recordings are of female therapists. Following listening to a set of recordings, participants will be asked to judge therapist empathy, the likely therapeutic alliance, and the perceived credibility of the treatment. Results will be analyzed by a language ' therapist sex analysis of variance, allowing for an assessment of the use of jargon and whether the effect of jargon depends on the sex of the therapist. If judgments of the therapist vary depending on the use of jargon, the study findings would provide evidence-based guidance for the language psychotherapists should consider using during treatment.

Abstract Name: Cracked! An Investigation Into Bone Fracture Patterns

Forensic anthropology plays a critical role in the justice system by interpreting skeletal injuries to reconstruct violent events. However, a significant challenge remains in scientifically linking specific bone fractures to the exact weapon used, a necessity for admissible court evidence. This ongoing research investigates the fundamental feasibility of this correlation, asking whether weapon types can be positively and reliably identified based solely on fracture patterns. The central hypothesis is that bone fracture patterns are replicable under controlled conditions and correlate predictably to variations in weapon type and velocity. To test this, the study utilizes a modified baseball pitching machine to deliver impacts to porcine femurs, selected as a human analog due to the comparable hardness of their cortical bone and for ethical considerations. Four weapon profiles were tested—a claw hammer, dowel rod, crowbar, and hatchet—impacting at speeds of 22, 33, and 44 mph. The methodology involves precise measurement of bone dimensions relative to fracture length, width, and type, with future microscopic analysis planned to identify micro-trauma. Expected results anticipate discernible statistical differences in fracture patterns across specific combinations of speed and weapon. Ultimately, this study aims to provide the necessary proof of concept that weapons leave distinct, reproducible signatures on bone, serving as a foundational step for future forensic interpretation in criminal trials.

Abstract Name: Reuse Room: Making Design Education More Sustainable and Equitable

Design students' curriculum is very different from a traditional major, leading to different challenges. Traditional students would generally have requirements like written papers, tests, and online assignments, while design students are often given assignments that result in physical projects, like models made unconventional materials, which need to be purchased. Because of this, a design student's curriculum is not cheap. Currently, students at the University of Kentucky are required to pay a mandatory fee of \$696 each semester, but students in a design program have an additional studio fee of \$686. Another issue is deciding what to do with the materials after the projects are complete. With materials often packaged in bulk and issues storing the remaining materials, this results in a lot of the material ending up in the waste stream or being improperly recycled. This begs the question of what can be done to lighten both the financial load and materials in the waste stream. A potential solution, which this project aims to explore, is a Reuse Room in the Gray Design Building. The first phase of the project is researching different existing centers in and around Lexington, which would help to understand how they run and what needs to be implemented in the Gray Design Building. The second phase would be working with both the faculty and student council in the College of Design to help plan and create a space in our building. The final phase would be the creation of this space. It would be executed with students and faculty in mind, dedicating the area to the offloading and obtaining of materials. It would also help to build a more conscious and equitable community in the design building. Ultimately, this could inform design education to be more sustainable and attainable, with less financial barriers.

Abstract Name: Synthesis and Investigation of Superconducting Properties of High Entropy Er123 Cuprate Ceramics

The RE123 (RE=rare earth element) compound is a common form of high-temperature superconducting (HTSC) cuprate ceramic with chemical formula REBa₂Cu₃O_{7-δ}. This compound makes an excellent superconductor due to its high critical temperature (T_c) in the low 90 Kelvin range, its high critical current density (J_c), stability, non-toxicity, and ease of synthesis. In this study, we aimed to investigate the effects of superconducting properties of ErBa₂Cu₃O_{7-δ} when doped with 4 other RE ions of varying ionic radius. Samples of high-entropy(HE) oxide-type ErBa₂Cu₃O_{7-δ} superconductors are prepared systematically using the solid-state reaction (SSR) method, and the sintering parameters for phase formation are determined. The crystal structure of the High Entropy-doped ErBa₂Cu₃O_{7-δ} superconductors investigated. We will discuss the superconducting properties of these materials using DC magnetization and compare their critical temperature (T_c), critical field (H_c), and critical current density (J_c). We determined that with increasing orthorhombicity, we saw an increase in T_c, H_c, and J_c. We plan to investigate this relationship further with more acute doping on the RE site.

Abstract Name: Obesity-Driven CNV and Gene Expression Changes in Danio rerio

Copy number variants have been associated with obesity linked, liver specific diseases such as NAFLD and Type 2 diabetes. However, obesity has never been investigated as a potential cause of copy number variant formation. Danio rerio (zebrafish) was used to generate a model of human obesity. Seventy-percent of zebrafish genes are similar to human genes with 84% of disease associated genes being present in zebrafish. Over the span of 6-8 weeks, zebrafish were fed an excessive diet of artemia to induce obesity, while control fish were fed normal diets. DNA and RNA were extracted from liver to investigate CNVs and expression differences in obese fish. RNA sequencing of zebrafish livers showed differential expression in immune and stress mechanisms including downregulation of the tumor suppressor IFI44L and overexpression of hemoglobin and C-Type lectin genes. Copy number variation was examined one mb upstream and downstream of gene transcription start sites to determine overlap with genes and direct and indirect effects. An eQTL using Spearman Rank Correlation was run to analyze associations between copy number variance and gene expression to determine CNV effects on gene expression in obese and normal fish. Together, these findings demonstrate that diet-induced obesity in zebrafish leads to metabolic suppression, immune imbalance, and altered epigenetic regulation patterns consistent with human obesity. This work reinforces the value of zebrafish as a translational model for understanding the molecular pathophysiology of obesity and its associated diseases.

Abstract Name: Self-Organized Oscillatory Dynamics of Liquid Nitrogen Bridges in Leidenfrost State

We report the discovery of a previously unknown nonlinear phenomenon: self-sustained periodic oscillations in cryogenic liquid bridges under Leidenfrost conditions. When liquid nitrogen is confined between shallow toroidal boundaries on a heated substrate, it exhibits remarkable dynamics—periodic shape oscillations, spontaneous symmetry breaking, and complete self-organized cycles of bridge expansion, bubble nucleation, splitting, and reconstitution. This discovery represents a new class of interfacial instabilities in evaporating systems. Our experimental platform combines precision temperature control with high-speed imaging and particle image velocimetry (PIV), capturing the full spatiotemporal evolution of these complex phenomena. The high-speed movies reveal intricate vortex structures and traveling waves that drive the oscillatory behavior through thermo-mechanical coupling between continuous evaporation, vapor flow dynamics, and capillary pressure gradients. We developed a complete mathematical physics model employing nonlinear differential geometry for capillary pressure calculations and lubrication approximation for vapor layer dynamics. The model reveals soliton-like structures governed by coupled nonlinear partial differential equations, successfully predicting the observed oscillation frequencies and instability thresholds. The agreement between theory and experiment validates our framework for describing this emergent behavior. This isolated Leidenfrost environment provides a unique testbed for studying interfacial instabilities with applications spanning aerospace thermal management, microelectronics cooling, microfluidic systems, and potentially biological pattern formation, as the dynamics exhibit striking similarities to cytokinesis, a cell division process that remains poorly understood despite recent observations of similar oscillations in cells with defects.

Abstract Name: Following Collagen Deposition During Zebrafish Development Using CRISPR-mediated Integration

Collagen IV (Col4a1) is a key extracellular matrix protein whose localization informs its role during vascular development and function. Using CRISPR/Cas9-mediated fluorescent protein tagging in zebrafish (*Danio rerio*), we integrated the Venus reporter into the Col4a1 locus via plasmid injection at the single-cell stage.

Using fluorescent microscopy, we screened embryos at 48 hours post-fertilization and observed the expression of Col4a1-venus fusion. We observed Col4a1-venus deposition around muscle cells and blood vessels during early development, highlighting its contribution to extracellular matrix organization. Current efforts focus on isolating a stable transgenic line to track Col4a1 dynamics during heart development and regeneration. This approach establishes a platform for visualizing collagen IV in vivo and advancing our understanding of its role in development and regeneration.

Abstract Name: Development of a Method for Selective Retention of Fragrance Components on Activated Carbon: Implications for Volatile Organic Compound Preservation

Volatile organic compounds (VOCs) are key components of fragrance formulations and personal care products. They can serve as valuable chemical signatures in forensic investigations involving clothing, personal items, and environmental residues. However, their high volatility and differential adsorption behavior present substantial challenges for reliable evidence of collection, transport, and downstream analysis. Traditional sampling approaches, such as solid-phase microextraction (SPME), offer high sensitivity but require specialized equipment, rapid deployment, and technical expertise. These limitations have increased interest in cost-effective and field-deployable alternatives, that can offer a similar level of reliability to current testing standards, leading to this investigation of activated carbon, which is used in arson investigations but not explored in fragrance-related VOC sampling. This research aims to evaluate the use of active carbon strips as a more cost-effective alternative to capture VOCs associated with clothing evidence. This study assessed the selective retention and preservation of fragrance-derived VOCs on activated carbon to better understand the influence of sampling media on volatile evidence. Activated carbon strips were exposed to cotton knit fabric samples treated with commercial fragrances under controlled laboratory conditions. VOCs were eluted from the carbon strips using solvent and analyzed by direct injection into a gas chromatography–mass spectrometry (GC–MS) system. Resulting chromatograms were compared with direct injections of 1-10 diluted fragrance standards, demonstrating that this method enables capture of fragrance compounds. This work contributes to the development of more accessible and reliable GC–MS based methodologies for preserving and analyzing VOC evidence, particularly for identifying fragrance components in trace forensic samples such as clothing fibers, packaging materials, and environmental residues.

Abstract Name: Assessing Xurography as a Low-Cost Fabrication Technology for Dielectric Spectroscopy

Microfluidic platforms provide controlled environments for manipulating biological cells and are often paired with dielectrophoresis (DEP), a technique that generates forces on polarizable particles in nonuniform electric fields. The direction and magnitude of DEP depend on cellular electrical properties, suspending medium, and the applied AC frequency. The point at which the DEP force becomes zero, the crossover frequency, serves as an indicator of the cell's dielectric behavior and can reflect underlying physiological conditions, offering potential options in diagnostic applications. Despite the value of DEP-enabled devices, many institutions lack access to conventional microfabrication due to its cost and equipment requirements. This work explores Xurography as a low-cost alternative capable of producing microdevices suitable for dielectric characterization. Microchannel layouts were designed and cut from laminating films with a CAMEO cutter, layered with platinum electrodes, and sealed via thermal lamination. To validate our technology, packed red blood cells suspended in sugar solutions at varying conductivities were introduced into these devices, and a 10 Vpp signal was applied across 60–80 μm electrode gaps while the AC frequency was incrementally adjusted. Visual assessment of the transition between positive and negative DEP enabled determination of the first crossover frequency. These measurements will be used to evaluate the reproducibility and reliability of Xurography-fabricated devices, providing insight into whether this fabrication method can support accessible, cell-focused microfluidic research in low-resource environments.

Abstract Name: The Evolution of Tea's Influence in Chinese Culture: Religious, Philosophical, and Artistic Dimensions from Antiquity to the Global Era

Camellia sinensis, commonly known as tea, has been a cornerstone of cultural development in China, shaping religious beliefs, artistic expression, and social norms from China's ancient past to the present, where its impact can still be found in every country it inhabits. Past research primarily explored tea's economic, agricultural, biological, and religious contributions; its more holistic cultural significance has received less thorough attention. This failure has caused tea's infiltration in every aspect of Chinese life to remain in the shadows. I aim to address this gap with historical documentation such as ancient Chinese texts and drawings, linguistics, and cultural anthropology, as well as archaeological findings and trade route records to trace tea's evolution from its mythic discovery to its national popularity. Historical texts are indicative of tea's ability to set and change norms of refinement, mindfulness, entertainment, and social connection, particularly in the Tang and Song Dynasties. More recent sources encapsulate tea's role in modern China in comparison to the past, where it was a symbol of status and prestige amongst the elites. Now, tea has become a common commodity that unites instead of divides, with each generation making it their own. As a universal bridge, tea has traveled from China to countries around the world. From the formal Japanese Tea Ceremony to the more casual British Afternoon Tea, new ways of enjoyment tailor the tea experience to reflect each country's own unique society, leaving behind its pleasant aftertaste on the palates of all who have been satisfied. Thus, tea remains both widely accessible and enduringly significant as a subject of cultural engagement and study, as understanding its role in Chinese culture provides insight into the historical and social foundations of customs and norms that may otherwise appear unusual or arbitrary. This, in turn, fosters greater cross-cultural understanding and appreciation.

Ethan Smith

Discipline: English and Literature

Authors:

Abstract Name: Domination in the Shadows

Domination in the Shadows Name: Ethan Smith Major Department(s): Philosophy (Psychology & Creative Writing minors) Project Abstract My capstone research in PAR 400 philosophy of democracy and power examines domination, wealth inequality, and freedom in modern society. Reading from Jeffrey Winters and Alex Gourevitch, I argue that capitalism hides domination through wealth defense and structural inequality, much like Plato's Allegory of the Cave conceals with shadows. I am requesting a CHSSA Research Grant to present this project at a regional philosophy conference, submit it for undergraduate publication, and study historical sites abroad in Greece. This support will expand my paper and prepare me for graduate-level research. Research Project Description My research develops from my PAR 400 capstone seminar, where I examine the relationship between domination and freedom in politics. Winters argues that modern democracies are structured by "wealth defense," where elites consolidate resources to preserve power. Gourevitch extends this by showing how structural domination persists even without overt coercion. I connect these analyses to Plato's Allegory of the Cave, where individuals mistake shadows for truth. This metaphor highlights how systemic domination today can obscure genuine and true freedom by presenting inequality as natural or inevitable. I will adapt the essay into a presentation for the North Carolina Undergraduate Research Conference (NCURC). I plan to produce a companion creative nonfiction essay that integrates travel experiences in Greece with philosophical reflection, linking Socratic sites to modern debates on domination.

Abstract Name: Sigma-1 Receptor Potentiates Synaptic Glutamate (NMDA) Receptor Channel Activity

Background: The α -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA) and N-methyl-D-aspartate (NMDA) types of glutamate receptors are central mediators of excitatory neurotransmission and are essential for synaptic plasticity mechanisms required for learning and memory formation. Precise regulation of NMDA receptor (NMDAR) function is critical for maintaining neuronal communication and cognitive stability. The sigma-1 receptor (σ 1R), an endoplasmic reticulum chaperone enriched at mitochondria-associated membranes, has been implicated in modulating glutamatergic neurotransmission and cognitive processes. The σ 1R activation enhances glutamate release and promotes long-term potentiation (LTP), a cellular model of memory. However, its direct impact on synaptic NMDA receptor channel function remains not fully elucidated. We hypothesize that σ 1R serves as a positive modulator of synaptic NMDA receptor function, thereby supporting enhanced synaptic plasticity and memory processes. Methods: Single-channel electrophysiological recordings were performed on hippocampal synaptosomal NMDARs using artificial bilayers and patch-clamp electrophysiology to assess channel properties, including open probability, conductance, and interactive channel gating, under control conditions and following σ 1R agonist treatment. Results: σ 1R activation significantly increased NMDAR mean open probability and enhanced interactive channel gating. These changes are consistent with improved synaptic efficacy and facilitation of plasticity

mechanisms in the presence of σ 1R agonist. Conclusion: These findings demonstrate that σ 1R activation positively modulates synaptic NMDA receptor channel function, suggesting a mechanistic link between σ 1R signaling and enhanced synaptic plasticity. Thus σ 1R represents a promising therapeutic target for mitigating cognitive decline and neurodegenerative disorders by modulating glutamatergic neurotransmission.

Abstract Name: Think bright colored food: A Qualitative Study of People Living with ALS Who Followed the MIND Diet in a 7-Week Pilot Study

Nutritional deficits are a problem for those with ALS (Amyotrophic Lateral Sclerosis) as their disease progresses. For people with ALS (pALS), adequate nutrition to support the body is extremely important. ALS is a disease that causes weight loss and muscle wasting. An important aspect of adequate nutrition is the individual's attitude towards diet. If the individual does not value the importance of diet and the types of foods that support their body, then they will likely not achieve proper nutrition. This study aims to identify the attitudes of those with ALS in adhering to a neuroprotective nutritional pattern called the Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) diet. Participants included 11 pALS who followed the MIND diet for 7 weeks. Using open-ended survey questions each week, participants were asked about their experience following the diet. Their responses were coded, and common themes were identified as follows: physical barriers to preparing foods, symptoms impacting food consumption, and the importance of support. These trends show common challenges faced in this population in following the diet and commonly held attitudes. These results can be used to help address the challenges and improve outcomes of pALS in eating well.

Abstract Name: Faith On Display: Investigating Religious Discrimination in the Hiring Process

This study investigates whether wearing a visible religious symbol affects perceptions and suitability of an applicant's qualifications during the hiring process. The research addresses the ongoing issue of religious discrimination in employment settings and its implications for fair and unbiased hiring practices. Using the online platform Qualtrics, 150 participants reviewed a job description for an Engineering-in-Training position and evaluated two applicant headshots and résumés presented as, Applicant A and Applicant B. Applicant A, who was randomly assigned to wear a necklace pendant featuring a Cross, Star of David, the word "Allah" in Arabic, or no symbol, and Applicant B, who wore no symbol. Participants rated each applicant's suitability for the role, indicated their hiring preference, and provided reasoning for their decisions. Based on previous literature, it was hypothesized that applicants displaying Christian symbols, such as a Cross, would be evaluated more favorably and viewed as a better fit for the position than those wearing non-Christian symbols. It was also expected that individuals would be less willing to wear visible religious symbols to an interview if they believed doing so could reduce their likelihood of being hired or viewed fairly. Preliminary

results suggest that wearing a religious symbol does not significantly influence hiring outcomes. Instead, participants emphasized applicants' résumés and qualifications as the primary factors guiding their decisions. These findings indicate that, within this sample, visible religious symbols may not disadvantage applicants as strongly as previous research has suggested, underscoring the importance of continued research on subtle forms of religious bias in professional contexts.

Authors:

Abstract Name: The Muny: A Unique, Audience-Centered Experience

The Muny of St. Louis, Missouri (1919-), is an extremely unique theater, not just for being the oldest and largest musical outdoor theater in the United States, but also because of its mission. According to Gabe Hartwig, the Muny's Communications and Public Relations Manager, their goal is "to enrich lives by producing exceptional musical theatre, accessible to all, continuing its remarkable tradition in Forest Park." The employees want to share live theatre in a way that allows all kinds of audiences to see it. There are no exclusive or superiority factors at play, just showcasing theatre for the audience, their number one focus. There is no emphasis on ticket sales or aesthetics, but instead on the audience and their experience. This is done in multiple ways, but the main reasons I will discuss are the free seats they offer, relatively inexpensive tickets and season passes, and constantly renovating and updating the space to improve the audience's satisfaction. I plan to demonstrate this using a variety of sources, but specifically articles detailing different renovations, quotes from the staff, including an interview with a current staff member, and the overall experience the theater provides. I will also utilize the Muny's docuseries, Moments, which touches on everything one should know about this unique theater. In addition to those, there will be smaller, yet still impactful mentions of ways that the Muny is so unique, such as revising/rewriting popular Broadway shows so their specific audience gets a one-of-a-kind experience. Ultimately, I plan to discuss the Muny's profound understanding of the concept and purpose of live theatre and their execution of it; prioritizing the audience above all else.

Abstract Name: Validating Digital Twins: How Photorealistic 3D Map Tiles and OpenStreetMaps Perform in Airflow Simulation

Developing an intricate, geographically precise, and immersive digital depiction of actual streetscapes is crucial for progressing human-focused infrastructure design. This research builds upon an earlier project that integrated a cross-platform workflow, utilizing Photorealistic 3D Tiles (P3DT), OpenStreetMap (OSM), Blender, and Unity to generate a geographically aligned digital twin for traffic and agent-based simulations. The primary focus of the present study is on implementing rigorous geometric validation for this previously developed digital twin. This research conducts an in-depth comparison between a complex building model derived from P3DT and a generalized semantic model derived from OSM within a Computational Fluid

Dynamics (CFD) simulation framework. The methodology involves experimenting with these distinct geometries within the cloud-based environment known as SimScale. On this platform, the models are subjected to Lattice Boltzmann Method (LBM) simulations to examine airflow dynamics, thereby ensuring the accuracy of the data source based on the simulation outcomes. This project validates the application of P3DT in LBM modeling, successfully connecting visual realism with reliable, high-fidelity technical evaluation. This research establishes a foundational engineering-based approach to urban development that emphasizes environmental factors, including wind flow patterns, pedestrian comfort, and hurricane impact analysis.

Authors:

Abstract Name: Agape Sanctuary: A Center for Rest, Reflection & Reconnection

Constant pressure to stay busy can drain and distract from peace, leaving little space for spiritual reflections. This project aims to help guests disconnect from their daily routines, ground themselves in the present, and engage with the Lord in meaningful ways. The facility is designed for individuals who are open to fellowship and deepening their spiritual relationship. Gallup reports that 68 percent of Americans identify as Christian, while weekly service attendance continues to decline, and public spaces dedicated to fellowship with the Lord outside church settings remain limited. A communal sanctuary offers a purposeful solution by providing a place to seek God's presence and restore well-being through supportive amenities beyond the traditional church environment. This approach aligns with place attachment theory, which describes the emotional bond individuals form with physical environments, and how people connect and feel a sense of belonging to places. Research methods include reviewing case studies on spiritual architecture, interviewing regular and infrequent churchgoers, observing interior environments during site visits, and analyzing the project site to understand its scale and context. This facility proposes lodging and a range of amenities, including fine dining, a music hall, fitness and spa, a retail shop, and a nature-inspired sanctuary. Natural elements throughout the indoor and outdoor environments, along with integrated ponds, support mental wellness and reflect attention restoration theory, which explains how nature helps restore focus and reduce cognitive fatigue. A dedicated sanctuary building offers space for prayer, meditation, and spiritual connection. Together, these features create a restorative setting for guests seeking spiritual and personal renewal.

Abstract Name: Examining The Kyanite Mining Corporations Land Use Change and Mine Reclamation

The Kyanite Mine, located in Buckingham County, Virginia is one of the largest kyanite deposits in the United States. Over its history, Kyanite Mine Corporation has been recognized for its environmental stewardship efforts and success in reclamation. This study employed the use of remote sensing methods to evaluate the surface water quality of tailing ponds and the land use changes at the Kyanite Mine. Landsat imagery obtained from the USGS' Earth Explorer program were used to assess vegetation health and surface water quality over a 35-year period using the The Normalized Difference Vegetation Index (NDVI),

Normalized Difference Water Index (NDWI) and a novel machine learning algorithm that was used to evaluate land use and land cover change. The NDVI and NDWI analyses for 1990 and 2025 reveal substantial improvements in both vegetation condition and surface water characteristics across the study area. NDVI values increased from 0.35 in 1990 to 0.59 in 2025, indicating a marked enhancement in vegetation density and overall ecosystem health over the 35-year period. Parallel increases in NDWI suggest that surface water bodies have become more persistent and hydrologically stable, reflecting improved water availability or quality. Together, these trends point to long-term positive environmental change and highlight the effectiveness of remote sensing indices for monitoring landscape-scale ecological dynamics at the Kyanite Mine.

Abstract Name: Developing a dTAG-Based Degradation System for the tRNA Methyltransferase TRMT10B

Modifications to tRNA often impact tRNA stability and function. Defects in tRNA modifications have been associated with different human diseases, including developmental disorders, metabolic disorders, and cancers. Members of the Trm10 family are tRNA N1-methyltransferases that modify purines at position 9, and mutations in TRMT10A and TRMT10C have been linked to impaired brain development and mitochondrial dysfunction, respectively. The addition of N1-methyladenosine at position 9 in tRNAs (m1A9) is catalyzed by the tRNA methyltransferase, TRMT10B. Compared to other enzymes in the Trm10 family, TRMT10B has been significantly understudied, including its mechanism, substrate specificity, and general cellular effects. Interestingly, high TRMT10B expression is associated with favorable patient outcome in several cancer types. TRMT10B is endogenously expressed in a range of cell lines, including HEK293T cells. Our system to study this enzyme incorporates the dTAG design, which attaches a small tag (FKBP12F36V) to a protein of interest, allowing rapid and reversible loss of that protein upon addition of a dTAG degrader molecule. Our objective is to generate a TRMT10B degradation cell line using the dTAG system to understand the impact of TRMT10B on translation and tRNA stability. Using Gateway cloning, we inserted TRMT10B into a dTAG vector and transiently transfected the FKBP12F36V-HA-TRMT10B-containing plasmid into HEK293T mammalian cells. Subsequently, we confirmed the expression of the fusion protein using western blotting with antibodies targeting the HA tag and TRMT10B. Probing with both HA and TRMT10B antibodies produced a strong band at approximately 58 kDa, validating the successful expression of the fusion protein. Ongoing experiments are aimed at confirming the degradation of TRMT10B by dTAG with western blotting and analyzing translational changes with puromycin labeling. Establishing this dTAG-based TRMT10B degradation system will provide a tool to study the impact of TRMT10B on tRNA stability and cellular processes to better characterize an understudied tRNA methyltransferase.

Abstract Name: The Effects of Live versus Recorded Music on the Engagement of Adults with Intellectual Disabilities in Music Therapy

For decades, music therapists have utilized music interventions to assist individuals with disabilities in achieving non-musical goals, including behavioral regulation, communication, motor control, cognitive skills, emotional expression, and social skills. While a large body of research in music therapy concerns children with intellectual and developmental disabilities (IDD), few studies focus on adults with IDD. In addition to research, this population is often excluded from healthcare benefits, public education, and community services. The purpose of this observational study was to examine the engagement levels of adults with IDD during active music-making interventions to determine if the presentation of music, live or recorded, changes these levels. A board-certified music therapist performed active music-making interventions using either live or recorded music for participants ($n = 178$) in a summer camp program for people with IDD. Participant engagement was operationally defined and recorded as active, passive, or not engaged using a time-sampling methodology. A two-sample independent χ^2 test was utilized to examine the difference in engagement of participants during music therapy interventions between live and recorded music presentation style. An overall significant difference was found, $\chi^2(2, 796) = 30.58, p < .0001, V = .196$. Post hoc 2x2 contingency table χ^2 tests were significant ($p < .04$). Descriptive results showed that while active engagement levels remained similar for both modalities, live music interventions produced higher levels of passive engagement and held participants' engagement for a longer duration than recorded music interventions. These data provide applicable insights for clinical care informing intervention development and implementation for music therapists and other care professionals as they seek to engage adults with IDD and provide effective services.

Abstract Name: Insecure Attachment: Implications for OCPD Features among University Students

Background: Obsessive-compulsive personality disorder (OCPD) is characterized by preoccupations with orderliness, perfectionism, and control, all of which reduce flexibility, openness, and efficiency. Bowlby's attachment theory suggests that personality disorders (PDs) can result from childhood deprivation of care or instability in the relationship with a primary caregiver. Specifically, attachment issues (i.e., insecure avoidant attachment) are considered to be a salient etiological factor in the development of OCPD. This study aims to expand on the relationship between adult attachment styles and OCPD features and symptoms. Method: The sample consisted of 317 undergraduate students from a mid-Atlantic liberal arts university ($n = 232$ females and $n = 85$ males; mean age = 19.32 years, $SD = 1.33$). Participants completed an online survey containing demographic questions, the Pathological Obsessive-Compulsive Personality Scale (POPS) to assess maladaptive obsessive-compulsive traits, and a forced-choice measure of adult attachment styles (Secure, Avoidant, Anxious-Ambivalent). Results: A series of 2 (biological sex) x 3 (adult attachment style) factorial ANOVAs assessed the effects of biological sex and attachment style on POPS total and subscale scores. Significant main effects were found for biological sex on Emotional Over-Control ($p = 0.007$), Maladaptive Perfectionism ($p = 0.036$), and Difficulty with Change ($p = 0.004$). Significant main effects for adult attachment style were found on the POPS total score ($p < 0.001$) and the following subscales: Rigidity ($p < 0.001$), Emotional Over-Control ($p < 0.001$), Maladaptive Perfectionism ($p < 0.001$), Reluctance to Delegate ($p < 0.001$), and Difficulty with Change ($p = 0.014$). Discussion: The findings support previous research linking OCPD to high attachment avoidance. Specifically, participants with an Avoidant attachment style scored higher on all POPS subscales compared to those with a Secure attachment style. Future research with a more diverse sample could provide further insights into the relationship between attachment and OCPD features.

Abstract Name: The Effects of Light Wavelength on the Growth of Lettuce (*Lactuca sativa*) Cultivated in Martian Regolith

As space missions progress toward Martian exploration, developing reliable methods for producing fresh food in extraterrestrial environments has become increasingly important. Martian regolith presents major challenges for plant cultivation because of its high alkalinity, poor water retention, nutrient deficiencies, and the presence of perchlorates. Lettuce has been shown to be a strong candidate crop for space agriculture because of its rapid growth cycle, nutritional value, and successful performance in controlled-environment studies. Light quality is a major environmental variable influencing plant development, particularly in artificial growth systems required for space exploration. This study aims to investigate how different wavelengths of light such as full-spectrum, red (~660 nm), blue (~450 nm), and combined red/blue light will affect the growth and physiological responses of butterhead lettuce (*Lactuca sativa*) cultivated in a Martian regolith simulant amended with topsoil, perlite, and worm castings. Plants will be grown under controlled temperature and humidity conditions, with identical soil composition, watering schedules, and photoperiods across all treatments. Growth will be evaluated through weekly measurements of plant height, leaf number, leaf surface area, soil pH, electrical conductivity and chlorophyll content. At harvest, fresh and dry biomass will be recorded. Statistical analysis will compare mean growth responses among treatments to determine whether specific wavelengths improve plant performance in modified regolith. Data collection is ongoing, so results are still forthcoming. However, based on previous research, it is anticipated that combined red and blue wavelengths will promote higher biomass accumulation and chlorophyll development than single-wavelength treatments or full-spectrum controls. Findings from this study may inform future controlled-environment strategies for producing nutritious, reliable crops on Mars.

Abstract Name: The Influence of Self-Esteem and Adult Attachment Styles in BDD Symptoms and Severity in a Non-Clinical Sample

Background: Body dysmorphic disorder (BDD) is a disorder that is characterized by a preoccupation with an imagined or slight defect in appearance. The associated preoccupation with appearance flaws usually focuses on the face or head, but can be related to other body areas/parts as well. A key issue is how strongly the negative evaluation in the physical appearance domain associated with BDD is accompanied by low self-esteem and general feelings of unworthiness. It has been suggested that the psychopathological process in BDD may depend on the mode of attachment—specifically insecure attachment. Therefore, a key aim of this study was to assess the effects of self-esteem and attachment styles on self-reported frequency/severity of

BDD symptoms. Method: The sample consisted of 206 undergraduate students (n = 151 females and n = 55 males), with a mean age of 19.19 years (SD = 1.29). Measures included: Demographic items; the 61-item Body Dysmorphic Disorder Symptom Scale (BDD-SS); the 10-item Rosenberg Self-Esteem Scale (RSES; Self-Report Version); and a four-group model of adult attachment styles. Results: Two 2 (biological sex) x 2 (self-esteem low vs. high) x 4 (attachment style) factorial ANOVAs were performed to assess the influence of self-esteem (low vs. high) and attachment styles on BDD-SS symptom and severity scores. For BDD-SS symptom scores, all main effects were significant (p's < 0.05). For BDD-SS severity scores, there were significant main effects for self-esteem and attachment style (p's < 0.001). Discussion: Consistent with previously published studies, data from this study also demonstrate that low self-esteem is related to BDD. Moreover, this study further suggests that BDD symptomatology perhaps impacts self-esteem more strongly in women. Similar to other studies, these data suggest that both Secure and Dismissive attachment styles are associated with a more positive body image compared to Preoccupied and Fearful attachment styles.

Abstract Name: Microrobot-Assisted Delivery of Circular RNA-Lipid Nanoparticles for Lung-Associated Diseases

Respiratory diseases are more prevalent than ever, driving high demand for new therapies, but thick airway mucus is a major barrier that traps particles and inhibits pulmonary drug delivery. To overcome this problem, we developed biodegradable magnetic microrobots (μ bots) that swim in viscous environments under a rotating magnetic field. These μ bots can guide lipid nanoparticles (LNPs) loaded with circular RNA through complex fluids, presenting a promising strategy for enhanced drug delivery in the lungs. Biodegradable μ bots with differing shapes were fabricated with contact photolithography using poly(β -amino ester) and a photoinitiator. Magnetic field-responsiveness was introduced by embedding superparamagnetic iron oxide nanoparticles (SPIONs) into the μ bots or coating them with an iron film using electron-beam evaporation. LNPs containing circular RNA were subsequently attached. We assessed μ bot behavior in mucus-like fluids along with in vitro payload release, transfection, biocompatibility, and biodegradability. Magnetic μ bots swim in precise trajectories under rotating fields, demonstrating velocities dependent on their environment. Based on our design, we expect LNP- μ bots to remain stable during μ bot actuation, enabling payload release only at the desired target. We also anticipate that degradation of the μ bots can be adjusted by tuning the diacrylate-to-amine molar ratio in the resin, while retaining biocompatibility in vitro. LNP composition is being optimized to enhance μ bot attachment, and successful cell transfection with circular RNA within an acceptable cell viability range was accomplished in vitro. Finally, extended protein translation with circular RNA compared to linear messenger RNA was demonstrated in vitro. By optimizing LNP movement through complex environments and demonstrating sustained protein expression with circular RNA, this system offers a promising path toward more effective gene therapies for lung disease.

Abstract Name: Creation of an Enhanced Germline-Specific RNAi Strain in *C. elegans*

In order to study the function and expression of the *odd-2* gene in the germline of *Caenorhabditis elegans*, we have been working to create a germline-specific RNA interference (RNAi) strain. We crossed the DCL569 and WM171 strains to create a new strain with a *rde-1* loss of function mutation, a germline-specific *sun-1P::rde-1* insertion, and an *eri-5* mutation that increases RNAi sensitivity. In this new strain, RNAi should only work in the germline, and the effect should be enhanced over the DCL569 strain alone. Genotyping was done via PCR. Primer optimization was successful for *rde-1*, *sun-1P::rde-1*, and *eri-5* mutant primers. However, after various PCR techniques and primer combinations to detect the *eri-5* wildtype (WT) sequence produced a positive band in the mutant strain, the WM171 strain was deemed problematic. After the possibility of contamination had been accounted for, Sanger sequencing was utilized. The sequencing confirmed the presence of the *eri-5* deletion in the WM171 strain but also revealed WT sequence when the WT primers were used. This suggests that there could be rearrangement that occurred during mutagenesis, unreported balancers, or heterozygosity occurring in the WM171 strain we received. Because the *eri-5* mutation could not be confirmed to be homozygous in the new strain, it cannot yet be considered a fully functioning enhanced germline-specific RNAi strain. Future directions include using long read nanopore sequencing to sequence the DNA to look at specifically where the WT sequence is. Another approach would be to use multigenerational genotyping techniques to check for the presence of homozygous *eri-5* mutant individuals within the strain. The construction of this strain will allow for greater ability to study germline-related genes in the future.

Abstract Name: Unveiling ADCY3 as a Central Olfactory-Related Biomarker Gene and Potential Therapeutic Target in Kidney and Colorectal Cancers

Olfactory genes, usually studied for their role in smell, are increasingly linked to cancer signaling. This project examined whether a shared olfactory-related hub gene connects kidney and colorectal cancers and whether it could be drug-targetable. Public GEO datasets for renal cell carcinoma and colorectal cancer were analyzed against a set of 489 olfactory/cilia genes. Differential expression, protein-protein interaction mapping, and network-ranking identified a 12-gene olfactory signature common to both cancers, with ADCY3 (Adenylyl Cyclase 3) emerging as the top hub gene across all analyses. External cancer portals confirmed that ADCY3 is broadly overexpressed in both tumor types, though not predictive of overall survival. Drug-repurposing screens using an FDA-approved drug database highlighted three cannabinoid small molecules, rimonabant, cannabidiol, and dronabinol, as ADCY3-linked candidates. Molecular docking and ADME-tox predictions indicated favorable binding and acceptable oral drug-likeness and safety profiles. Overall, the study identifies ADCY3 as a conserved olfactory-related hub gene in kidney and colorectal cancers and suggests that these existing cannabinoid drugs warrant future experimental testing as potential ADCY3-targeting therapies.

Abstract Name: Heterogeneous Catalysis: Methanol Decomposition on Platinum

Catalysts play a substantial role within the chemical industry, as their ability to conserve energy and increase the efficiency of chemical reactions makes them a vital component of modern science and technology. Platinum is a great example of this: its use in catalytic converters is what makes it possible for motor vehicles to run without expelling poisonous gases. While much is known about the capabilities of catalysts, there is a poor understanding of their fundamental chemistry. Studying how metals like platinum interact with common industrial materials will develop this understanding, allowing for greater efficiency and effectiveness. A common industrial chemical is methanol, as it is often seen as a reactant, product, and intermediate in industrial processes. It is a very simple molecule with common atomic bonds, which makes it a strong candidate for studying its interaction with platinum. When exposed to platinum, methanol decomposes to form carbon monoxide; however, little is known about the intermediates that form and the kinetics behind this reaction. To study this, a platinum crystal was placed in an ultra-high vacuum chamber, the surface was atomically cleaned to remove surface contamination, and it was exposed to methanol gas. Temperature-programmed desorption and sum-frequency generation spectroscopy were then used to determine what products are formed during this reaction. The data collected using these methods indicates that the methanol decomposes to form a methoxy intermediate, which then rapidly dehydrogenates to form products of hydrogen and carbon monoxide. This insight greatly improves our knowledge of catalyst functionality for future applications.

Abstract Name: It's Only Politics, and What's That Got to Do With Us?: Cabaret and the Danger of Political Apathy

This paper examines the narrative of Cabaret in its entirety, analyzing its literary origins with the works of Christopher Isherwood, film adaptation at the hand of Bob Fosse, and multitude of theatre revivals (Isherwood, 1945, Kander, 1966). By utilizing an interpretive, comparative, and text-centered approach drawing from anthropology and cultural studies, each rendition of Cabaret is treated as a cultural artifact that reflects the socio-political ideologies of the people and the nations that are being represented. Specific characters in Cabaret, such as the Emcee, Clifford Bradshaw, and Sally Bowles, are used as individual case studies for the various ways in which people comprehend and cope with the rise of authoritarian fascism. In analyzing the story and the contexts in which it is being told the research argues that the novel/movie/play reveals the catastrophic consequences of political apathy both in Weimar Germany and in the modern day (Grey, 2024). This research analyzes the different character's responses to rising fascism in Germany in the late 1920s and early 1930s, and connects these responses to the contemporary politics of the United States. Specifically, the research examines how quickly the contested morals of political extremists in power become normalized, accepted, and eventually embraced by the citizens who once condemned them the second that those very people turn apathetic towards the injustices of rising fascism. As this apathy eventually results in the collapse of the Weimar Republic, this analysis offers a cautionary tale for the future of the U.S.

Abstract Name: Your Brain on Grades: Neural Sensitivity to Graded Academic Feedback

Feedback-related negativity (FRN) is a fronto-central event-related potential (ERP) that emerges approximately 200–300 ms after feedback and is commonly associated with detecting outcomes that deviate from expectations. This component is typically followed by a P3 waveform (300–400 ms), which has been linked to reward processing and exhibits a centro-parietal distribution. The present study examined FRN and P3 responses using a novel three-tiered feedback paradigm that expanded traditional correct/incorrect feedback to include a “critically incorrect” category modeled after academic evaluations. Undergraduate participants completed a time-estimation task in which they attempted to indicate when one second had elapsed. Feedback was provided based on degree of inaccuracy in the form of academic letter grades (A+, C+, or F). Task difficulty was adaptively adjusted to ensure exposure to a range of feedback outcomes. ERPs were analyzed from a fronto-central region of interest (ROI) combining Fz and FCz for the FRN, and a parieto-occipital ROI combining Pz and POz for the P3. Planned comparisons examined differences between correct (A+) and incorrect (C+ and F combined) feedback, as well as between incorrect (C+) and critically incorrect (F) feedback. Incorrect feedback elicited a more negative FRN than correct feedback at the fronto-central ROI, and critically incorrect feedback generated a significantly more negative FRN than incorrect feedback. At the parieto-occipital ROI, correct feedback demonstrated a larger P3 amplitude than incorrect feedback, while no difference was found between incorrect and critically incorrect outcomes. These findings suggest that the FRN tracks graded levels of feedback deviation, whereas the P3 may primarily distinguish positive from non-positive outcomes. Future research will investigate how expectations and individual differences, such as susceptibility to stereotype threat, modulate neural responses to graded feedback.

Abstract Name: Environmental Pollutants and Pathogen Behavior: The Role of Microplastics on *Batrachochytrium dendrobatidis*

Amphibian populations are declining due to multiple environmental stressors including pollution and infectious pathogens. The most devastating pathogen is *Batrachochytrium dendrobatidis* (Bd), a fungus that infects amphibian skin disrupting electrolyte balance and leading to cardiac arrest. Meanwhile, microplastics (plastics smaller than 5 millimeters) are widespread pollutants in water systems and biological tissues. Although microplastics are known to alter amphibian development and physiology, their effects on pathogens such as Bd remain poorly understood. This study investigates how microplastics influence Bd growth, gene expression, and virulence. Two common polymers, polyethylene and polystyrene, were introduced into two strains of Bd culture. Growth was quantified using hemocytometer counts and optical density measurements. Polyethylene increased zoospore production and fungal growth, whereas polystyrene had minimal impact. The fungus appears to integrate the microplastics into its biofilm-like structures as observed through Scanning Electron Microscopy. Microplastics may also alter Bd virulence. Virulence can be assessed through enzyme activity and adhesion proteins important for host infection. After culturing the zoospore and zoosporangium stages with the API ZYM test strips, zoospores produced more enzymes than zoosporangia cells in the presence of plastics, but plastics decreased enzyme production (8/16 enzymes decreased). After allowing zoospores time to adhere to skin-based molecules, neither plastic interfered with Bd attachment as measured with the XTT assay, but may provide a competitive location to attach. Gene expression analysis using qPCR and primers specific for enzymes and adhesion factors is being conducted to verify test results. Finally, growth of the fungus with plastics and amphotericin B revealed inherent resistance across strains regardless of microplastic exposure. Future work will test alternative antifungal agents and additional stress conditions. By integrating environmental biology and genetics, this research aims to clarify how pollution influences pathogen behavior, offering insight into the complex interplay between contaminants and disease that threatens amphibian survival.

Abstract Name: Development of a Nanoparticle-based Lateral Flow Assay for the Detection of Mercury in Drinking Water

Heavy metals have lived in the Earth's crust for millennia, but in more recent years their extraction has increased. Smartphone production has led to an increase in small-scale gold mining globally, which produces mercury pollution. Furthermore, burning fossil fuels has increased mercury pollution in the atmosphere. Through atmospheric deposition, mercury can fall into waterways through precipitation. Once in waterways, inorganic mercury salts can form (Hg^{2+}), which can be detrimental to human health. When ingested, Hg^{2+} can cause gastrointestinal effects such as vomiting and abdominal pain. The current EPA restrictions limit the concentration of mercury to 2 ppb for drinking water; however, water sources do not always meet this criterion. Testing for mercury is done with instrumentation such as inductively coupled plasma optical emission spectroscopy or cold vapor atomic absorbance spectroscopy, that are not available and/or affordable for many. Our goal is to create a simple inexpensive paper-based lateral flow assay (LFA) to make heavy metal testing accessible to the public. Lateral flow assays are rapid tests (5-30 mins) used to detect or quantify analytes. Each LFA has a control line, which ensures the test's functionality, and a test line(s), which indicates the presence of the analyte(s). In this work, a control line composed of pH sensitive nanoparticles is used. The control line consists of nanoparticles synthesized from Neutral Red, poly (styrene-co-maleic acid) (PSMA), and polyvinyl alcohol (PVA). The test line is composed of nanoparticles synthesized from Rhodamine B, poly (styrene-co-maleic acid) (PSMA), and polyvinyl alcohol (PVA). These nanoparticles were characterized by using Dynamic Light Scattering (DLS), to confirm nanoparticle formation, and UV-Vis spectroscopy, to verify a colorimetric response. After validation, nanoparticles were incorporated onto a nitrocellulose lateral flow strip. The sensitivity and specificity of the tests were optimized for future use as an affordable option for testing drinking water.

Abstract Name: Deep Learning-Driven Predictive Analytics Model Development for SQL Injection Detection in Cyber Space

SQL injection attacks remain one of the most critical threats to data security, often resulting in severe breaches and financial losses. Proactive detection of these attacks is essential for safeguarding database systems and reducing organizational risk. This research introduces an AI-driven predictive analysis model designed to identify SQL injection attempts before they compromise data integrity. To achieve this, a hybrid deep learning architecture is proposed that is combining one-dimensional Convolutional Neural Networks (1D CNN) and Recurrent Neural Networks (RNN). The proposed model has been implemented and tested on the Python platform. The model has trained on an open-source dataset that contains over 2,44,100 SQL queries for both injection and benign cases, ensuring comprehensive coverage of attack patterns. Local query patterns are captured through a 1D convolutional layer with max pooling, while sequence-dependent features are learned via a recurrent layer. Word embedding techniques further enhance the representation of SQL

statements, enabling the model to process structural and semantic information effectively. Evaluation results demonstrate strong performance, with a training accuracy of 92.31% and validation accuracy of 92.21%, alongside a validation loss of 0.1799 after five epochs. These outcomes confirm the model's ability to reliably distinguish between malicious and benign queries. Planned refinements, including hyperparameter tuning and architectural adjustments, aim to further improve accuracy and robustness. By enabling early detection of SQL injection attacks, this approach contributes to reducing data breach risks and strengthening overall cybersecurity resilience. Future work will focus on real-time deployment and extending the framework to other injection-based vulnerabilities.

Abstract Name: The Mediterranean Diet and Premature Birth: The Interplay Between Proinflammatory Cytokines and 11 β -Hydroxysteroid Dehydrogenase 2

With an aim to determine the mechanism by which the Mediterranean Diet (MD) decreases the risk of premature birth, this study examines the relationship between proinflammatory cytokines, 11 β -Hydroxysteroid Dehydrogenase 2 (11 β -HSD2), and cortisol. Adherence to the MD decreases both cortisol levels and the risk of premature birth, while high cortisol levels are linked to increased risk of premature birth. Increased levels of proinflammatory cytokines TNF- α , IL-1 β , and IL-6 inhibit 11 β -HSD2 activation, increasing fetal cortisol exposure and subsequently raising premature birth risk. The MD may lower increases in proinflammatory cytokines, therefore explaining how MD adherence lowers the risk of premature birth. A literature review was conducted to examine the correlation between the MD and proinflammatory cytokine levels. Flor-Aleman et al. found that TNF- α levels decreased at the 34th gestational week with higher MD adherence, while Ramon Estruch found that IL-6 levels decreased with MD adherence supplemented with mixed nuts and olive oil. Additionally, Koelman et al.'s systematic review of MD adherence revealed that TNF- α , IL-1 β , and IL-6 concentrations significantly decreased. Synthesis of these results suggests that the MD's ability to lower proinflammatory cytokines increases 11 β -HSD2 activation, thereby reducing fetal cortisol exposure and decreasing the risk of premature birth. Future research should analyze inflammatory cytokine concentrations in preterm births from mothers who did and did not follow the MD to test the validity of this conclusion.

Abstract Name: Background Studies of the Neutron Detector for the HIBEAM Program at the European Spallation Source.

The HIBEAM program at the European Spallation Source (ESS) aims to investigate baryon number-violating processes and other physics beyond the Standard Model using high-intensity cold neutron beams. As part of this effort, a dedicated neutron detector is being developed to provide precise beam monitoring and strong background suppression. In this work, we conduct a systematic study of the neutron and gamma backgrounds that reach the detector under different geometric and shielding configurations. By using Monte Carlo

simulations, we model how neutrons arrive at the detector from both the direct beam and from scattering on nearby components. The results show that the background distribution is highly sensitive to the surrounding materials. Changes in shielding and structural layout significantly affect flux distribution of background neutrons and gammas, with some configurations leading to increased scattered-neutron flux, while others more effectively suppress backgrounds and produce a cleaner signal. Overall, this work provides guidance for optimizing the detector design within the HIBEAM program by identifying the main contributors to the neutron and gamma backgrounds.

Abstract Name: Dante Alighieri's Search for Justice

In a society where justice had plural meanings, Dante Alighieri explored God's final realm of justice in his piece *The Inferno*. Since Dante wrote this piece in the Middle Ages, the injustices that he personally experienced as well as the perceived injustices of a whole society affects his view of biblical justice. This is shown in how he portrays hell and the eternal punishment that society believed awaited all of humanity. Dante experienced injustice at an early age when his lover, Beatrice, was married to another man. Dante continued to love her throughout his life even after her death and compared her to an angelic being in *The Inferno*. Dante further puts his spin on justice when he includes Maximus and Brutus in the lowest level of hell, equal with the Devil. This placement of the murderers of Julius Caesar shows how the Roman empire was interpreted by societies in a reverent way even hundreds of years after its fall. His interpretation of justice gives insight not only into his personal beliefs but also the beliefs of a whole culture. Dante's fictional story has become a critical part of understanding Medieval culture both in Dante's image of the world and the development of Medieval society after the publication of *The Inferno*; these injustices and their reflection on Medieval culture deserve to be studied.

Abstract Name: Linking Brain Structure with Epilepsy and Behavioral Measures in Chromosome 8p Rearrangements

This current project is being conducted in collaboration with the Project 8p Foundation, an initiative that aims to create the world's first MRI-based cortical surface and volumetric brain atlas for individuals with chromosomal 8p variations. Chromosome 8p rearrangements affect about 1 in 10,000 children and is associated with various neurodevelopmental disorders including epilepsy and developmental delays. Current neuroimaging studies lack accurate atlases to investigate 8p neuroanatomy, which is commonly characterized by enlarged ventricles and corpus callosum anomalies. This project aims to create an 8p brain template and atlas specific to this population. We also seek to link epilepsy and other behavioral measures to gray matter structure. In this study, pediatric MRIs of individuals with confirmed 8p rearrangements will be processed and corrected to assess gray matter volume in key regions of interest. The main focus is to examine brain-epilepsy relationships in neural regions of interest by correlating cortical thickness and gray matter volume

measures with seizure outcomes (presence/absence, severity, genetic markers, and age-of-onset), as about one-third of the cohort has epilepsy. We will compare brain structure measures in 8p individuals with various phenotypic and genotypic measures and identify the potential genetic and brain structure biomarkers correlated with epileptic occurrences. The expected aims of this study include creating the first MRI atlas for chromosomal 8p variations, identifying structural biomarkers linked to epilepsy severity, and discussing these findings in various journals and presentations, including the American Epilepsy Society meeting and the Project 8p Scientific Symposium.

Abstract Name: The Persistence of Memory and Modernity in Meiji Woodblock Prints

After a 200-year period of isolation, Japan opened its borders to international exchange in 1854. Emperor Meiji (1867–1912) established a directive to modernize Japan, take on Western culture, industrialize the landscape, and organize propaganda to initiate the restoration of imperial authority under his reign (r. 1867–1912). Woodblock artists like Kobayashi Kiyochika (1847–1915) and Toyohara Chikanobu (1838–1912) were born into samurai families stripped of their titles when the emperor assumed power, yet they interpret this moment in history differently. The novelty of new technology, like the gas lamp and railroads, excited people, but there was an underlying anxiety that traditional Japanese culture would be forgotten. This presentation will interrogate how Kobayashi Kiyochika and Toyohara Chikanobu represent the paradoxes at the heart of the Meiji period (1868–1912). In an art historical visual analysis of two exemplary works by the artists, this presentation will further claim that these artists could represent the mindsets of Japanese people, reflecting the tensions between Japan's anxiety around cultural preservation and the more assertive embracing of Western influence during the 1880s. Kiyochika's print *Fireworks at Ikenohata*, published in 1881, illustrates the nostalgia of Japanese culture during the Edo period (1603–1868), in a reflective moment of celebration where new technology is subverted by traditional candle lanterns and fireworks in the surrounding darkness. Chikanobu's print *Nobility in the Evening Cool*, published in 1887, embodies how Western modernization was an idealized directive for the Japanese Imperial court because of the use of Western dress, gas lamps illuminating the landscape, and modern architecture. This research underpins how national identity at this time in Japan is not monolithic because rapid modernization diverged the values of preserving cultural memory and embracing industrialization.

Abstract Name: Parents know best: The relationship between parenthood and children's co-ed sports

Adult men and women competing in the same sports doesn't sound fair, but what about children? During the early years of life, there is no significant difference between genders in terms of physical ability. Presumably, those who are parents/guardians have different outlooks on this controversy than those who are not. To better understand this controversy, a seventeen question survey was completed by 417 respondents. Analysis of the results showed that those that were parents and guardians were more likely to allow their children to

participate in co-ed sports than those that were not, with 49.8% of parents responding “yes, always” and 35.4% of parents responding “yes, but only at younger ages.” Hypothetically, those that do not have children are less comfortable with letting their children play sports with the opposite gender, which might suggest that parental experience creates a change in perspective. However, when respondents were asked whether they believe that children’s co-ed sports come with challenges such as differences in physical development most of them answered that they agreed (38.9% of respondents) or strongly agreed (29.7% of respondents). This could suggest that regardless of the acknowledged challenges of co-ed sports, parents and guardians still find value in children participating in co-ed sports.

Abstract Name: Trust and Safety in the Time of Algorithmic Amplification and Polarization

Algorithmic amplification is the internal mechanism that dictates the magnification of certain speech and the repression of other view points. In a time of ever increasing polarization with technology companies becoming more and more powerful, how do we achieve transparency within algorithms and algorithmic amplification while protecting proprietary information? How do we as a society best manage the wide reaching impacts of polarization due to algorithmic amplification in social media. Trust and Safety departments within online companies work to safeguard users from harm. They incorporate human oversight into the platform and produce transparency reports. Research surrounding Trust and Safety as well as regulation around the internet have so far not taken into account the boom of artificial intelligence and mass consumption of data. Policy and regulation surrounding speech online has not been updated significantly in this millennium. The the majority of recent regulation focused on child sexual abuse material (CSAM) and copy right issues. There is a lack of research on how AI and the ever increasing push for data will impact society, the power of tech companies and the ways in which they exert that power on government. The methodology is qualitative research working off previous research conducted as well as the interior Trust and Safety policies of the big five technology companies Microsoft, Apple, Alphabet (Google), Amazon and Meta. This project will address the role of polarization due to algorithm amplification and the role of transparency while highlighting the power of these industry super powers. A thorough review of how the key stakeholders government, industry, and the consumer interact in an environment of insufficient regulation.

Abstract Name: The effect of propylparaben on hsp70 expression during axolotl limb regeneration

Wound healing and regeneration have long captivated biologists as a viewpoint into the body’s ability to heal and rebuild. The axolotl (*Ambystoma mexicanum*) is an aquatic salamander known for its enhanced capacity to regenerate complex and fully functional tissues without scarring. Regeneration occurs through three coordinated stages: wound healing, blastema formation, and tissue differentiation, each driven by distinct patterns of gene expression. Among these genes, previous research indicates that hsp70, encoding heat shock

protein 70, is upregulated following exposure to stressful situations, such as limb loss. This molecular chaperone facilitates proper folding of newly synthesized polypeptides, a crucial process for rapidly dividing cells. However, the aquatic existence of axolotls exposes them to anthropogenic contaminants, including parabens, which are endocrine-disrupting chemicals frequently used as preservatives in consumer products. Propylparaben (PrP) is of particular concern because it is a longer-chain paraben which produces stronger estrogenic activity, reproductive toxicity, and eventually produces developmental abnormalities. Despite its prevalence, the biological effects of propylparaben remain insufficiently characterized, especially in regenerative species. This research explores the impact of propylparaben exposure on hsp70 expression during axolotl wound healing and tissue regeneration. Twenty-four axolotls were injected with one of three treatments (0% PrP saline control, 0.0014% PrP, 0.14% PrP) and subjected to two successive amputations for sample collection at Time 0 (non-regenerating tissue) and Time 72 (regenerating tissue). RNA from each tissue sample was isolated, purified, and reverse-transcribed to cDNA, followed by PCR amplification using primers targeting hsp70. Relative expression levels were assessed with agarose gel electrophoresis. We predicted that increasing propylparaben concentration will decrease hsp70 expression during axolotl wound healing and tissue regeneration. Findings from this research will enhance understanding of how environmental pollutants influence molecular mechanisms of regeneration and highlight the broader role of hsp70 as a conserved stress-response gene across eukaryotes.

Abstract Name: Does women's empowerment improve child welfare? New evidence from Cambodia

Women's empowerment in developing countries remains understudied, and in particular its impact on child welfare. I examine how women's intra-household bargaining power – proxied by women's land ownership, education, perception about justified wife-beating, and household decision-making – affects child welfare indicators. Using Demographic and Health Survey (DHS) data from Cambodia from 2000 to 2022, I estimate how women's empowerment affects child school enrollment status and child anthropometric health outcomes. I also explore whether these impacts differ by the gender of the child, and potentially reduce any gender-based inequality in child welfare. In order to reduce the bias in the estimators of these effects, I control for household level characteristics and region and time fixed effects. The findings will contribute to the literature on gender and development by providing new evidence from Cambodia and offering insights for policies targeting child welfare.

Abstract Name: Testing DRGN-1 Variant Peptides for Improved Antibacterial Activity

DRGN-1 is a synthetic peptide derived from a Komodo-dragon histone H1 fragment (VK25) that has demonstrated antimicrobial, antibiofilm, and wound-healing properties in vitro and in vivo (Chung et al., 2017). However, its antibacterial activity was primarily observed under low-salt EC₅₀ conditions and was substantially reduced under mammalian physiological ionic environments used for MIC testing (Chung et al.,

2017). Additionally, potency varied across bacterial species, with *Staphylococcus aureus* requiring higher effective concentrations than *Pseudomonas aeruginosa* (Strain 9027). These limitations motivated the development of DRGN-1 peptide variants with the hope for improved activity against clinically relevant wound pathogens. In this ongoing project, a panel of rationally modified peptides incorporating amino acid substitutions to increase charge, hydrophobicity, or structural stability is being evaluated. This project evaluates rationally modified peptides incorporating amino acid substitutions to enhance charge, hydrophobicity, and structural stability. Antimicrobial screening in low salt buffer (EC₅₀) against *S. aureus* ATCC 25923 (SA25923) was performed using 96-well microplate assays and analyzed in GraphPad Prism. Preliminary results show that the triple-arginine variant DRGN-1R1R7R10 exhibited enhanced potency with an EC₅₀ of 3.49 µg/mL compared to the parent peptide, while several single-site mutants showed much less activity. The parent peptide did not reach an EC₅₀ within the tested concentration range under these assay conditions, suggesting reduced apparent activity compared with earlier reports. Interestingly, variants containing fewer arginine substitutions or alternative designs, such as R1R7 and RW peptides, demonstrated moderate improvements but lower overall potency than the triple-arginine construct. Ongoing work focuses on assessing the minimum inhibitory concentration (in physiological salt conditions) and antibiofilm activity using crystal violet–based assays for top variants to identify lead peptides with improved potency and therapeutic potential for wound infection treatment.

Abstract Name: Beyond the Skin: The Emotional and Social Burden of Acne in Youth

1. Central Research Question and Purpose of the Project Acne is one of the most common dermatological conditions among adolescents and young adults, yet its emotional impact is often overlooked. This project asks: How do acne and acne scarring influence emotional well-being, social interactions, and identity development in teens and young adults? The purpose of this review is to summarize recent findings on the psychological and social effects of acne during a critical developmental stage. 2. Scholarly Context and Contribution Growing awareness of youth mental health and intensified social media pressures have increased interest in how appearance-related conditions affect psychological outcomes. While existing studies examine issues such as self-esteem or anxiety independently, few provide a comprehensive synthesis. This review contributes an updated, integrated analysis of research from 2015 to 2025, highlighting how acne interacts with self-image, emotional distress, and social experiences in today's media-driven environment. 3. Research Methodology This project uses a qualitative literature review approach. Fifteen peer-reviewed studies published between 2015 and 2025 were selected based on their focus on adolescents or young adults and their examination of at least one psychological variable, including self-esteem, anxiety, depression, or quality of life. Common themes were identified through comparative analysis. 4. Conclusions and Expected Results Three major conclusions emerge: (1) acne is associated with lower self-esteem and increased social anxiety; (2) acne scarring causes long-lasting emotional distress; and (3) social media exposure intensifies negative body image through comparison and idealized imagery. These findings support the need for dermatological care that incorporates mental-health support. Future research should explore long-term emotional recovery and the role of supportive environments in improving outcomes.

Abstract Name: The Search for Relief: How Physical Therapy Interventions Play a Role in Chronic Pain Management

Chronic pain is a pervasive condition that significantly impairs a person's functional abilities, quality of life, and emotional well-being. Historically, opioid medications were among the most common forms of treatment for chronic pain, however, this approach has become increasingly scrutinized over time due to concerns regarding limited long-term effectiveness, dependency, and other associated harms. In response to these challenges, physical therapy has emerged as a critical non-pharmacological strategy for long-term pain management, offering a holistic and patient-centered alternative that emphasizes movement, education, and active participation in care. To better understand the intersection between chronic pain relief and physical therapy interventions, this project will conduct an in-depth literature review of scholarly sources that examine how physical therapy supports sustained pain reduction and improved daily functioning. This process will involve searching relevant academic databases to identify peer-reviewed research that explores the clinical applications and outcomes associated with physical therapy in chronic pain management. By synthesizing findings across diverse studies, the project aims to highlight common themes, identify effective therapeutic approaches, and assess the overall impact of physical therapy within interdisciplinary care settings. Central to our investigation is an exploration of how physical therapy contributes to improved function, enhanced self-efficacy, and greater autonomy among individuals living with chronic pain. We will examine how physical therapy supports patients in understanding the nature of their pain, reducing maladaptive responses, and developing practical, sustainable self-management strategies. Through this analysis, we aim to clarify the unique contributions of physical therapists in chronic pain management and to identify key principles that support long-term, non-pharmacological relief. Ultimately, this project seeks to deepen understanding of how physical therapy can serve as an essential component in the comprehensive and holistic management of chronic pain.

Abstract Name: Detecting Regimes in Atmospheric Models

Atmospheric models of the climate are naturally chaotic, but meteorologists have conjectured that each can be clustered into smaller, more predictable regions called regimes. These regimes have been correlated with intraseasonal weather patterns. By using various algorithms to assess data from the climate, clusters will be found that can help predict future weather patterns. To prepare for the analysis of larger data from existing weather, 4 sets of data were used: Lorenz 63, Lorenz 96, Charney DeVore, and Jet Latitude. The first three datasets are simulations that cleanly represent real-world data while Jet Latitude is data taken directly from jet streams over the Atlantic Ocean. Climate data can be difficult to process due to the sheer number of data points; however, we lower its resolution by localizing nearby points onto a grid. This is known as "binning" or "coarse graining". Because these models are from well-understood equations, it is easy to check if a clustering algorithm is working as intended or not. After testing many algorithms, the Louvain Community Detection, Infomap, and Spectral Clustering yielded the most optimal results. Louvain Community Detection prioritizes the modularity of our binning graph; Infomap takes a "random surf" of the graph—a variant of a random walk but with an added "teleportation chance" variable; and Spectral Clustering looks at eigenvectors of the graph. By understanding these algorithms, each one offers an alternative regime of the same climate

data. After deciding on the best algorithms, we applied those algorithms to more datasets from our climate to cluster the models in hope of a better understanding of these global regimes. We posit that these results will help in predicting the effects of climate change and future movement of air currents worldwide.

Abstract Name: Deterrence by Architecture in the Lunar Regime: Establishing a Permanent Human Presence to Preempt Exclusionary Norms

The coming decade of lunar activity will establish technical and political precedents that will prove exceptionally difficult to reverse. Early choices in infrastructure, operational practices, and governance frameworks will create powerful path dependencies, locking in norms that will dictate the future of lunar commerce, science, and security. This paper evaluates three competing architectures for shaping this normative landscape: a robotics-only approach, episodic crewed missions, and a sustained human presence. It argues that a sustained, government-led, and commercially-integrated human presence offers the most effective mechanism for entrenching norms of openness, transparency, and interoperability. By analyzing historical precedents like the Antarctic Treaty System (ATS) and the International Space Station (ISS), and examining current strategies including the Artemis Accords and NASA's commercialization plans, this research demonstrates that continuous human operations generate unparalleled political salience, operational entanglement, and commercial scaling necessary for robust norm formation. The paper concludes by detailing a strategic path dependency for the United States, transitioning from the ISS to commercial LEO stations, and from a foundational government-led lunar base to a thriving commercial lunar ecosystem, thereby cementing an open, rules-based order on the Moon.

Abstract Name: Invisible in Plain Sight

This qualitative case study explores the classroom perceptions and lived experiences of Latinx undergraduate students enrolled at a Predominantly White Institution (PWI). Drawing from two focus groups with five participants total, the study employs thematic analysis to examine how students navigate academic spaces shaped by whiteness, cultural invisibility, and performative diversity. Five interrelated themes emerged: classroom engagement and participation anxiety, representation and curriculum gaps, relational pedagogy and inclusive teaching, peer dynamics and social exclusion, and structural and institutional barriers. Findings reveal that relational pedagogy, defined by bell hooks (1994) as the practice of teaching "to transgress" through care and connection, plays a central role in fostering belonging. Students described feeling more engaged when professors acknowledged their lived realities and practiced inclusive dialogue, aligning with Gay's (2018) framework of culturally responsive teaching. Conversely, classrooms dominated by lecture or Eurocentric content reinforced feelings of isolation and conditional visibility, echoing Yosso's (2005) critique

of deficit perspectives in higher education. Participants also noted that course materials often reflected a persistent Black–White racial binary that rendered Latine identity “invisible in plain sight,” consistent with findings by García and Johnston-Guerrero (2015) on Latinx identity negotiation at PWIs. This study contributes to a growing body of scholarship on inclusive pedagogy and belonging by highlighting the emotional labor and cultural taxation (Padilla 1994) that Latinx students experience when their identities are underrepresented or misrepresented in academic spaces. The findings underscore the need for faculty development grounded in cultural humility, curricular diversification that integrates Latinx epistemologies, and institutional accountability that moves beyond symbolic diversity efforts toward transformative inclusion. Keywords: Latinx students; higher education; inclusive pedagogy; representation; belonging; Predominantly White Institutions

Abstract Name: Analysis of Conserved Domains in Promoters of Differentially Expressed Genes in Rice

Plant responses to stress involve changes in gene expression, and understanding these changes is key to improving crop resilience. A critical step in this process is identifying "conserved domains" in the promoters of Differentially Expressed Genes (DEGs), as these domains often provide binding sites for transcription factors. In this study, we aim to identify the Cis-Regulatory Elements (CREs) in the promoters of DEGs associated with heat stress. Previously, we identified 149 DEGs from transcriptomic analyses of two rice varieties, Cypress (heat-tolerant) and LaGrue (heat-sensitive), both exposed to high night temperatures (HNT; $82.4 \pm 1^\circ\text{F}$ or $28 \pm 1^\circ\text{C}$). We hypothesize that the DEGs, either up- or down-regulated under HNT stress, may share a set of common CREs or exhibit specific polymorphic patterns that correlate with distinct DEG expression patterns. To test this hypothesis, we analyzed the promoter sequences using two bioinformatics tools—‘ElemeNT’ and ‘MEME’—to identify core promoter motifs, their relative positions to the Transcription Start Site (TSS), and their statistical significance. These motifs were functionally annotated, revealing potential roles in the regulation of stress-responsive genes. The annotation indicated that certain motifs are enriched in promoters of up-regulated genes, while others are associated with down-regulated genes under heat stress. These findings will be further examined to determine how variations in these CREs correlate with gene expression patterns during heat stress.

Abstract Name: Meaningful EngAGement in Dementia Care: Memory Books

This study aims to enhance targeted clinical skills of undergraduate students majoring in Communication Sciences and Disorders (CSD) in dementia care via creating a dementia friendly program. Six student researchers designed a series of strengths-based Memory Books for popular Montessori-based activities and implemented the program with individuals with dementia. Montessori-based activities centered the five senses to create active social engagement, productive conversation, and meaningful enjoyment for individuals with dementia, despite their cognitive deficits (Hindt, Morris, Sohre, & Buchanan, 2018; Jarrot, Gozali, & Gigliotti, 2008). In this study, students created Memory Books that correlate to three Montessori activities (Sensory Station, Flower Arrangement and Toolbox) which include themed-based pictures, short stories, descriptions, Would You Rather questions, and tactile materials as conversational topics with visual and auditory contextual support. Research participants were 20 undergraduate students majoring in CSD. They learned to conduct ten 50-minute one on one or small group sessions in a long-term care facility for six weeks. They observed and documented a variety of engagement types (e.g., positive, negative, no engagement) and frequency using a 5-point rating scale and conversational transcript during each session. They conducted a self-rating on their perception of dementia and their clinical skills prior to and after each session. The research project is ongoing, and the program outcome is currently obtained through qualitative and quantitative measures. This research project offers future healthcare professionals a strengths-based, person-centered framework to engage meaningfully with individuals living with dementia, enhancing their understanding of the diagnosis and ability to provide dementia friendly care.

Abstract Name: Threads of Control: Gender, Power, and the Spider in Greek and Japanese Mythology

Spiders are studied in this research as a cross-cultural symbol in art history. This study argues that both archaic Athens and the early nineteenth-century Edo-period Japanese cultures used the spider as a symbol to reinforce patriarchal ideologies, portraying women's independence and sexuality as dangerous forces that threaten male authority. In the first section, this research will examine the duality of the symbolism of spiders, emphasizing its positive and negative traits, such as a master weaver or a trickster. The second section will provide a brief history and culture of archaic Athens, highlighting negative social attitudes toward women. In the third section, the study will investigate the myth of Arachne who was turned into a spider for her excessive pride and challenging authority. The fourth section demonstrates that nineteenth-century Edo was similarly misogynistic and patriarchal. In the fifth section, to illustrate the devaluation of the Edo women, the story of the mythological creature Jorō-gumo is provided. The comparative conclusion emphasizes that the symbol of the spider reflects the cultural perceptions of femininity, although within different social frameworks, in order to reinforce patriarchal attitudes and maintain control over women.

Abstract Name: A Study in Resin

My research yielded a new approach to working with UV resin. My idea first came from a desire to make

plants permanent, since mine weren't doing so well. I knew that I wanted to create a work of art that played off of the light, which led me to research stained glass artists whose subjects were plants. Because of limitations, I decided to work with a clear resin that cured using UV light. After much trial and error, I found a unique way of using jewelry wire as a frame for the leaves of plants. I experimented with methods of changing the color of the resin, and found an interesting interplay between acrylic paint and the UV resin. My greatest discovery came from the manipulation of the leaves to create organic shapes. UV resin is usually poured into a mold and cured. I found a way to spread the tinted resin thinly on a silicone mat, partially cure it, and then bend it into its final shape. Having researched this extensively, I found that this is an original use of the medium, finding no examples of similar work. For this reason, I formed a presentation that serves as a demonstration of my research process, but also as a guide for fellow artists and educators to mirror this new technique.

Abstract Name: How drug-resistant bacteria persist on hospital or public surfaces and how cleaning methods affect them

Healthcare facilities contain many high touch surfaces, such as door handles, desks, bed rails, and bathroom fixtures. These areas are touched frequently and can function as reservoirs that support bacterial spread. This increases the likelihood of healthcare associated infections, in which patients acquire a secondary infection during their hospital stay. Surgical instruments and other operation related tools can also transmit bacteria when cleaning or sterilization is inadequate, and these infections can worsen illness, prolong recovery, and complicate treatment. A significant concern is the presence of bacteria that are resistant to commonly used antibiotics. These organisms can persist on both environmental surfaces and medical tools and are associated with infections that are difficult to treat and control. Understanding their distribution and how effectively they can be removed is essential for improving infection prevention. This project investigates bacterial contamination on frequently touched surfaces and examines whether antimicrobial resistant strains are present. It also evaluates how effective common cleaning and disinfecting methods are at reducing bacterial levels. The goals are to identify the surfaces with the highest bacterial load, determine whether resistant strains persist longer than non resistant strains, and assess which cleaners provide the greatest reduction. To measure contamination, we will swab selected surfaces before and after cleaning. One swab will be streaked onto nutrient agar to count total bacteria, and another will be streaked onto nutrient agar containing antibiotic to detect resistant bacteria. After cleaning with standard alcohol based or bleach based wipes, the same areas will be swabbed again. Plates will be incubated at about 30 degrees Celsius for 24 to 48 hours, and colony forming units will be counted or scored. Finally, we will compare bacterial levels before and after cleaning and calculate percent reductions. Bar graphs will also be used to highlight differences among surfaces and cleaning products.

Abstract Name: Computing The GPV Theorem

In mathematics, a knot is a closed curve in 3-dimensional space with no self-intersections. From a topological perspective, knots are made of thin and flexible material; if you bend, stretch, or rearrange a knot without cutting, a topologist would say it is the same knot. A link is made up of two or more knotted components that intertwine. The field of knot theory centers on classifying knots and links by their defining characteristics. The main tools used to distinguish knots and links from each other are called invariants. There are hundreds of different invariants, one such example is the minimal crossing number of a knot or link. There is a special class of invariants called finite-type invariants that satisfy a crossing change property. The GPV theorem states that all finite-type invariants can be computed by a two-step process. Regardless of which finite type invariant you start with, the first step is always exactly the same step. This theorem provides a uniform way to compute all finite-type knot invariants in a very computationally efficient manner that can be easily programmed into a computer. We wrote a python program to automate the first step of the GPV theorem. The main question of our research is to compute the second step of the GPV theorem, which is dependent on the particular knot invariant you apply the theorem to. We are focusing on the linking-number invariant and the quadratic coefficient of the Conway polynomial invariant. Our methodology is to use linear algebra techniques to compute the second step for these two invariants. The second step is a linear transformation on a vector space of diagrams. We are working to construct the linear transformation by computing individual outputs on a basis.

Abstract Name: Pilot Study: Multijoint Kinematic Analysis of Nursing Student Posture Using OpenCap in a Realistic Nursing Environment.

Musculoskeletal injuries, specifically those that present with lower back pain, are prevalent work-related musculoskeletal disorders among nurses and caregivers. These injuries are often caused by poor body mechanics during patient handling tasks. While proper posture is known to reduce the risk of injury, objectively assessing these movements in realistic environments remains difficult. Existing studies often focus narrowly on trunk flexion within artificial biomechanics laboratories, neglecting both multijoint coordination and the environmental constraints of actual clinical settings. This pilot study addresses these gaps by using OpenCap, a novel markerless motion capture system, to analyze nursing students' movement in a realistic nursing skills laboratory. Three participants performed a series of manual patient-handling tasks using manikins on a standard height-adjustable nursing bed and wheelchair. To simulate the change from "good" to "poor" posture, bed heights were incrementally lowered to alter body mechanics. For wheelchair lifts, posture was differentiated by the degree of knee flexion used. The primary objective was to validate a workflow for capturing complex trunk, hip, and knee flexion angles in the students' natural training environment. Preliminary trends observed in the data suggest an inverse relationship between bed height and joint angles; as bed height decreased, flexion in trunk, hips, and knees appeared to increase, consistent with "poor" posture definitions. In wheelchair trials, "good" posture was distinguishable by increased knee flexion, though trunk variability remained inconsistent. While statistical analysis is ongoing to confirm these patterns, the successful data collection validates the method. Ultimately, this project confirms that markerless motion capture is a viable tool for assessing complex, multijoint movements in realistic nursing environments.

Abstract Name: Success Beyond the Syllabus: Examining the Hidden Curriculum in Business Education

Despite advances in education, research continues to challenge the formal university curriculum and its inadequate formation of well-balanced, fully prepared students (Borges et al., 2017, p. 160). Business students are falling short of the expectations required for success in higher education. A key contributor to this issue is the hidden curriculum, an aspect of learning that is often overlooked and unacknowledged by business students. The hidden curriculum encompasses the untaught aspects of the educational experience, such as communicating with faculty, time management, preparedness for class, as well as the implicit norms, knowledge, and behaviors necessary for success. When these components go unrecognized, students may struggle within their degree programs and later in their careers, as essential aspects of their education remain underdeveloped. Higher education aims to prepare students for success both in the classroom and in their professional careers after graduation. However, research suggests that every learning experience contains explicit and implicit objectives, and these two dimensions can sometimes conflict (Orón Semper & Blasco, 2018, p. 485). While business schools communicate formal objectives, the lack of alignment between explicit expectations and implicit demands present ongoing challenges. Due to lack of research in this area, the purpose of this study is to understand which hidden knowledge, skills, and abilities business school students perceive as necessary for success, and to identify where gaps in awareness and application occur. Through comprehensive analysis of students' responses, this study seeks to uncover where business schools and students fail to connect explicit expectations with unspoken ones. Data will be collected through a Qualtrics survey, employing both quantitative and qualitative methods. The findings are intended to support faculty, administration, and other higher education professionals to better address the full spectrum of student learning needs and foster success beyond the syllabus.

Abstract Name: Investigating the Effect of Tyrosine Phosphorylation on SH2 Domain Binding

Src Homology 2 (SH2) domains bind to phosphotyrosines, making them critical in phosphotyrosine-mediated signaling. Based on CoDIAC (Kandoor et. al, 2024), we identified 3 SH2 domains (Lyn, Syk, and PTPN11) with 2 conserved phosphotyrosine sites each, located in the specificity determining region or binding pocket of the domains. Thus, we hypothesized that phosphorylation would alter or prevent substrate binding. The aim of this project is to determine the role of tyrosine phosphorylation on SH2 domain function and regulation. First, each tyrosine of interest was mutated to glutamic acid (E), the amino acid most similar to a phosphotyrosine. To determine the binding ability of these SH2 phosphomimics to phosphopeptides, overlay assays were performed, and software was used to determine binding intensity. This study indicated that phosphomimic mutations reduced binding to substrates compared to wild-type. We hypothesized that native phosphorylation would have an equal or greater effect on SH2-substrate binding. We generated mutant SH2 domains that allow us to study site-specific phosphorylation by mutating all but one tyrosine to phenylalanine

(F). Phenylalanine is the closest in structure to a tyrosine and cannot be phosphorylated, so we expect that these mutations will have minimal effects on binding, allowing us to isolate specific tyrosines for study without compromising function. WT and mutant SH2 domains were phosphorylated using our lab's kinase toolkit, which allows us to generate phosphoprotein through co-expression of a kinase and substrate in E.coli. We verified phosphorylation via Native PAGE before proceeding with overlay assays, allowing us to compare the WT and pSH2 binding profiles. Determining the effect of site-specific phosphorylation on binding allows us to understand how PTMs affect a domain's ability to bind to target sequences and signaling molecules. This knowledge aids us in further understanding the role of tyrosine phosphorylation when SH2 domains are dysregulated in disease.

Abstract Name: Every Drop Counts

I believe in the tool of graphic design to still be used as a means of creative expression and communication. In my own personal work, it is vital to create what I am passionate about. Growing up surrounded by Boston and NYC, cities with well-integrated public transportation, and growing up in an age of increasing awareness towards climate change, America's car dependent infrastructure has always been a subject in my life that I have wanted to spread more awareness towards with my art. The Graphic Design II class's 'visual voice' project became the perfect vessel for illustrating these problems in a single composition: arranging information to highlight the emotional weight of the subject. The design philosophy was to build something that established an immediate danger but still could be aesthetically humanist and optimistic towards finding better solutions-much in line with how we as thinkers and as artists can do our part in widespread issues. Compiling information from a variety of sources; news articles discussing corporate lobbying against high-speed rail, US Dept. Of Transportation and NHTSA web pages about roadway safety, and ecology research papers on air pollution's effects on the environment, I chose to represent the current car culture as contaminated and non-renewable. I used a blaring red, overarching gas pump, composed of the same overwhelming and harmful information I found in my research, and displayed it over a foggy blue background. In my eyes, a better and more healthy solution IS possible, but may only be achieved if we hold direct accountability to industries that are corporate lobbying against a safer future, and if we recognize the immediate issues, we face firsthand. Until then, we march further into a grey future for our environment.

Abstract Name: Evaluation of Reactive Oxygen Species production (ROS) production under copper stress in duckweed plants

Plants face several stresses in open environment and so is true for aquatic plants where chemical runoff is a common practice increasing the water pollution. These runoffs include salt, heavy metals etc. These pose a health hazard to plant and animals' life in the aquatic systems. This study evaluates the impact of copper-induced stress on an aquatic plant duckweed (*Spirodela polyrhiza*) with a focus on evaluating physiological and biochemical changes. Our results indicate that copper adversely impacts duckweed growth physiology in a concentrations dependent manner. Duckweed exposed to a range of copper concentrations (0–30 μM) for over 14 days period indicate reduction in clonal propagation and root growth with a significant difference after 10 μM and a complete lethality at/over 30 μM concentrations. Microscopic evaluation reveals that the incremental copper stress decreases the growth rate of duckweeds and impedes dissociation of daughter fronds from mother plants. Biochemical changes assessed for reactive oxygen species (ROS) detection for hydrogen peroxide with 3,3-diaminobenzidine (DAB) staining, indicated incremental production of hydrogen peroxide with increasing copper concentrations. Overall findings show that increased reactive oxygen species (ROS) production increases the oxidative stress possibly leading to cell death and suppressed growth changes.

Abstract Name: Satb2 Nuclear Import is Driven by an N-terminal Nuclear Localization Sequence

Satb2 plays a crucial role in regulating gene expression through chromatin organization. It is involved in a variety of processes including osteogenesis where it stimulates expression of the RUNX2 transcription factor. It is also widely used as a highly specific marker for colorectal cancer, and its nuclear absence is strongly associated with a worse prognosis. Nuclear proteins like Satb2 tend to rely on short amino acid sequences called Nuclear Localization Sequences (NLS) to direct their import into the nucleus. Satb2 has a predicted NLS located between amino acids 613-616. However, the functionality of the region has never been established. Using truncation analysis of EGFP-tagged Satb2, we tested which region is necessary for nuclear import. We then took 20 amino acid long segments of this region and individually attached them to a fluorescently-tagged cytoplasmic protein to see which region is sufficient for nuclear import of a cargo protein. Fluorescence microscopy reveals that Satb2 does have an NLS, but it is unexpectedly located in the protein's N-terminus, between amino acids 21-40.

Abstract Name: Inclusive Residential Design for Individuals with Non-Paraneoplastic Autoimmune Retinopathy

As the number of Americans experiencing visual impairment continues to grow, there is a need for housing that goes beyond basic accessibility compliance and instead anticipates sensory changes while maintaining comfort, dignity, and aesthetic character. Research shows that many existing homes lack adequate lighting, spatial clarity, contrast, and intuitive way finding, which can increase stress, risk of injury, and dependence on others. To address this gap, this study applies a research based design process, case studies of existing housing solutions, literature review on low-vision best practices, and site analysis. This research explores how residential interior design can better support independence, safety, and daily living for individuals with progressive visual impairments through intentional material selection, spatial organization, and technological integration. The project focuses on a single-family home designed for an individual with Non-Paraneoplastic Autoimmune Retinopathy (npAIR), a condition that gradually reduces functional vision. Research findings guided the development of a design strategy that uses layered lighting, contrast-based detailing, tactile way finding, and smart home technology to create an environment that supports both current and future visual needs. Natural materials, high contrast, intuitive circulation patterns, and voice-activated systems reinforce safety and familiarity while preserving atmosphere and residential character. The expected outcome is a design prototype proving that accessible housing does not need to feel clinical or utilitarian, but can instead express mood, nature, and personal identity while remaining functional and inclusive. This work contributes to ongoing conversations surrounding inclusive residential design by emphasizing the role of sensory-supported interiors in improving long-term quality of life for people with vision impairments.

Abstract Name: Provenance in the Book Lab Library

For my Distinguished English Major project, I am designing and implementing a catalog of the books in the Book Lab (VCU Campus, Hibbs Hall, room 408). This consists of three major components. One, I am compiling a digital catalog of the collection, which includes the book title, author, editor(s), Library of Congress call number, and provenance (in other words, previous owners and users). Two, I am adding corresponding physical cards to each book. Both the digital catalog and the cards include all of the information previously stated. The third component provides research into the provenance of the Book Lab collection. Using David Pearson's Books as History, I am writing biographies on a selection of the previous owners of the books in the Book Lab Library. The culmination of these components is a digital catalog, shelf marks, and biographies of the prior owners and users of the Book Lab collection.

Abstract Name: Geochemical Controls on Glauconite Variability and Heavy-Metal Enrichment in the Piney Point Formation, Virginia Coastal Plain

The Piney Point Formation of the Virginia Coastal Plain comprises glauconite-rich, fossiliferous sands whose mineralogical and geochemical variability provide critical constraints on glauconite formation processes and sedimentary conditions. This study examines the textural, mineralogical (XRD), and geochemical signatures of glauconite within a ~18 ft exposure along the Pamunkey River to evaluate vertical variations in glauconitization and to distinguish authigenic from reworked components. Bulk sediments were analyzed for grain-size distribution, and glauconite pellets were isolated from discrete sand-size fractions and characterized using X-ray fluorescence (XRF) and X-ray diffraction (XRD). XRD results confirm that the sediments are dominated by glauconite, quartz, and subordinate clay minerals, with glauconite showing variable crystallinity and broadened 10 Å basal reflections indicative of mixed-phase, evolving glauconitic smectite and more mature, well-ordered glauconite. This mineralogical heterogeneity parallels the textural and chemical variations observed in the section. Glauconite constitutes ~7–28 wt% of the bulk sediments (average ~17 wt%), increases systematically toward finer sand fractions, and disappears entirely from the >500 µm class, reflecting grain-size controls on glauconitization. Bulk XRF analyses show Ca, Si, and Fe account for ~90 wt% of the sediments, and intervals of reduced Ca–Si coincide with higher Fe and elevated glauconite abundance; trace metals (Ti, Cr, As, Hg, Pb, S) broadly track Fe-rich, glauconite-rich horizons. Collectively, the XRD mineralogy, geochemical trends, and textural data indicate that Piney Point glauconite formed predominantly in situ through progressive evolution from smectitic precursors under reducing, low-sedimentation, shallow-marine conditions, with minor reworking and mixing near the Piney Point–Old Church contact. These findings highlight glauconite as both a sensitive recorder of sedimentation rate and redox conditions and a significant geochemical sink for heavy metals in the Virginia Coastal Plain.

Abstract Name: Explorations of Border-Crossing Identity through Dreamscape in Frontera

This analysis examines how *Frontera*, a graphic novel that follows a young man as he attempts to cross the Sonoran Desert to return to Arizona after being deported, draws upon the mythologically-rich space of the desert to create a dreamscape that explores Mexican-American identity. Featuring visual differentiation, cultural icons, and spiritual figures that interact with the main character, Mateo, the text's dreamscape serves as a narrative bridge for characters to transcend their individual identity and connect with a communal identity. Specifically, the symbology of the American flag, a spiritual jaguar from Aztec mythology, and the ghost of an immigrant who died crossing the desert help Mateo reconcile with his evolving Mexican-American identity and sense of community. This research draws on the work of comics scholar Mark Di Paolo, who conceives of comics as a cultural marker of American identity that reacts to the social environment of the time, and Latinx comics scholar Frederick Luis Aldama, whose research highlights the rise in well-developed and complex depictions of Latinx identity in comics in recent decades. Read in conjunction with these scholarly perspectives, *Frontera* may be understood to react to a contemporary society in which the modern political environment threatens the deeply felt American identities of undocumented immigrants. By using dreamscape to explore Mateo's shifting identity throughout his deportation and border-crossing, and showcasing a variety of trans-cultural identities through the dreamscape's spiritual figures, *Frontera* depicts an interconnected, multi-cultural identity for both the main character and contemporary U.S. society.

Abstract Name: Decadal Soil Respiration Following Field-Simulated Insect Infestation and Ice Influence

Soil respiration (Rs) is the largest terrestrial carbon (C) efflux and plays a critical role in regulating ecosystem carbon balance. As Rs is highly sensitive to disturbances, understanding how it responds to increasingly common compound disturbances is essential. The long-term effects of these disturbances are poorly understood. In this study, we investigated how Rs changes over time in a temperate forest recovering from an experimental girdling treatment, followed by a naturally occurring severe ice storm eight years later. Our primary objective was to quantify interannual variability in Rs over eight years across a range of disturbance treatments, and evaluate whether the subsequent ice storm influenced Rs patterns by interacting with the simulated disturbance. This research was conducted as part of the Forest Resilience Threshold Experiment (FoRTE), in which girdling treatments were applied across distinct forested landscape ecosystems to simulate wood-boring insect infestation. Upper canopy trees were randomly selected, stratified, and girdled to simulate varying levels of canopy defoliation (0%, 45%, 65%, and 85%) and targeted canopy stratum (upper versus lower). Prior analyses revealed that Rs declined for three years following the simulated insect disturbance, with reductions directly proportional to defoliation severity, driven largely by tree and root mortality. A gradual recovery followed, consistent with ecosystem reorganization. We expect that an influx of fine woody debris following the ice storm will contribute to Rs recovery. Consequently, we anticipate that compound disturbance from ice will have comparable effects on Rs resilience across the disturbance severity gradient. This work provides insights into how compound biophysical disturbances change Rs over time. The results from this study are crucial for improving predictions of forest C balancing in response to increasingly frequent insect outbreaks and climate-related extreme weather events.

Abstract Name: Who Are We to You, and What Does That Make Us?: A Qualitative Study on the Role of Digital Media in Shaping Diasporic Perceptions

Over the past two years, digital media has played a significant role in shaping how information about the ongoing genocide in Palestine is accessed, interpreted, and shared, particularly in Western contexts. For members of the Palestinian diaspora community, the role of digital media and the discourses, news, and content it hosts, serves as a key influence in constructing their perceptions of the crisis in Palestine. This study is guided by a critical media/cultural studies framework, which examines the interconnectedness of media and culture in shaping identities, social structures, and power dynamics (Hammer & Kellner, 2009; Kellner & Storay, 2009). Eight participants that self-identified as being a part of the Palestinian diaspora community participated in individual, qualitative, semi-structured interviews that focused on assessing the role of digital media in shaping this community's perspectives of the ongoing genocide. A

thematic analysis of interview transcripts was conducted, identifying four overarching themes: (1) The Genocide Debate, (2) Perceptions Shaping Genocide Perception, (3) Sources of Information Currently Shaping Genocide Perceptions, and (4) Genocide Perception & Identity Impact. Themes were included alongside subthemes to further reflect the complexity of participants' responses. The findings suggest that although digital media was not shown to directly construct this community's perceptions of the genocide, it served as a critical tool for informing those perceptions through access to alternative narratives, fact-checking, and cultural memory. Additionally, digital media fostered identity affirmation, collective reflection, and resistance against cultural erasure. The findings in this study advance broader discussions within the field of communications surrounding the role of digital media in shaping collective understanding and perception within marginalized, diasporic communities, and the role of digital media in informing perceptions of significant international developments.

Abstract Name: Effects of Body Composition on the Energy Cost of Treadmill Walking

Walking is a common form of exercise that has been shown to provide numerous health-related benefits including lowering blood pressure and reducing cardiovascular disease risk. Additionally, walking contributes to daily energy expenditure and can therefore contribute to improve energy balance. Investigating factors that influence energy expenditure during walking can improve our understanding of the bioenergetics of movement and improve our ability to develop effective exercise prescriptions. Data published on the effect of body composition on the metabolic cost of walking (MCOW) has been inconsistent depending on the population studied and the walking speeds investigated. Therefore, the purpose of this study is to evaluate the effects of body composition on the gross and net MCOW in young adults at three different treadmill speed/grade combinations. Apparently-healthy adults (N=40) between 18-30 yrs are being recruited to complete three 5-min treadmill walking trials at 2.5 mph/0% grade, 3.4 mph/0% grade, and 3.2 mph/5% grade. Body composition is being assessed with air displacement plethysmography (BodPod, Cosmed USA). Steady-state $\dot{V}O_2$ and respiratory exchange ratio (RER) are being assessed at rest and during each walking trial (K5, Cosmed USA) and subsequently being used to calculate gross and net values for MCOW ($J \cdot kg^{-1} \cdot m^{-1}$). Results will be analyzed using multiple linear regression analysis with the MCOW as the dependent variable and primary predictors including percent body fat, fat mass, and fat-free mass. It is hypothesized that body composition, including body fat percentage and fat-free mass, will be significantly associated with the MCOW.

Abstract Name: Natural or Artificial? Variation in Nest Material Types and Acquisition Decisions in House Sparrows (*Passer domesticus*)

Animal behavior provides insight into the decision-making strategies animals use to balance costs, benefits, and competition to maximize their fitness. In birds, nest material collection requires a unique set of behavioral choices, as individuals evaluate and acquire resources for reproductive investments rather than caloric consumption. Urban environments increasingly present novel ecological conditions for birds, including the introduction of anthropogenic material into nesting habitats, however the behavioral and reproductive impacts of incorporating these materials into nests remain poorly understood. Through this study, I investigate how house sparrows (*Passer domesticus*), a widespread urban species, preferentially select feathers or plastic nest materials, make behavioral choices, and socially interact during nest material collection, as well as the reproductive outcomes associated with material composition of nests. To address this, we deployed experimental “choice stations” across a field site that offered equal quantities of color-coded feathers and plastic twice weekly from May through August of 2025. Nest boxes and stations were mapped, allowing us to quantify the distance traveled during nest-material collection. Continuous video recordings documented individual behaviors, including approaches, material acquisition attempts, handling time, load size, aggressive interactions, and patterns of visitation following initial resource patch discovery. Individual plumage morphology also enabled us to compare behavior between males and birds expressing female or juvenile plumage while gathering materials. We monitored the house sparrow nests throughout the breeding season and recorded the associated reproductive outcomes of each nest. After fledging, we collected and dissected nests to quantify proportions of different natural and anthropogenic materials, including those sourced from experimental trials. By combining material collection behaviors with reproductive monitoring, this study offers insight into material choice, acquisition strategies, competition, profitability, and reproductive outcomes in urban birds, contributing to the understanding of animal behavior in anthropogenic landscapes.

Abstract Name: Fragments of Faith: A Preliminary Study on Catholic Saint Relics

This research explores how the Catholic Church identifies which bodily remains are used in first-class relics of canonized saints. In Catholic tradition, a first-class relic refers to a part of the saint’s body, such as a bone, a lock of hair, or even a tooth. Although relic veneration has been part of Catholic practice for centuries, the details surrounding how these sacred remains are selected and formally recognized are often unclear. To investigate this process, Father Brian Capuano and Dr. Maria Christina Mairena, an archivist with the Catholic Diocese of Richmond, were interviewed. Their insights help clarify how sainthood is officially recognized, how relics have been authenticated across different historical periods, and why saints continue to hold a meaningful place in the faith. Examples discussed included the incorrupt body of Saint Catherine of Bologna and the preserved tooth of Saint Apollonia. These bodily remains are recognized relics based on certain factors such as the condition of the body, the symbolic significance, and the devotional needs of local communities. These findings suggest that the designation of a first-class relic is guided by a combination of theological reasoning, historical tradition, cultural relevance, and at times, practical considerations. Relics of Catholic saints are more than physical remnants. They reflect how the sacred becomes tangible and how the bodily remains of saints serve as powerful focal points for faith and devotion.

Abstract Name: The Effects of Clicker Training and Food Rewards as Behavior Modification with Positive Reinforcement in a Horse

ABSTRACT: This study investigates the impact of clicker training combined with a food reward to modify adverse behaviors in a horse. Clicker training, a form of positive reinforcement, uses a distinct auditory cue followed immediately by a food reward to signal a desired behavior. The study is based on one horse that has been used extensively in research studies that has recently developed an aversion to needles and being handled by students. Judy, a 12 year old Quarter Horse mare, began to associate student interaction in a negative way. She became difficult to catch in the pasture and showed signs of agitation and stress by pinning her ears back, trying to bite students, and vigorously shaking her head to avoid being touched near her jugular vein. Through methodical desensitization steps, clicker training, and food rewards, Judy's behavior has been positively transformed in a matter of weeks. This study shows the importance of using clicker training methods and positive reinforcement and how quickly these methods can impact the overall behavior of a horse.

Abstract Name: Consumed by Grief: Monstrous Embodiment and Materializing Queer Affect in Gerardo Sámano Córdova's *Monstrilio*

Decades of queer theory have explored the subjectivities that have been deemed to exist between and outside of binaries defining normative sexual behavior and gender-based identities. An identity that obfuscates these socially constructed bounds destabilizes a subject's social intelligibility, placing them in what Hil Malatino calls the "realm of the monstrous". Despite social progress and the mainstreaming of queer difference, many queer subjects still live within this realm. Existing in a monstrous subject position elicits distinct affects—often rage—which Susan Stryker famously connects to the literary monster in "My Words to Victor Frankenstein." Using Mary Shelley's *Frankenstein* as an allegory, Stryker identifies transgender rage as a transformative affect, which trans subjects can embody to exact agency amidst institutional exclusion. However, in recent fiction, the resounding affect of some queer monsters is not the productive rage that ruptures engendered understandings of human ontology, but grief. Gerardo Sámano Córdova's *Monstrilio* presents a grief-stricken monster, borne by a mother's will to reanimate her lost child. The novel puts forth a queer family's efforts to reinhabit a queer ideal, where monstrous embodiment serves as a repeated confrontation of the impossibility of doing so; the monstrous materializes a queer history that the family can never be rid of, one that elicits a consuming grief in the present. In exploring the affective experience of this family's life with the monstrous, this paper will explore the productive potential of representing queer grief in a post-Stonewall society. Calling on Heather Love's *Backward Feelings*, it will argue the confrontation of grief as necessary to accessing a queer potentiality, specifically examining the literary monster's bodily materiality as a conduit for doing so. Bridging queer affect theory and literary criticism, this paper explores

the imaginative potential of the monstrous amidst a moment in queer history where rage is transmuted into grief.

Abstract Name: Characterizing the early interferon response against MCMV and determining the role of ZBP in that response

Z-nucleic acid Binding Protein 1 (ZBP1) is a host sensor that detects viral nucleic acids and initiates antiviral responses, including programmed cell death and cytokine production. One key cytokine, interferon beta (IFN β), plays a critical role in halting viral replication. Murine cytomegalovirus (MCMV), a herpesvirus model used in mice, has evolved mechanisms to both activate and suppress IFN β signaling. While ZBP1 is known to mediate antiviral cell death, its role in initiating the Type 1 interferon response remains unclear. This project aims to investigate how ZBP1 contributes to early IFN β activation during MCMV infection and how this affects viral replication

Abstract Name: Alcohol's Impact on Spontaneous Conversation Topics Among Strangers

Alcohol is deeply embedded in social life, frequently serving as a social lubricant that facilitates bonding and group cohesion. Despite its well-documented risks, including the potential development of alcohol use disorder, many individuals continue to drink, suggesting that the social rewards of intoxication are powerful motivators. Although prior research has established that alcohol enhances social bonding and positive affect, little is known about how intoxication influences the content of social interactions. Specifically, few studies have examined how alcohol alters language use, the primary medium through which humans connect and form relationships. The present study aims to investigate how alcohol affects the subject matter of spontaneous social conversations. Drawing on data from Dr. Kasey Creswell's NIH-funded Behavioral Alcohol Responses study, we will analyze transcribed conversations among 393 heavy-drinking young adults (ages 21–29) who engaged in 36-minute unscripted group discussions after consuming either alcohol (target BAC = 0.08) or a placebo. Prior analyses revealed that alcohol increased positive socioemotional experiences and group-level coordination; however, these analyses focused solely on speech duration rather than content. In this project, human-generated transcriptions of recorded sessions will be analyzed using large language models and natural language processing techniques to identify recurring themes and conversational risk-taking. Multi-level modeling will assess whether beverage condition predicts differences in conversational content while accounting for the nested data structure (participants within groups). We hypothesize that alcohol will promote discussion of more personal and socially risky topics, reflecting its disinhibiting effects. By examining how intoxication shapes language, this research seeks to uncover mechanisms underlying alcohol's socially reinforcing properties and contribute to a deeper understanding of why individuals persist in alcohol use despite its known harms.

Abstract Name: Handel and the Economic Instability of Italian Opera in Eighteenth-Century London

Italian opera dominated London's theaters in the eighteenth century, though its popularity masked an unstable economic and social foundation. My research enters the broader speculation that opera has never truly been profitable. I focus on George Frideric Handel (1685-1759) and the writing and production of Italian opera in London. At the King's Theatre and the Royal Academy of Music, Italian opera rose to prominence under George I, continuing into the middle of the century. While Handel is often treated as a godfather-esque composer, celebrated for the Messiah, I look instead at his productions and failure to sustain an Italian operatic presence in London despite his fame and royal backing. Through historical musicological methods and archival research at the British Library in May 2025, this project analyzes primary documents related to Handel's productions and builds on the work of scholars such as Donald Burrows and Judith Milhous. This study asks what about London's society and culture made stability infeasible. Several factors emerge. First, London's musical culture resisted opera; since Henry Purcell (1659-1695), few composers had established a sustainable operatic tradition alongside the long-dominant stage play and masque, which emphasize spoken text. Second, the audience demanded performers who were not the best in England but the best in Europe, which produced ballooning budgets and infamous feuds, including famous diva conflicts like those around Francesca Cuzzoni, whose contracts reached the equivalent of millions today. Third, Italian opera was not profitable even in major Italian cities; it had two advantages London lacked: performance in the local vernacular and greater government support. These findings lead to broader questions about operatic sustainability: Would Handel have succeeded with stronger government backing? And what might've happened if his theatre hadn't been dependent on elite patrons? Could a middle-class model have offered a viable path forward?

Abstract Name: The Luso-African Ivory Trade: Missing Depictions of Western Black Africans and Luso-African Ivory Carvings in 16th-17th century Renaissance Paintings

This analysis of peer-review research on the Luso-African ivory trade and paintings from 16th-17th century Europe of Luso-African ivory spoons and the Envoy of Congo argues for the potentially missing identification of depictions of black Africans and Luso-African ivory carvings in 16th-17th century Portuguese paintings. This paper argues that depictions of black Africans with Luso-African ivory carvings exist, or once existed, through the analysis of the trade relationship between Portugal and Sierra Leone, the Congo, and Benin, European accounts of the Luso-African ivory trade, the relationship between Christianity and black Africans in both Europe and Western Africa, the lack of stereotypes in the representations of the Envoy of Congo and the ivory spoons, and the pattern of representations of the Luso-African ivory spoons and the Envoy of Congo. During the Luso-African ivory trade of the 16th-17th century, Portugal commissioned ivory spoons, salt-cellars, and figures to be carved in Sierra Leone, Benin, and the Congo.

Portuguese paintings from the 16th-17th century represent Luso-African ivory spoons and a Congolese woven mat in Christian compositions in a frequent and consistent manner. The Envoy of Congo with the ivory tusk may indicate that the representation of a Western Black African subject with ivory was not unusual. This review analyzes primary and secondary accounts from Europeans along with peer-reviewed articles on the cultural and trade relationship between Portugal and black Africans in Western Africa and Europe from the academic journals African Arts, History of Africa, Renaissance and Reformation, Renaissance Studies, and Transafrican Journal of History. This paper argues that the paintings representing Luso-African ivory spoons and the Envoy of Congo with an ivory tusk may indicate a larger pattern of Western Black Africans represented alongside ivory in paintings from 16th-17th century Portugal that are yet to be identified or no longer exist.

Abstract Name: Extracting Biopsychosocial Insights from Motivational Interview Transcripts on Chronic Pain Using Natural Language Processing

Effective communication is essential for high-quality chronic pain care, yet over 80% of individuals with chronic pain report difficulty expressing their experiences in ways that feel understood by others [1]. These communication challenges are intensified by the multidimensional nature of chronic pain, which often includes rare or complex conditions and highly individualized biopsychosocial factors. Traditional assessments capture only fragments of this complexity, leaving clinicians without a holistic understanding of a patient's lived experience. Natural Language Processing (NLP) offers a scalable method for analyzing rich, narrative data, but its application to patient-centered chronic pain communication remains limited. The objective of this ongoing study is to develop and evaluate an NLP-driven annotation and analysis pipeline capable of extracting biopsychosocial insights from patient narratives to support more comprehensive pain assessment. We collected over 30 chronic pain narratives using a Motivational Interviewing protocol, and then automatically transcribed and manually corrected for accuracy. Each transcript was annotated using two complementary frameworks: (1) the International Classification of Functioning, Disability, and Health (ICF) to categorize functional and contextual factors, and (2) Aspect-Based Sentiment Analysis to capture positive, negative, and neutral emotion valence. Annotated data were then analyzed to identify recurring themes, characterize patterns of healthcare system interaction, and highlight social and environmental influences that shape patients' pain experiences. The purpose of this abstract is to share this NLP annotation and analysis pipeline, including data collection procedures, coding frameworks, and early analytic strategies, so that clinicians and researchers may adopt, refine, or extend these methods in their own work. By disseminating this process, we aim to support broader integration of patient narratives into clinical decision-making and contribute to more personalized, empathetic, and effective chronic pain care.

Abstract Name: Protein Kinase A Activity Decreases at Microtubules in Response to Brain-Derived Neurotrophic Factor

The shape of the dendritic arbor determines how neurons receive information. cAMP-dependent protein kinase (PKA) is a signaling molecule that plays an important role in the regulation of dendrite branching. PKA activity can be modulated by brain-derived neurotrophic factor (BDNF), a growth factor that regulates neuronal plasticity and increases arborization in hippocampal neurons. PKA activity is generally assessed in neuronal lysate, which does not determine how PKA activity is regulated at specific sites in cells, such as microtubules. To determine how BDNF affects PKA activity at microtubules, we transfected hippocampal cultures with the tAKAR4 α construct, a PKA activity sensor that localizes to microtubules. tAKAR4 α contains two fluorophores, the donor mCerulean and acceptor mVenus, separated by a region that is phosphorylated by active PKA. This phosphorylation brings the fluorophores closer, decreasing the lifetime of mCerulean. We measured PKA activity of transfected neurons using Fluorescence Lifetime Imaging Microscopy (FLIM), which quantifies changes to donor lifetime. We imaged neurons expressing tAKAR4 α or nonphosphorylatable mutant tAKAR4 α T402A (negative control with a stable lifetime) treated with vehicle or BDNF using a Leica SP8-STED microscope. In primary, secondary, and tertiary orders of dendrites, mCerulean lifetime in tAKAR4 α increased after ten minutes in neurons treated with BDNF compared to those treated with vehicle, corresponding to a decrease in PKA activity at microtubules. We assessed PKA activity in neuronal lysate treated with vehicle or BDNF and found that BDNF increased total PKA activity. Taken together, our results suggest that the regulation of PKA activity by BDNF spatially differs in neurons. Future studies will assess how BDNF affects PKA activity at other sites, and how these changes affect the shape of the dendritic arbor. Understanding the mechanisms underlying dendritogenesis will aid in the development of therapeutics for neurodegenerative disorders associated with a loss of dendrites on hippocampal neurons

Abstract Name: Exploring Zinc-Nickel Thin Film Morphology and Thickness on Manufactured Surfaces

Thin films are important in many technologies, from electronics to protective coatings. The way these films grow can change depending on the shape of the surface they are deposited on. In this project, we studied how a ZnNi thin film deposited onto three different surfaces: a flat plate, bolts, and a screw. Using scanning electron microscopy (SEM), we examined the overhead surface morphology and measured film thickness through cross-sectional imaging. Energy dispersive X-ray spectroscopy (EDS) was also used to determine the chemical composition of the film. Comparing a cross-section of the flat plate to the deposition on more complex surfaces, we observed differences in how the thin film covered the surfaces and how its thickness varied. This study shows how surface geometry influences thin film growth and provides insights for improving thin film deposition on non-flat materials.

Abstract Name: Self-awareness and Agency in Psychiatric Conditions: a Phenomenological Perspective

This paper presents a phenomenological perspective on the relationship between self-awareness and agency in the context of mental health conditions. Self-awareness involves reflective processes through which individuals evaluate their thoughts, emotions, identities, morals, and personalities. Agency, as defined by Bayne (2011), refers to the outward expression of one's capacity to act and make decisions. Self-awareness gives rise to internalizations, which in turn shape a person's sense of self and contribute to their agentive experiences. In psychiatric conditions, however, this relationship between self-awareness and agency often becomes disrupted. This paper examines such disruptions, focusing particularly on schizophrenia and anarchic hand syndrome, where the first-person perspective, the core of self-awareness, is fundamentally altered. I argue that existing models, specifically the Missing Phenomenological Model and the Perturbed Phenomenological Model (Bayne, 2011), inadequately capture the full spectrum of phenomenological disturbances in agency seen in mental illness. In response, I propose an alternative framework: the Split Self-Model of Agentive Experience. This model accounts for a broader range of symptoms and provides a more comprehensive understanding of how agency and self-awareness interact in psychiatric disorders.

Abstract Name: Cyclone Kitchen: A Pilot Evaluation of Hands-On Nutrition Education in Iowa

Many Iowans struggle with everyday nutrition practices. Statewide data indicate that many Iowans reported "poor to moderate" diet quality and their health as "poor or fair". Teaching kitchens offer a straightforward, practical approach by providing individuals with a space to cook, learn, and establish healthier routines under guidance. Cyclone Kitchen is a statewide initiative that combines hands-on cooking with practical nutrition guidance, encouraging Iowans to gain confidence in the kitchen and establish healthy eating habits that support long-term health. This initiative seeks to address a clear gap in accessible food and nutrition education across Iowa, particularly in rural areas where teaching kitchens are limited. Each teaching kitchen event combines cooking tasks with brief explanations and time for reflection, helping people connect what they have learned to their own routines. Two pilot events were offered to extension staff and friends of Extension to assess its structure, delivery feasibility, and consumer-receptiveness. The pilot brought together 14 participants and was led by nutrition faculty and Extension Educators. To assess its effectiveness, Cyclone Kitchen participants completed a 5-question evaluation that was available online and in paper format. The evaluation examined the clarity of the course structure, the impact of the learning objectives and materials, and the level of engagement with activities, assessments, technology, and instructor interactions. Participants also shared what support their kitchen experience provided, any challenges they faced, and how their individual habits shaped their overall experience. Evaluation data provided on the paper form are being entered into Qualtrics. These data will be analyzed using descriptive analysis to determine the effectiveness of the pilot programs.

Abstract Name: Fractured Foundations: Does Divorce Impact College Students' Academic Performance, Mental Health, Financials, and Interpersonal Relationships?

The concept of parental divorce is one of the most frequently experienced developmental stressors, and current literature provides limited and often contradictory information regarding how these divorce experiences may affect emerging adults in higher educational institutions. This mixed-methods study examines how the impact of parental divorce relates to the mental health of undergraduate college students, their economic stability, their academic success, as well as the interpersonal relationships that they develop while in college. A sample of 200 undergraduate students (ages 18–25) from Auburn University will complete a comprehensive online survey assessing depressive symptoms (PHQ-8), financial instability (PFW; IFDFW), family functioning, attachment, communication quality, loneliness, academic self-efficacy, engagement, and self-reported GPA. Additionally, the study examines whether financial instability mediates the relationship between parental divorce and the psychosocial or academic outcomes of college students. Following the survey, a subset of up to 20 students with divorced parents will participate in semi-structured interviews to assess their lived experiences, perceived impacts of divorce, and relational or financial challenges during college. Survey data will be analyzed using correlational and multivariate modeling to evaluate direct and mediating effects, while qualitative interviews will be coded thematically to identify patterns in students' narratives. Findings from this ongoing project aim to (1) test whether parental divorce influences depressive symptoms, financial instability, quality of interpersonal relationships, and academic performance of emerging adult college students, (2) test whether financial instability mediates or explains the effects of divorce, and (3) examine the perceptions and experiences of college students with divorced parents.

Abstract Name: Exploring the Psychological Roots of the Authenticity-Aesthetic Paradox

This research examines the rationale behind the Authenticity-Aesthetic Paradox- the reasoning behind why women tend to prefer digitally altered images even though it may conflict with their values of authenticity. Despite Gen Z's stated preference for authentic content, this generation still engages with highly curated, inauthentic content, often preferring digitally manipulated versions of an image instead of the original. Building upon extant literature, this research examines how media literacy, body esteem, and self-congruence may influence consumer preference, liking, and trust of an ad campaign while examining how these effects can vary by whether an image was digitally manipulated or not. The expected conclusion is that these constructs significantly impact whether individuals fall victim to the authenticity-aesthetic paradox. The paper begins with an introduction that outlines the evolution of beauty marketing from traditional print magazines to today's digital landscape, where unrealistic online beauty advertisements have created heightened beauty ideals. This is followed by a literature review that establishes the psychological framework for the conceptual model. While existing quantitative research documents the paradox, a critical gap remains in understanding the qualitative reasons that underlie these deep-rooted issues and the preference for inauthentic content. To determine what causes individuals to experience the authentic-aesthetic paradox, an online survey comparing an edited and unedited image will be distributed to a national sample, and several focus groups will be conducted with Gen Z students across U.S. universities. The objective is to provide a better understanding of why individuals prefer heavily edited content. By understanding what causes individuals to experience the paradox and how the psychological constructs influence image preference, individuals can better protect themselves from the mental health risks that stem from repeated exposure to unrealistic beauty standards, while marketers can make more responsible decisions about how and when to use digitally altered imagery.

Abstract Name: Methods, Materials, and Machines: A Craft-Based Investigation of Creative Technologies

This research explores the intersection of craft practices and creative technologies in fine art making, challenging the perceived divide between traditional and digital methods. As a Craft/Material Studies student and a student worker at The Workshop, I engage with both historical, hands-on processes and emerging digital tools. While new technologies are often positioned as replacements for traditional craft, and craftspeople may resist digital methods, this project reframes creative technology as a tool that can be integrated rather than opposed. Through hands-on experimentation, I will investigate how merging these approaches expands artistic possibilities, with an emphasis on process rather than novelty. This research will result in a body of work demonstrating the potential of interdisciplinary making, offering insight into how digital tools can complement, rather than replace, traditional craft. This project also challenges the false dichotomy between traditional craft practices and emerging creative technologies by demonstrating how their integration can foster innovation in fine art. The tension between traditional techniques and technological

advancement has long shaped craft practices, from the industrialization of handmade goods to the rise of digital fabrication. Today, as emerging technologies redefine creative production, similar debates persist about authorship, labor, and the role of the maker. By merging traditional and digital methods, this project highlights new possibilities for material exploration, conceptual development, and interdisciplinary practice. It also engages in broader conversations about how craft and technology continue to shape artistic identity in the digital age. By showcasing these intersections, this research aims to inspire artists, craftspeople, and technologists to embrace cross-disciplinary approaches, fostering a more inclusive and forward-thinking art landscape. This further bridges the gap, not only between craft and technology, but also between the artists who occupy those respective fields.

Abstract Name: An Insight on the life of Milton Glaser: Works and achievements

This paper explores the life, career, and cultural impact of Milton Glaser, one of the most influential designers that came out of the 20th century. Tracking his journey from a talented child in the Bronx to a major figure in modern visual communication, the paper highlights the important experiences that shaped Glaser's artistic voice, including his early training, education at Cooper Union, and the founding of Push Pin Studios. It examines several of Glaser's most iconic works, including the psychedelic Bob Dylan poster and the globally recognized I <3 NY logo. These works illustrated how he fused fine art techniques with contemporary graphic design to change the game in the design field. Through the journey of his career, the paper discusses Glaser's role in establishing New York Magazine. He then ventures into environmental and commercial design, and his long career as a teacher and author. Through interviews, archival research, books, and movies, this paper shows that Glaser not only transformed the visual landscape of his time but also demonstrated the power of design to influence culture, shape public perception, and create lasting symbols of identity.

Abstract Name: The Importance of Hippotherapy: Improving the Lives of the Disabled Through Alternative Therapy

For centuries, horses have been suggested as "healers" and "helpers," although it wasn't until the 1900s that horseback riding was scientifically proven as a treatment and rehabilitation method. The exploitation of hippotherapy, the implementation of the three-dimensional pelvic movement stimulated by the oscillation and gait of the horse to combat symptoms of diseases and disorders, has since become a flourishing field of study, but one that is often overlooked. Benefits of hippotherapy often include increased motor neuron function, facilitating proper anatomical alignment, and reducing spasticity. This research analyzes the diverse and dynamic nature of treatment that hippotherapy facilitates, exploring the utilization of hippotherapy and its effectiveness of rehabilitation for those facing chronic non-progressive encephalopathy (also known as Cerebral Palsy). Cerebral Palsy, a non-degenerative disorder, is a result of a neural lesion or cranial damage and it often results in issues such as reduced mobility, decreased range of motion, and increased spasticity. As

a result, this research focuses on the effectiveness of hippotherapy's unique ability to offer a multidisciplinary rehabilitation framework including the reduction of spasticity and fatigue as well as increase in range of motion and increased neuromuscular activation, muscle strength, balance, and overall coordination. Additionally, this study includes how hippotherapy, an underutilized alternative form of therapy, has been and continues to be proven as an effective treatment and rehabilitation. In the United States alone, 1 in 345 children suffer from a form of Cerebral Palsy; however, only 2% of those who could benefit from hippotherapy actually receive it. Reviewing this research demonstrates the immense benefits that hippotherapy provides and breaks down how it combats symptoms associated with Cerebral Palsy, proving it is more than "just horseback riding."

Abstract Name: External Standard versus Standard Addition Quantification of Nicotine in E-Liquids Using High Performance Liquid Chromatography (HPLC)

Many studies show significant inconsistencies in the amount of nicotine reported on e-liquid product labels and the amount of nicotine detected in the e-liquids. This is of concern because e-cigarette users that rely on the labeling of the e-liquids to regulate their nicotine intake for smoking cessation could be negatively impacted if the nicotine levels are incorrect. Published methods for quantification of nicotine in e-liquids rely on external standards for the quantification of nicotine in e-liquids, but this method does not account for the varying components in the matrix of e-liquids. The aim of this project is to compare the results from the quantification of nicotine in e-liquids obtained using the external standard method to those obtained using the standard addition method to determine previously observed inconsistencies could be due to a matrix effect.

Abstract Name: Portable MRI unit with Independent Magnetic Field Variance

The current implementation of Electromagnets in the modern MRI and its robust construction is the leading cause of high costs in order for its manufacturing. This in turn causes MRI's and their use to be a high cost expense for many, for the patient to utilize and for the medical establishment to maintain. An additional expenditure is the extensive coolant used for the resulting heat caused by the Electromagnetic Gradient when they are in use, the cause being from the high amounts of Current. A possible remedy for this problem is the implementation of Gradient free Permanent Magnets, but this in turn causes a loss of quality in image resolution and a set magnetic field. In order to create a way to control the field strength, Spatial Encoding in which individual magnets move their physical position was proposed so that the operator has precise control. The main obstacles in order to achieve this, currently, are a method of which to house the magnets so that the fields they exert and the ones that are exerted on them do not unnecessarily move the magnets and foul the field precision. An additional design consideration is to create the whole apparatus out of readily available

PLA filament and 3-D print it to design specifications. This in turn poses an obstacle, that in order to create a quality piece of equipment with high tolerance is entirely dependent on the quality of the 3-D printer itself. If cost is to be a major consideration, then this is one that must be addressed by physical design and iteration with more affordable models that are readily available. This in turn must be solved with design iterations and equipment placement on the physical device that will not impair the modularity of the desired machine and its intended use.

Abstract Name: Using Unmanned Aerial Vehicles to Autonomously Detect Fusarium Head Blight in Triticum Aestivum at a Field Scale

Fusarium Head Blight is a major fungal disease that affects Triticum Aestivum (winter wheat). It produces harmful mycotoxins that threaten both crop yield and safety. Early and accurate detection is necessary for reducing agricultural and economic losses. This research explores how Unmanned Aerial Vehicles equipped with advanced imaging sensors can autonomously detect Fusarium Head Blight at a field scale. This, in turn, will offer a faster and more cost-effective alternative to traditional laboratory testing methods. The growing use of Artificial Intelligence and Machine Learning in agriculture, primarily through Computer Vision, enables high-precision analysis of aerial imagery. By combining traditional cameras, thermal, and hyperspectral sensors, Unmanned Aerial Vehicles can capture multi-dimensional data on crop health. The research question guiding this study is: Can we use Unmanned Aerial Vehicles to Autonomously Detect Mycotoxins in Triticum Aestivum (Winter Wheat) at a Field Scale? Combining data from multiple sensors will allow deep learning models to identify Fusarium Head Blight infection more accurately than single-sensor approaches. To test this, Unmanned Aerial Vehicles will collect imagery from experimental wheat plots that have been grown specifically to research Fusarium Head Blight and treatments. The images will be processed to classify and localize areas showing the infection. The layered dataset will then be analyzed and compared to previous photos that were used to train the Machine Learning model. Anticipated results include a significant improvement in detection accuracy and the ability to map the distribution of the infection across large fields. This study aims to demonstrate how integrating Artificial Intelligence, Machine Learning, and Unmanned Aerial Vehicle technologies can transform Fusarium Head Blight detection into an automated and scalable process, advancing precision agriculture and contributing to global food security.

Abstract Name: EPIGENETIC EFFECTS ON OFFSPRING OF ADULT RATS EXPOSED TO CHRONIC VARIABLE STRESS ON ENHANCED NICOTINE-SEEKING BEHAVIOR

Nicotine remains very relevant, and exposure to tobacco products can alter behavior and neurobiology from

generation to generation (Goldberg et al., 2021). Exposure to chronic stress has been seen to impact human development and the development of disease, resulting in an increased risk of substance-seeking behavior (Jenkins et al., 2021). The effects of parental exposure to stimuli on subsequent developmental changes have previously been studied using models of fear conditioning in rats whose parents were exposed to odorous stimuli. Such studies utilized conditioned fear responses to acetophenone in paternal rats prior to conception to analyze transgenerational and multigenerational effects on the following generations. Altered epigenetic marks, specifically DNA hypomethylation in sperm of F0 and F1 generations, were found to attribute to transgenerational inheritance of behavioral and neurotoxic changes in offspring without prior exposure to the odor (Dias & Ressler, 2014). Few studies, however, have investigated the epigenetic effects on enhanced nicotine seeking behavior of offspring of adult rats exposed to chronic variable stress. Therefore, this study will investigate the effects of prenatal maternal chronic variable stress on conditioned place preference to nicotine in subsequent generations and the epigenetic processes involved. One group of female rats will be exposed to 20 days of randomized stressors, while control rats will not receive any exposure treatment. Following exposure treatment, animals will be bred, and offspring will undergo place preference conditioning to nicotine (0.175 mg/kg, base, s.c.). To date, preliminary data indicate that animals bred from a mother exposed to chronic variable stress exhibit higher place preference for nicotine compared to animals bred from controls. In addition to providing evidence of how the experiences of a parent before conceiving offspring can influence the function of the nervous system and behavior of offspring, the results obtained can have important implications for the treatment of addiction.

Abstract Name: Building a Nuclear Future on a Radioactive Ground: The Evolution of the Kazakhstani Government's Nuclear Narratives

What does a state have to gain by downplaying its victim narratives? Reconciling traumatic histories with contemporary modernization goals is a challenge faced by many states, provoking questions about state building and memory politics. In October 2024, Kazakhstan held a country-wide referendum on the construction of its first nuclear power plant. 71% voted in favor. This outcome is surprising given Kazakhstan's background of traumatic Soviet nuclear testing and the country's complex relationship with nuclear weapons. It is perplexing that the government's narratives leading up to the referendum largely ignore this nuclear legacy. This is a clear departure from Kazakhstan's victimhood memory politics surrounding the Holodomor, the gulag system, and other Soviet-era suffering. This project seeks to analyze how the Kazakhstani government's narratives in the nuclear sphere have evolved since independence, in order to understand how such public support became possible. Kazakhstan had two paths it could have taken: continue to be a nuclear victim or become a nuclear victor. I argue that Kazakhstan has deliberately shifted its narrative to downplay victimhood and emphasize modernization. This shift is not solely for strategic political gains, but also linked to memory, reflecting deeper state-building strategies utilized to develop both domestic identity and international reputation. Presidential addresses, official statements, and media coverage surrounding key moments in Kazakhstan's nuclear history post-independence are uploaded into qualitative data analysis software (NVivo) and coded for themes such as victimhood, modernization, inward-versus outward-oriented messaging, and identity versus reputation building. Word frequency and matrix coding queries as well as longitudinal coding comparison help track the evolution of these narratives. By understanding how these themes develop and change over time, the project hopes to show that the 2024 referendum results were not a shock, but rather a culmination of a long process of state narratives.

Abstract Name: Investigating the Effects of Inflammatory Stress on Hematopoietic Stem Cells in Culture

Acute myeloid leukemia (AML) occurs when healthy hematopoietic stem and progenitor cells (HSPCs) are transformed into leukemic stem cells (LSCs) through genetic mutations. The development of immortalized bone marrow endothelial cells (BMECs) allows us to culture and expand HSPCs. Inflammatory insults to the marrow microenvironment are known to impair self-renewal and drive myeloid-biased differentiation of HSPCs resulting in transformation of healthy stem cells to leukemic ones. Because of their importance in pathogenesis, here we examine the effects of lipopolysaccharide (LPS) on HSPCs. LPS, an endotoxin found in Gram-negative bacteria, causes immune cells to secrete inflammatory cytokines such as IL-6. These cytokines can induce susceptible stem cells to proliferate and outcompete other blood cells. Despite the crucial role of the marrow microenvironment on HSPCs, the influence of an inflammatory environment on HSPC fate is not well understood. The co-culture system we use consists of murine bone marrow cells enriched for stem cell factor receptor (called cKit), grown on a layer of BMECs. Experimental groups are supplemented with LPS to model inflammation or infection. We hypothesize that several phenotypic changes will emerge in the HSPC compartment upon analysis with flow cytometry. Among these changes we predict that the HSPCs will differentiate in a myeloid-biased fashion and total cells in the HSC compartment will decrease. My future work includes using single-cell transcriptomics to detect changes in quiescent or inflammatory genes of HSPCs and testing their long term engraftment capacity upon transplantation. Our goal is to understand how inflammation influences HSPCs and subsequent leukemogenesis.

Abstract Name: Investigating the Moderating Effect of Athlete Status on the Relationship Between Extraversion and Perceived Social Support

[Data Collection in progress]The present study investigates whether the established relationship between extraversion and perceived social support differs between undergraduate athletes and non-athletes. Participants at a medium-sized Liberal Arts university are completing an online survey via QualtricsXM, which contains an informed consent form, a brief demographics questionnaire (where participants will indicate whether they are a college athlete or not), the Big Five Inventory (BFI; John & Srivastava, 1999), the Multidimensional Scale of Perceived Social Support (MSPSS; Zimet et al., 1988), the Sense of Belonging Scale (SBS; Mellinger et al., 2023), the Need to Belong Scale (NTBS; Leary, 2013), the UCLA Loneliness Scale (Russell et al., 1978) and a debriefing. Researchers hypothesize that: (1) the predictive nature of extraversion on perceived social support will be significantly stronger in athletes than in non-athletes; (2) athletes will display more extraversion than non-athletes; and (3) athletes will report more perceived social support than non-athletes. Hypotheses 2 and 3 will be tested using Pearson correlation and independent-samples t-tests. Hypothesis 1 will be tested using a moderated multiple regression, with extraversion as the predictor, perceived social support as the outcome, and athlete status as a moderator. An interaction term (Extraversion $\times$ Athlete Status) will be included to assess whether the strength of the relationship differs across groups. Findings from this study may offer insight into how personality traits interact with contextual factors (e.g., athletic participation) to influence perceived social support. The Sense of Belonging, Need to Belong, and UCLA Loneliness Scales are included to provide additional reasoning

behind our findings. Ultimately, this study has implications for targeted interventions to promote well-being in college populations, and it could be easily replicated at other universities.

Abstract Name: Engineering Nanofluids for electrochemical applications: Thermophysical properties of surface modified silica nanoparticle suspensions

Colloidal suspensions of nano-sized particles (NP) in aqueous media have been historically investigated for their superior thermal properties. Multi-functional suspensions of nanosized particles (nanofluids) have also been investigated as catalytic media for chemical reactions, solar harvesting, and battery applications. Complex and novel behaviors exhibited by such fluids have resulted in theories proposed to explain their thermophysical properties such as viscosity and thermal conductivity, but their use in electrochemical systems remains relatively novel. Here, we report on the use of silica-based NPs and their surface modification using functionalized silanes to prepare stable nanofluids in aqueous base fluids. Nanofluid preparation of both pristine and surface-modified NPs uses a horn-sonication setup under careful temperature control. Particle size, morphology, grain size, colloidal stability and crystallinity of the nanoparticle were confirmed through various analytical methods such as electron microscopy (SEM), sedimentation tests, dynamic light scattering (DLS), X-ray diffraction (XRD), thermogravimetric analysis (TGA), and Fourier transformed infrared spectroscopy (FTIR). Furthermore, we report on various grafts explored for the surface modification step, which aims to decrease the intermolecular attraction between individual NPs by introducing the silane graft. The graft's presence is expected to minimize the formation of aggregates after sonication and for the suspension to not settle under gravity over time. We investigate its effects on nanofluid stability to reveal optimal modification conditions for electrochemical applications. Finally, we have also analyzed these nanofluids using finite element (FE) modeling in COMSOL Multiphysics, incorporating diffusion, charge-transfer kinetics, and particle-tracking physics. This approach helps analyze nanoparticle motion, stability, and interactions in a flow-type electrochemical reactor being developed for electrocatalytic conversions.

Abstract Name: Ratios of Essential Fatty Acid Intake Associated with Blood Pressure and Triglyceride Levels in Female College Students: A Cross-sectional Study

Background: Blood pressure (BP) and fasting triglyceride (TG) levels are parameters of metabolic syndrome, a cluster of risk factors associated with chronic disease. Essential fatty acids (EFAs), linoleic acid (LA), and alpha linolenic acid (ALA) play roles in inflammation and cardiovascular health. Higher LA/ALA ratios are associated with negative health outcomes. This study aimed to identify associations between EFA intake ratio and BP and TG levels in college students. We hypothesized that higher LA/ALA ratios would be associated with higher BP and TG levels. Methods: Participants completed a two-day diet record. EFA intake ratios were

calculated by dividing the percentage of total calories from LA by the percentage of total calories from ALA. Fasting TG levels were analyzed using Cholestech LDX, and BP was measured with an automated sphygmomanometer. Pearson correlations were conducted with SPSS version 29.0. Results: Significant positive associations were found between the ratio of LA/ALA EFA intake and diastolic BP ($r = .138$, $p = .033$) and TG levels ($r = .226$, $p < .001$), in females ($n = 240$). No significant association was observed between the ratio of EFA intake and BP ($n = 113$) or TG ($n = 110$) levels in males. Conclusion: Higher ratios of LA/ALA EFA intake among female college students are associated with elevated BP and TG levels. It is uncertain whether these results are due to the fatty acids themselves or the foods that contain them. Future research investigating specific sources of EFAs could offer a clearer understanding of this relationship.

Abstract Name: Effects of Metabolic Heating Versus Environmental Heating on Temperature-Dependent Sex Determination in the Hawksbill Sea Turtle

The Hawksbill Sea Turtle (*Eretmochelys imbricata*) is a critically endangered species that exhibits temperature sex determination. This form of sex determination can produce a wide variety of sex ratios that can affect the conservation and ecology of this species. Therefore, it is important to monitor sex ratios produced in natural populations. During the current study, nest incubation temperatures were used to predict the hatchling sex ratios from Hawksbill nests laid on the Pearl Cays, Nicaragua. The Pearl Cays are a major nesting area for Hawksbills in the eastern Caribbean. Additionally, this study examined the possible influence of “metabolic heating” (i.e. heat produced by developing embryos) on sex determination. Subsets of nests were examined over a course of 3 years (15 nests in 2010, 19 nests in 2011, and 3 nests in 2013) by the use of paired data loggers. One data logger was placed in the middle of the nest and one data logger was placed in the sand 1 meter from the nest to monitor the beach temperature. Nest versus sand temperatures were examined and compared during the middle third of incubation (the approximate thermosensitive period of sex determination). Additionally, state-of-the-art statistical software (i.e. “EmbryoGrowth” R Package) was used to calculate the thermosensitive period of sex determination and predict hatchling sex ratios. The results suggest that biased hatchling sex ratios are produced on the Pearl Cays, Nicaragua. Additionally, the results indicate that metabolic heating can influence sex determination in this species and should be taken into consideration when estimating sex ratios based on beach temperatures. These findings provide insight on the ecology of the Hawksbill sea turtle and will facilitate the development of better conservation practices for monitoring hatchling sex ratio production in the future.

Abstract Name: Investigating Air Quality Impacts of Rocket Emissions at Cape Canaveral Using Low-Cost

Sensors

Over the past five years, commercial spaceflight activity at Kennedy Space Center in Florida has surged by more than 310%, prompting increased concern over the environmental and public health implications of rocket emissions. Rocket launches emit various air pollutants, notably particulate matter (PM), including black carbon (BC) and nitrogen dioxide (NO₂), both of which are regulated under the U.S. Clean Air Act due to their association with adverse health outcomes. However, existing U.S. Environmental Protection Agency (EPA) monitoring stations are located 20 to 40 miles away from launch pads, making them inadequate for capturing localized, near-field air quality impacts. To bridge this data gap, we deployed low-cost TELLUS AirU Pro sensors, calibrated against reference-grade monitors, at three locations within 15 miles of Launch Pad 39A, including areas adjacent to the pad and near the Apollo Visitor Center. These sensors measured concentrations of PM_{2.5}, PM₁₀, carbon monoxide (CO), ozone (O₃), and nitrogen oxides (NO_x) before, during, and after launch events to analyze pollutant dispersion over time and space. This research provides some of the first ground-based, real-time observations of localized air quality changes associated with modern rocket activity. The results can be used to validate existing models of rocket emission impacts and offer actionable insights for enhancing environmental health and safety strategies. More broadly, the study contributes valuable empirical data to support improvements in atmospheric emissions modeling and promotes the adoption of more sustainable practices across the aerospace sector.

Abstract Name: Investigation of CDH3 in Epithelial Collective Cell Migration using Short Hairpin RNA (shRNA) in MDCK cells

Collective cell migration is driven by the coordinated movement of groups of cells, and is essential for many biological processes. Many factors contribute to the cells ability to collectively migrate, one of which are cadherins, being a source of cell adhesions allowing cells to move together. We hypothesize that knocking down these cadherin-associated genes, using shRNA, inhibits the ability for cells to collectively migrate and form protrusions necessary for migration.. Previous research involving Madin-Darby Canine Kidney (MDCK) cells proves their validity as an exemplary epithelial cell line. In this cell line and others, our lab has observed the expression of a particular cadherin, P-cadherin (CDH3), indicative of a driving force behind the ability of cells to migrate collectively. With these MDCK cells, we compared wild-type (shGFP), and two CDH3 knockdown (shCDH3-1 #4 and shCDH3-2 #2) cell lines, to investigate the role of CDH3 in collective migration. We first conducted 2D wound healing assays to compare the rates of collective migration between the wild-type and CDH3 knockdown cell lines. The rate of migration of the CDH3 knockdown cell lines were significantly less than that of the shGFP cell line, demonstrating CDH3 plays an important role in 2D collective migration. Additionally, we sought to characterize the morphology and extracellular matrix deformation of MDCK shGFP and CDH3 knockdown cells in a 3D space. Cysts were produced for each cell line, by culturing in matrigel. Cysts were loaded into microfluidic devices with collagen. After the first day of imaging, cells were treated with hepatocyte growth factor (HGF) to promote migratory behavior. CDH3 knockdown cysts displayed decreased migratory properties, such as less ability to form protrusions than shGFP cells. CDH3 knockdown cysts also generated decreased extracellular deformation rates, further proving the necessity of CDH3 in collective migration capabilities of epithelial cells.

Abstract Name: Fouling-Resistant Voltammetric Xylazine Sensors for Detection of the Street Drug “Tranq”

As the opioid crisis continues to wreak havoc on a global scale, it is increasingly critical to develop methodologies to detect the most dangerous drugs such as fentanyl and its derivatives, which have orders of magnitude higher potency than morphine. The scientific challenge for chemical detection of fentanyl and its derivatives is complicated by both the constantly increasing synthetic variations of the drug as well as the expanded use of adulterants. One tragically consequential example is the noxious street drug known as “Tranq”, which combines fentanyl or a fentanyl derivative with the veterinary sedative Rompun®, chemically identified as xylazine (XYL). This pervasive street cocktail is exacerbating the already staggering number of fentanyl-related deaths as its acute toxicity poses a danger to medical first-responders and complicates their initial assessment and treatment options for overdose victims. Given the widespread use of XYL as an adulterant, an electrochemical XYL sensor capable of on-site operation by non-experts as a fast-screening tool is a notable goal. This work presents a voltammetry-based sensor featuring carbon electrodes modified with carboxylic-acid functionalized multi-walled carbon nanotubes layered with cyclodextrin and polyurethane membranes for sensitivity and selectivity enhancements. The sensor has critical and robust fouling resistance while providing sensitivity at $950 \mu\text{A}/\text{mM}\cdot\text{cm}^2$, a low limit of detection (~ 5 ppm), and the ability to detect XYL in the presence of fentanyl and/or other non-fentanyl stimulants like cocaine. The demonstrated sensor can be applied to promote public health with its ability to detect and indicate XYL in the presence of opioids, serving to protect drug-users, first responders, medical examiners, and on-site forensic investigators from exposure to these dangerous mixtures.

Abstract Name: Liquid Springs from Wettable Materials

Liquid springs enable storage of energy in the form of interfacial tension upon forcible wetting of lyophobic surfaces. The pressure-volume work performed to compress a liquid into a porous solid can be recovered during spontaneous expulsion, which takes place when pressure is reduced sufficiently below the capillary pressure characteristic of given material of pores and liquid. According to the conventional picture, the requirement for positive intrusion and extrusion pressures limits material choices to substances with solid/liquid contact angles well above 90 degrees. Our work explores an alternative possibility where high wetting pressure is imposed through steric hindrance exerted on liquid molecules intruding micro-sized pores. This novel concept is exemplified in molecular simulations of a prototypical model system with methanol pervading narrow hydrocarbon or graphene pores. While macroscopic surfaces of both materials show significant wetting propensities on macroscopic surfaces, substantial compression is required to wet molecular-sized pores barely accommodating a monolayer of liquid molecules. The observed $O(10^3)$ bar intrusion pressures secure energy densities exceeding those of advanced supercapacitors. Because of small pore diameters and favorable wall-liquid interactions, the intrusion-expulsion cycling avoids pronounced

activation barriers to evacuation and concomitant cycle hysteresis, common in conventional experiments involving water in hydrophobic capillaries. Using open ensemble (Grand Canonical) Monte Carlo sampling, we determine the range of porosities leading to a highly reversible energy storage/recovery operation and identify material characteristics leading to optimal energy-storage and power capacities in molecular spring devices in pragmatic contexts.

Abstract Name: Expanding Vocal Literature: An Inclusive Linguistic Database

This project aims to address the lack of linguistic diversity in vocal music studies within U.S. universities and conservatories. Within the classical vocal music curriculum, languages such as French, German, Latin, and Italian dominate the languages in vocal music that are performed. This project provides students, faculty, conductors, and vocal coaches with resources for a broader range of languages in classical vocal music. This is done by creating an easily accessible online database that contains over 744 lyric diction resources, including International Phonetic Alphabet transcriptions, audio and visual recordings, and translations in a variety of different languages, along with 131 additional materials such as practice guides, organizations, competitions and journals. The goal of this database is to broaden students' repertoires by providing easy access to a wider range of repertoire from different cultural backgrounds and languages that are not taught in school curriculums. These resources are available globally, allowing vocalists worldwide to access them. Ultimately, this project will increase representation in music education, offering a centralized location for learning materials that can enrich a more inclusive approach to vocal repertoire.

Abstract Name: Optimizing Game AI: Designing a Unified Framework for Efficient Agent Behavior in Unreal Engine

The gaming industry, one of the largest globally, has seen technology advance significantly over the past 50 years (J.P. and Wolf). However, despite these advances, one aspect of video games has not progressed at the same rate: artificial intelligence (AI). Current gaming AI frameworks include Hierarchical State Machines, Goal Oriented Action Planning, and Behavior Trees. These frameworks may be combined to implement AI mechanics in video games, or used independently to power an AI agent, an autonomous decision-making entity that responds to game states. Although effective, each approach has drawbacks that complicate the use depending on the game's type or genre. These challenges, among others, lead to the central question guiding my research: How can existing AI frameworks be leveraged to build a new framework that streamlines, and optimizes the process of building an AI agent for designers and developers? Recent research (Iovino et al.) emphasizes their application across various fields. However, little attention has been given to its specific use in game development. My research aims to address this gap. This study hypothesizes that, in matched Unreal instances, the proposed AI framework reduces CPU cost, decision latency, and maintains or improves task completion rates relative to baseline frameworks, while enabling designers to implement equivalent behaviors

in less time and with higher perceived usability. Employing experimental and design-based research in Unreal Engine, iteratively designing, and refining a prototype using C++ based on a new architecture where a “Commander” AI agent handles complex behavior and issues simplified instructions to simpler AI agents, enabling these agents to perform complex tasks without incurring high computational cost. This framework is evaluated against alternative frameworks using the metrics listed above. This research offers a practical tool for game developers to create efficient adaptable AI agents with reduced computational cost.

Abstract Name: A study of hole doping in Kagome metal KV3Sb5

Kagome metals consist of corner-sharing triangular lattice points, which give rise to unique electronic properties such as superconductivity and charge density waves. KV3Sb5 is a recently discovered 2D superconductor with superconducting transition temperature, T_c , of ~ 1 K. In order to study the effect of hole doping on KV3Sb5, we synthesized KV_{2.85}Ti_{0.15}Sb5 compound and then performed x-ray diffraction (XRD) and magnetization measurements. The XRD shows that the Ti-atoms substitute the V-atoms on the kagome lattice sites, preserving crystal symmetry. Because Ti has fewer valence electrons than V, this substitution introduces hole doping into the parent compound. Due to the larger radius of the Ti-atom, we observe that the lattice unit cell expands slightly in KV_{2.85}Ti_{0.15}Sb5 compared to the parent compound. The magnetic measurement data reveal that the T_c elevates in KV_{2.85}Ti_{0.15}Sb5 compared to the parent compound. Through the magnetic data, we also discovered that the T_c suppresses with the applied magnetic field. Our study demonstrates significant insight into the effect of Ti-doping on the crystal structure and magnetic properties of KV3Sb5.

Abstract Name: An Analysis of the Influence of Early Modern Fairy Folklore on the Salem Witch Trials

In 1692 a flurry of witchcraft accusations and executions tore through the village of Salem, Massachusetts, leaving behind a dark legacy that still captures the American imagination to this day. However, unbeknownst to both the Puritans of Salem and the modern public, the episode carried with it the traces of a much earlier tradition: the belief in fairies. This paper, originally submitted for my senior capstone on witches, begins exploration into the effects of early modern fairy folklore on the Salem witch trials. Examining this connection, which has been previously neglected by existing scholarship, highlights the ways in which British and Scottish folk beliefs evolved through both the Reformation and passage to the New World. Uncovering how fairy beliefs presented themselves in the Salem witch trials required analysis of several period documents. The Secret Commonwealth of Elves, Fauns, and Fairies, by seventeenth century Scottish clergyman and theologian Robert Kirk is perhaps the best source on popular belief of fairies in Great Britain. The writings and sermons of early modern Puritan scholars such as William Perkins and Richard Baxter were used to determine prevailing Puritan belief on fairies in the years leading up to the Salem trials. The Salem

interrogation transcripts themselves show that many of the accusations and confessions line up with traditional folk beliefs surrounding fairies, including animals, spirits, and unusual creatures magically assisting the witch in exchange for blood or other rewards. Even though the term “fairy” is not specifically recorded in any of the Salem trial documents, the language and content of the accusations are otherwise consistent with trials in England and Scotland which do specifically name fairies as the culprit.

Abstract Name: Impact on Diabetes Outcomes: Evidence from Affordable Care Act Medicaid Expansion

Before the Affordable Care Act expansion in 2014, Medicaid program primarily covered pregnant women, low-income families with children, and elderly and disabled people with Supplemental Security Income (SSI). The expansion extended coverage to most of the adults up to 138% Federal Poverty Level (FPL), and it was adopted by 27 states in 2014 and by 2021, it increased to 39 states (including DC). Past literature provided evidence that this led to a significant increase in the total Medicaid coverage and consequently a decrease in the total number of the uninsured individuals in the expansion states. According to CDC, among chronic conditions, Diabetes is one of the leading causes of morbidity and mortality in the US. Access to health care is most essential to stay healthy for a diabetic person. With high cost of supplies, medication, education, and medical care to manage diabetes, affordable and adequate health insurance is imperative. This paper examines the impact of the Affordable Care Act (ACA) Medicaid Expansion on diabetes diagnoses, and its management to prevent health complications caused by diabetes. Employing a difference-in-differences framework, we exploit the variation in the eligibility caused by the ACA expansion to compare the changes in diabetes outcomes in the expansion states (treatment group) with the non-expansion states (control group).

Abstract Name: Advancements in Spacecraft Trajectory Generation through Matrix Decomposition Techniques

The Circular Restricted Three-Body Problem (CR3BP) is renowned for its intricate and chaotic dynamics, leaving it without a closed-form solution. In this poster, we introduce an innovative approach to determine spacecraft trajectories within the CR3BP framework using matrix factorization techniques. We formulate a matrix equation where the right-hand side vector is constructed from the spacecraft's position and velocity data, while the coefficient matrix is derived from the spacecraft's temporal data. Subsequently, we apply several matrix decomposition techniques, including modified Gram-Schmidt, the Householder technique, and Givens Rotation, to analyze the coefficient matrix and derive the spacecraft trajectories. Finally, we evaluate the execution time and floating-point operations (FLOPS), alongside the numerical stability of each method, to obtain a quantitative comparison of the proposed techniques.

Abstract Name: How Breast Cancer Cells Hide: The Role of ZMYND8

Breast cancer is among the most diagnosed cancers and leading cause of death in women. In this regard, we are studying ZMYND8, a multifunctional protein that plays a crucial role in regulating genomic stability and the innate immune response in breast cancer cells. We are investigating the phenotypic effects of decreasing ZMYND8 expression on the aggressiveness of breast cancer cells. Studies show ZMYND8 suppresses DNA damage preventing micronuclei formation, thereby inhibiting immunostimulatory signaling pathways in breast cancer cells preventing recognition by the immune system. Loss of ZMYND8 leads to increased DNA damage, triggering activation of DNA sensors and downstream immune responses. As a result, T-cell infiltration into the tumor microenvironment is enhanced, enabling an effective antitumor immune response significantly reducing tumor growth. These findings pinpoint ZMYND8 as a negative regulator of antitumor immunity and suggest that it plays a key role in the progression of breast cancer. We plan to reduce ZMYND8 expression in breast cancer cells using a small interfering RNA (siRNA)-mediated knockdown method and confirm knockdown efficiency by quantitative PCR (qPCR). Once confirmed, we will evaluate its effects by performing colony formation and transwell migration assays to assess growth, migration, and invasion abilities of breast cancer cells. Additionally, we expect the aggressiveness to diminish alongside the already reported reduction in growth. Targeted pharmacological inhibition of ZMYND8 could therefore represent a novel therapeutic strategy to reactivate the body's own immune defense against tumor cells. Combining ZMYND8 inhibitors with established immunotherapies or chemotherapies could achieve synergistic effects and improve the efficacy of existing treatment approaches. Although these findings are currently based primarily on preclinical studies in cell and animal models, they offer promising perspectives for developing new immunotherapies. Further experimental and clinical investigations are needed to fully validate the potential of ZMYND8 as a therapeutic target in breast cancer treatment.

Abstract Name: Continued Enrichment of Students in Action: Fostering an Engaged Community Through Grades 6-12 School Programming

As students in Dr. Jason Ware's TREKS research generator, we have been continuing the goals of the educational service-learning program, Students in Action (SIA). This program strives to connect grades 6-12

students with service-learning educational content and opportunities for projects. SIA began as a part of the national service organization Multiplying Good, which went bankrupt in August 2024. In light of this, we have assumed Multiplying Good's duties to continue working with the local schools which have partnered with Purdue University previously. The student-led conferences have been received positively, as they have allowed us to continue broadening these schools to new avenues of community engagement. The content in these conference sessions provides students with guidance to get involved in the community, and leaders' knowledge of the local area creates more personalized, relevant examples. The session leads are also significantly younger than the leaders of the conferences under Multiplying Good, so they are capable of relating to the attendees and fostering stronger learning and motivation. Outside the conferences, we prioritize coordinating with our partner schools to send college students to be "coaches." These mentors work alongside the younger students to guide them through proper service-learning initiatives. Since last year, we have hosted two additional conferences. Through these, we have connected students with more opportunities to get involved in their local communities, shown local organizations that students are willing to work, and instilled students with agency to pursue this work. Additionally, we have been able to keep a partner school involved in the program despite having a completely new group of students. Moving forward working with local schools, we aim to refine a standardized model for other universities to implement similar programs. This includes both creating process and planning documentation and brainstorming how to plan without access to substantial monetary backing.

Abstract Name: Gender and Power in the Latin Cartulary of the Abbey of Saint-Amand

This project transcribed a heavily abbreviated, handwritten, 13th-century Latin manuscript and translated it into English to analyze how female religious communities wielded power in the Middle Ages. The Cartulary of Saint-Amand contains contracts primarily detailing the day-to-day managerial life of the abbess, or head, of a Medieval abbey, most notably concerning the lands the abbess bought and the tenants she managed on behalf of the nuns of Saint-Amand. The Cartulary contains the abbey's founding documents and grants from the King of France and the Pope that allow the abbey to operate, and the land contracts within the Cartulary span a timeframe of hundreds of years. By maintaining a historical record of lands acquired, rents owed, and agreements made with tenants, the abbess of Saint-Amand ensured future generations of nuns could continue to wield immense lordly power in their community without challenges from men. Through translation, I found that medieval religious women, despite modern notions of perceived frailty and submission, were extremely successful landlords, greatly expanding their property holdings throughout the early 13th century and establishing a monopoly on profits in medieval Rouen, France. The charters contained in the Cartulary establish that the abbess of Saint-Amand fulfilled the role expectations of male landlords, and her authority was not challenged due to her gender. Translations of the Cartulary also demonstrate that medieval religious women were successful financial managers, with numerous charters establishing that the abbess of Saint-Amand received a vast quarterly income from her tenants. My presentation will highlight the intersection of gender and power in later Medieval France to further disprove modern conceptions of gendered authority in the Middle Ages.

Abstract Name: "Vote for Woman Suffrage and Democracy at Home": Holland, Michigan, and the Fight for Enfranchisement

Michigan women's fight for the ballot began nearly 75 years before the 19th Amendment guaranteed American women the right to vote. Despite facing consistent opposition, women slowly gained a position in the political sphere, often through social activism and discussion groups. In Holland, Michigan, suffrage activism began in 1912 and continued through 1918, when women gained the right to vote via a state referendum. Joining the work of the Holland Equal Suffrage Association, a group of Hope College girls formed their own suffrage chapter in 1917. Although meeting minutes did not survive and, therefore, gaps remained in the narrative, it was possible to reconstruct the movements of Holland's suffrage clubs as well as their connection with other Michigan suffrage organizations and speakers through letters, yearbooks, activist pamphlets, and newspapers. Suffrage gained a relatively large base in Holland, which was surprising given the town's conservative religious foundation. At the same time, as women gained education and workplace opportunities, these organizations reflected the principles of the Progressive Era New Woman, who involved herself in numerous women's groups and reform efforts.

Abstract Name: Adoption of Artificial Intelligence in Management: A Systematic Review of Organizational Use and Employee Perspectives

This study examines how artificial intelligence (AI) is reshaping managerial work and the perceptions of employees responsible for its adoption. As organizations face rapid technological change, they must continuously adapt their processes and operations to enhance customer satisfaction, maximize profitability, and sustain long-term growth. With the accelerating development and diffusion of AI technologies across industries, there is an increasing need for organizations to provide managers with a clear understanding of how to integrate AI into business processes. Recent research suggests that AI-human augmentation in workflows and decision-making is likely to become standard practice by 2030, highlighting the importance of active leadership involvement in co-creation and implementation of AI systems. Since AI's conceptual emergence in the 1950s and its practical advancement beginning in the 1980s, it has evolved from simple tools such as recommender systems, spam filters, and online advertising among others to advanced generative models capable of processing vast datasets and supporting complex decision-making, in some cases even replacing human labor in specific tasks. These technologies now enable a broad range of organizational applications including risk management, data analytics, recommendation engines, and customer relationship management. While organizations are enthusiastic about the opportunities AI presents, employees are concerned about job displacement and integration anxiety. This study synthesizes research on AI adoption across industries and employee perspectives on its integration and proposes a framework for organizations on how to use AI effectively, safely, and ethically while engaging and upskilling employees to support successful implementation. Keywords: Artificial Intelligence, Organizations, Management, Employee Perspectives

Abstract Name: Reinventing Undergraduate Computing (and All) Research in the Era of AI

Artificial intelligence (AI) is changing the world, and its impacts are particularly pronounced on those with limited experience. AI has significantly reduced the opportunities for recent graduates and interns in a variety of fields, including and perhaps most significantly impacting the computing fields. It also changes the dynamics of undergraduate research. For programs that perform (and are funded for) undergraduate research training, changes are needed to prepare undergraduate researchers for this new environment. For undergraduates funded by research goal-driven funding, the comparative benefit of undergraduate students to AI tools, for various tasks, may drive the reevaluation of undergraduate student research involvement and tasking. This presentation focuses on the opportunities that AI presents and how to take advantage of them. It has three synergistic focuses. First, it discusses what capabilities that AI can offer and how these can displace undergraduate researchers – particularly when funding is not tied to undergraduate researcher training. Then, it discusses how AI tools can enable undergraduate research by aiding and enhancing their learning, increasing their productivity and facilitating increased project scope. Finally, the presentation discusses how AI is changing and is poised to further change the undergraduate research landscape. This presentation will include a discussion and demonstration of a number of AI tools and also cover how they can be used in research. It will also discuss the additional training requirements that use of these tools may require – for both faculty mentors and student researchers. A brief project concept, suitable for undergraduate participants – and placing undergraduate students in leadership roles – will be built during the presentation using AI tools. This will show how the tools can be used to aid research and reinforce and demonstrate the aforementioned three key focus areas. This presentation will provide guidance for faculty mentors and student researchers alike.

Abstract Name: Fraktur in the Fields

Fraktur in the Fields September, 2025 Micron Ink on Paper 22" x 30" Using thin, black lines against a stark white backdrop, this piece utilizes movement and mark-making to elicit imagery, rather than relying on a style of representational depiction more typical in my portfolio. Flowing forms invoke familiar scenes: foliage, cloudy skies, fields. Geometric borders with tassel-like icons are reminiscent of the hoop houses and agricultural plots that mark our nations' open land, or of vintage upholstery to be spotted in domestic spaces. These borders have been compared to various folk art practices, but are Influenced by the folk-art tradition, 'fraktur', of the Pennsylvania-Dutch, early Germanic settlers and immigrants that developed a distinct ethnic identity in southeastern Pennsylvania. My paternal side are all Pennsylvania-Dutch, having come to this land when it still identified as a colonizing entity, before this reality was shrouded behind the label of nation. In the center of the piece, fraktur floral motifs are obscured by the surrounding patterns, a stylistic decision driven by seeing how the construction of whiteness and nationality suppress and erase regional ethnic identities and folk art traditions. This phenomenon is achieved on two fronts: Indigenous cultures are subject to violent assimilation campaigns, more extreme in degree to the cultural coercion settlers, immigrants, and refugees undergo, as all are made to forgo their folk identities in exchange for US nationalism and a ruthless construct of whiteness.

Abstract Name: Site-Specific Lysine Acylation Disrupts Fumarate Hydratase Assembly and Catalytic Activity

Fumarate Hydratase (FH) is a core enzyme in the tricarboxylic acid (TCA) cycle. Metabolic enzymes like FH regulate energy flux within a cell. Once translated, enzymes such as FH undergo post-translational modifications (PTM), such as lysine acylation, which can fundamentally change the enzyme structure and function. This can cause cascading effects on energy production, DNA repair, and tumor growth if uncontrolled. In a line of paraganglioma cancer cells with succinate dehydrogenase loss, FH levels and acylation PTM levels were altered. This project aims to uncover the effect of these PTMs on FH structure and function. Two mimetic variants were designed to mimic FH acetylation and succinylation at two corresponding lysine residues (K292 and K230) with two corresponding non-mimetic variants to act as controls. These four variants were subjected to functional kinetics and structural characterization, including limited proteolysis and cross-link mapping, circular dichroism, differential scanning fluorimetry, mass photometry, and protein crystallization. Although the K292 variants show minimal PTM-induced changes in local FH structure, both K292 and K230 variants exhibit significant alterations in oligomerization and catalytic activity. In the presence of a known competitive inhibitor, the charge-conserving controls retain tetramerization similar to unmodified FH, whereas the acetylation and succinylation mimetics show a marked loss of tetramer assembly, corresponding with severely reduced catalytic activity in kinetic assays. The acetylation and succinylation mimetics showed a five-fold and six-fold decrease in k_{cat} compared to their respective charge-conserving controls. These findings demonstrate how FH acylation disrupts structural assembly and catalytic activity, supporting a model in which uncontrolled PTM-driven oligomeric regulation contributes to metabolic dysfunction in cancerous cells.

Abstract Name: Assessing the Relationships Between Strategy Tendency & Mental Rotation Processing Using Eye Tracking

Mental rotation, a subtest of spatial visualization skills, assesses cognitive ability to mentally manipulate multidimensional objects in space. Research has demonstrated a relationship between high performance on mental rotation tasks and success in STEM fields. Mental rotation skills are trainable; individual differences in performance may be dependent on the cognitive strategies used to complete tasks, so understanding strategies is imperative for refinement and expansion of spatial training programs. 46 adults ages 18-24 were recruited to participate in an fMRI mental rotation task with eye tracking. Additional behavioral assessments included a standardized test of mental rotation and a lab-developed mental rotation strategy questionnaire. My research assesses (1) whether the strategies used by participants during mental rotation tasks correlate with performance metrics, and (2) whether strategy differences relate to eye movement patterns. Eye movements were not found to be valid predictors of strategy, nor were strategies predictors of performance. Analyses grouped by rotation condition demonstrated a significant increase in eye fixations with increasing angular disparity, but a decrease in task accuracy. When examining a participant's entire in-scanner run,

however, fixation counts and reaction times were found to decrease significantly over time, while accuracy increased. These findings indicate that performance improvements and corresponding eye movements may be best explained by learning, emphasizing repeated practice as an integral component of spatial visualization training. Future research may benefit from analyzing strategy tendency by degree of angular disparity to identify subtler trends in eye movement behavior and pinpointing the role of working memory in task execution.

Abstract Name: SEX DIFFERENCES IN PHYSICAL ACTIVITY IN ADOLESCENTS WITH OBESITY AS ASSESSED BY WRIST-WORN ACCELEROMETRY.

Physical activity (PA) has been shown to differ between male and female adolescents, with males typically averaging higher daily PA. However, this difference may be complicated by weight status. The purpose of this study was to compare objectively measured PA in male and female adolescents with obesity using wrist-worn accelerometers. Treatment-seeking adolescents (N=69; 43 females, 13.7±1.2 yrs; 98.3±1.8%ile for BMI) wore an Actigraph GT3X for 7 consecutive days. The GGIR package in R was utilized to determine time spent inactive; engaged in light, moderate and vigorous activities (5 sec epochs); and engaged in moderate-vigorous PA (MVPA) (1-min and 5-min epochs). Associations between PA and weight status were assessed with Pearson-Product Moment Correlations. Mann-Whitney U tests were used to compare differences between male (M) and female (F) groups on each PA variable. Age, weight, or BMI were not significantly different between groups. Significant ($p<0.05$) negative relationships were observed between all PA measures and weight status in both groups along with a significant positive relationship between time spent inactive and weight status. Inactive time (M-758.4±87.2; F-759.5±80.9 min) and time in light (M-168.0±42.2; F-166.2±42.6 min/d), moderate (M-50.5±22.7; F-44.9±18.6 min/d), and vigorous (M-5.5±5.0; F-3.2±3.1 min/d) PA did not differ between groups. However, significant differences were observed in MVPA when analyzed in more sustained 1-min and 5-min epochs for all days and weekdays, but not weekend days, with males averaging ~12 min/day more MVPA (M-43.2±23.0; F-31.3±21.8 min/d). In conclusion, male adolescents with obesity accumulated more daily MVPA when measured in sustained periods, particularly on weekdays. These findings highlight differences in activity patterns that may inform tailored strategies to promote PA in adolescents with obesity.

Abstract Name: Maternity and Self-Fashioning: Vigee Le Brun at the Threshold of Revolution

This paper reinterprets Élisabeth Vigée Le Brun's Self-Portrait with Her Daughter Julie (1789) as a calculated

act of self-fashioning that fuses maternal virtue with artistic authorship on the eve of the French Revolution. Long sidelined as merely sentimental, the painting—exhibited weeks before the artist’s October flight from Paris—deploys a Madonna-coded visual language (triangular composition, Raphael inflections, chromatic pairing of red and blue) to claim moral respectability and artistic lineage while deliberately omitting studio props that would conventionally index her profession. Through close looking (following the practice modeled by T. J. Clark) and contextual readings of *Souvenirs*, the essay situates the work within the competing 18th-century constructions of womanhood: Enlightenment prescriptions of “natural” motherhood (Rousseau) and the public culture of the Salon and Académie that alternately elevated and constrained women artists. It argues that specific pictorial decisions—the exposed shoulder, the low-tied red sash that draws the eye to the lap/womb, and Julie’s forward, claiming embrace—produce a productive ambiguity, at once intimate and strategic, that recasts maternity as the very site of authorship, reputation management, and survival. By aligning herself with sacred prototypes while meeting d’Angiviller’s neoclassical turn in taste, Vigée Le Brun fashions a public person capable of withstanding scandal and political volatility. The result is not a retreat into domesticity but a bid for legacy: an image that continues to read as tender and tactical, personal and public, across revolutionary thresholds and into our present.

Abstract Name: Performing Gender & Power: Donatello's David and Judith & Holofernes

Donatello has long been celebrated as a master of Renaissance sculpture, but two of his most enigmatic works—the bronze David (c. 1440) and Judith and Holofernes (c. 1457–64)—resist stable interpretation. At first glance, they appear to embody opposite ideals: David is nude, delicate, and serene in victory, while Judith is veiled, composed, and violent in action. Yet when read through Judith Butler’s theory of gender performativity, these sculptures emerge not as fixed embodiments of masculine heroism or feminine virtue, but as staged performances of unstable roles. This paper argues that Donatello’s David queers conventional masculinity by presenting triumph through softness, nudity, and aestheticized beauty rather than brute force. In Butlerian terms, his heroism is a costume—performed through stylized gestures that reveal masculinity as artifice. By contrast, Judith and Holofernes performs chastity and civic virtue as equally unstable, cloaking aggressive power in modest attire. Judith’s poised, veiled body simultaneously enacts violence and virtue, exposing the fragility of gendered categories. Situating these sculptures in their Medicean context, I examine how their civic display and later displacement illuminate the cultural labor required to stabilize gendered power. The removal of Donatello’s ambiguous David and Judith from prominent Florentine sites—replaced by Michelangelo’s colossal, hyper-masculine David—underscores Butler’s claim that gender must be endlessly reiterated to appear “natural.” Donatello’s originals remind us that identity is always theatrical, contingent, and vulnerable to collapse. By bridging Butler’s late-20th-century framework with Quattrocento visual culture, this study reveals how Renaissance art can be read not simply as reinforcing patriarchal norms but as staging their fragility. Donatello’s David and Judith anticipate contemporary conversations in feminist and queer theory, demonstrating that gender has never been a given—it has always been performance.

Abstract Name: The p53/PINK1 Complex in the Noncanonical Mitophagy Pathway Secretory Mitophagy

Cells rely on mitochondria for energy, but these organelles are highly sensitive to stress. When mitochondria become damaged, they are typically removed through mitophagy, a pathway that delivers dysfunctional segments to the lysosome. When this system becomes overloaded, cells can shift to an alternative pathway called secretory mitophagy, wherein whole damaged mitochondrial fragments are packaged into extracellular vesicles (EVs) and released. This export mechanism supports survival under oxidative stress by stabilizing mitochondrial function and limiting apoptosis. This study examined how an activated form of the tumor-suppressor protein P53 (phosphorylated at Ser392) behaves under conditions that promote secretory mitophagy. Mitochondrial stress was induced in two cancer cell lines using CCCP, followed by collection of EVs and cell lysates to assess mitochondrial stress responses and P53 redistribution. Across western blotting, immunofluorescence, and immunoprecipitation analyses, stressed cells consistently redistributed activated P53 from the nucleus to the cytoplasm and mitochondria, where it was packaged into EVs alongside PINK1 and other mitochondrial markers. EVs collected under stress showed strong co-enrichment of P53, PINK1, and mitochondrial proteins, supporting selective incorporation during secretory mitophagy. Consistent with this redistribution, nuclear P53 activity decreased as CCCP concentrations increased. Because nuclear P53 normally represses oncogenic transcription factors, Nanog expression was evaluated as well. Nanog remained elevated when activated P53 was exported, consistent with a reduction in P53-mediated transcriptional suppression. Together, these results support a model in which secretory mitophagy removes activated P53 from the nucleus and packages it into EVs. This export weakens P53-dependent transcriptional control and may contribute to a shift toward a more proliferative, cancer-promoting cellular state during high mitochondrial stress.

Abstract Name: Undergraduate Research Course Development: Exploring Learning Outcomes, Methods of Assessment and Instructional Strategies

The purpose of this presentation is to highlight the development of an Honors College undergraduate research course by the Research and Learning Services Department at Oklahoma State University. Together, we will explore the challenges and successes of developing an authentic undergraduate research course specifically designed to prepare honors students for future thesis research projects. This presentation will explore critical skills in course development including; creating learning outcomes, identifying authentic methods of summative and formative assessment, and the implementation of instructional strategies that align with the overall purpose and goals of an undergraduate research course. Participants will explore the importance of developing learning outcomes that align with the mission of a department or college and accurately reflect degree program requirements. Additionally, we will differentiate between formative and summative assessments through a variety of assessment options that can be tailored to different learning environments. Finally, we will deconstruct important instructional strategies such as direct/indirect instruction as well as problem/project-based methods of instruction. The overarching goal of this presentation is to showcase

options in course design that promote student creativity, mentor-student synergy, and focus on a dedication to cultivating a vibrant research culture at the undergraduate level.

Abstract Name: Establishing a Baseline for Argentinian Thread-Waisted Wasps: A Species-Level Checklist of Sphecidae sensu stricto

Apoidea, or apoid wasps, encapsulate a wide range of morphologies, behaviors, and essential ecological roles within the order Hymenoptera, yet many groups remain poorly documented in museum collections and online databases. Recent projects at the American Museum of Natural History (AMNH) note that Argentina may host more than 600 apoid wasp species, including a substantial number with type localities inside the country. Within Apoidea, a striking lineage emerges: the thread-waisted. Thread-waisted wasps (Sphecidae sensu stricto) are notable for their elongated waists, sculptured bodies, and vibrant colors, which make them both recognizable and taxonomically intriguing. To examine and clarify existing checklists of this remarkable family of wasps, we compiled the first species-level checklist of Argentinian Sphecidae s.s. We employed a comprehensive approach, utilizing multiple databases such as museum collections, GBIF, iNaturalist, regional catalogs, and taxonomic literature. Species supported by only one source or showing inconsistent information were set aside for further review, and synonymies were checked to reduce any redundant records. During this process, several AMNH species appeared to lack any formally documented record for Argentina; these require final morphological confirmation but suggest gaps in current country-level checklists. Overall, at least 70 unique species have been identified in this checklist. This project enhances AMNH digitization and checklist efforts by combining digital biodiversity records with the direct use of physical specimens. The resulting dataset updates species presence records, highlights areas of originality of Sphecidae s.s. within Argentina. These key findings support ongoing research on thread-waisted wasps in South America and identify several groups where additional collecting and verification would be particularly advantageous, encouraging continued exploration and study.

Abstract Name: Malawi Hearing Screening Dome

Hospitals and maternity wards in Malawi face frequent exposure to high environmental noise levels which poses a challenge when conducting sensitive tests such as hearing tests. These tests are imperative during early auditory development in infants, sound interference can mislead the signal and give inaccurate results. Without proper diagnosis, infants receive incorrect help, delaying critical stages of speech and cognitive

development. Caregivers in the region lack financial and practical access for solutions that can be safe, effective and sensitive. As of right now Malawi does not have the technology for hearing tests nor a conducive environment to screen these babies. Our solution is to develop a low-maintenance, affordable, acoustically insulated head dome for a built-in newborn hearing screening system to test without outside noise interference. The dome has to account for the size and fragility of all newborn heads, sterilizability for repeated use, have adequate ventilation without sacrificing protection from ambient noise, and must reflect similar accuracy to common methods used by other developing nations. To design this helmet we used SolidWorks to create a model that worked around the clearance of general infant head measurements. Moreover, we were able to compartmentalise the electronics to get accurate signals and data. We also tested preliminary designs of noise canceling systems by integrating ANC methods. When designing our models, we wanted to actively keep the ethics of people in Malawi in mind. Our goal for this technology is for it to eventually be distributed throughout every hospital and maternity ward in Malawi, and further shed light on the importance of hearing screening in babies and access to it.

Abstract Name: How Mentors Practice Empathy: Faculty and Graduate Approaches to Fostering Psychosocial Support, Belonging, and Science Identity in First-Generation and Low-Income STEM Undergraduate Researchers

Mentoring relationships are considered an essential component of successful undergraduate research program models. Their transformative impact is especially salient for students from diverse backgrounds, such as first-generation and low-income students pursuing STEM degrees, who often encounter challenges related to belonging and science identity that can hinder persistence in STEM fields. While literature highlights the importance of empathy in meeting the needs of culturally diverse learners, far less is known about how empathy operates within research mentoring relationships. The present study focuses on how mentors articulate and demonstrate empathy within their relationships with students. Using thematic coding of transcripts from 15 faculty interviews and two graduate mentor focus groups, this qualitative study investigates how empathy took shape within research mentoring relationships. Program evaluations revealed that these mentors had been successful in supporting belonging and science identity in first-generation, low-income STEM students during a summer-long intensive research experience. Accordingly, it is anticipated that key psychosocial elements such as cognitive, affective, and action-oriented empathy, will surface in the analysis. Insights from a companion analysis grounded in Self-Determination Theory (SDT) suggest that meaningful emotional connections are central to these mentoring relationships, providing a theoretical basis for anticipating that distinct empathy dimensions will emerge in the data. The results of this study are expected to contribute to a clearer understanding of how empathy functions as a psychosocial mechanism within undergraduate research mentoring and to inform future program design and culturally responsive mentorship.

Abstract Name: USRP Prototype to Enhance Analytic Capabilities in Dual-End Logging

Software-defined radio suites, such as GNU Radio, face challenges in debugging live digital communications because feedback and help are often limited, making errors hard to identify, especially for first-time users. To address this issue, we prototype a Universal Software Radio Peripheral (USRP) with a GNU Radio File Transceiver system that uses Binary Phase-Shift Keying (BPSK) modulation and a wrapper application for data loss detection and analysis via dual-end logging. This system aims to streamline experimentation with the GNU Radio testbed, support efficient parameter control, reduce manual data collection, and provide users with fast, helpful analysis. BPSK modulation and demodulation ensure reliability even in noisy environments, and a wrapper application provides a user-friendly interface for easy adjustment of key transmission variables. The wrapper application allows users to adjust transmission variables via a simple Graphical User Interface that takes user input and configures GNU Radio appropriately before starting the transmission. The application later generates detailed transmission logs that capture the user's variable settings, file data, and transmission timestamps. Developed logging functionality assists the user in identifying issues within the GNU Radio file transfer system and supports the analysis of data loss, transmission reliability, and the effects of the parameterized settings. Our current implementation provides simplified user configuration and transmitter-side logging. In future development, we aim to include receiver-side logging for data-loss diagnostics, the return of information from the receiver, and AI-enabled instant suggestions to both ends.

Abstract Name: From Clinical Interaction to Socioecological Environment: Belongingness in Healthcare for Transgender, Nonbinary, and Gender Diverse Individuals

Purpose: To gain a holistic understanding of the healthcare experiences of transgender, nonbinary, and gender diverse (TNG) individuals by using a belongingness framework, in order to elucidate the interaction between structural, interpersonal, and intrapsychic factors. Background: TNG individuals have adverse healthcare experiences characterized by discrimination, misattribution, misinformation, and structural barriers. They also report having insurance delays, extended wait times, and difficulty finding an appropriate provider for gender-affirming interventions. Furthermore, accessing healthcare is limited by insurance coverage, and the affordability and availability of care. TNG individuals, doctors, nurses, and allied health professionals have also noted the importance of education on this population. Previous studies have covered the structural and interpersonal factors impacting the healthcare experiences of TNG individuals, and less research has focused on intrapsychic factors. Additionally, no studies have evaluated the dynamic interplay between these factors under a unified framework. Methods: Using transcripts from a previous study on the healthcare experiences of TNG individuals, thematic analysis is performed to identify how a sense of belonging is constructed in a healthcare context. Transcripts are coded using Dedoose, and prominent themes are subsequently identified. Results: Provisional findings for this study include insurance as a facilitator and barrier, allyship increases belonging, and barriers lead to TNG individuals seeking alternate forms of care.

Abstract Name: Unveiled: Exploring Purity Culture, Gender, and Well-Being in Global and National Contexts Within and Beyond the Eastern Orthodox Church

Purity culture, which describes a set of theologically conservative values about sexuality that mandates strict sexual abstinence until heterosexual marriage, can evoke fear and shame in those who fail to comply. While extensively studied within evangelical contexts, the presence and impact of purity culture within Orthodox Christianity remain largely unexplored. This study investigated the relation between purity culture endorsement and well-being across 18 countries along two sets of cultural value dimensions: Traditional vs Secular-Rational, and Survival vs Self-Expression using World Values Survey data ($N = 3,486$; $M_{age} = 21.84$ years, range = 18 to 25 years; 56% female), and additional data from American Eastern Orthodox participants ($n = 48$; $M_{age} = 21.10$ years; 66% female) and non-Orthodox participants ($n = 318$; $M_{age} = 21.97$ years, 49% female). As hypothesized, countries higher in Traditional and Survival values demonstrated markedly stronger endorsement of purity culture [$F(2, 3446) = 1463.89$, $p < .001$, $\eta^2 = .459$]. Well-being did not differ significantly across country groups high, medium, and low in Traditional and Survival values [$F(2, 3483) = 0.001$, $p = .99$]. Mean purity culture scores did not significantly differ between American Orthodox Christians and non-Orthodox participants [$F(1, 358) = 0.33$, $p = 0.57$]. Within the Orthodox sample, purity culture was not significantly correlated with depression-anxiety symptoms or objectified body consciousness. Together, these findings suggest that while purity culture endorsement varies strongly by national cultural values, its expected detrimental relation to well-being was not consistently observed. Results contribute to a nuanced understanding of purity culture as a culturally embedded belief system whose psychological impact may differ across religious and sociocultural settings.

Abstract Name: Synthesis of Dynamic Polymers with Covalently Integrated Hypervalent Iodine (III) and Bismuth (V) Functionalities

Polymers are macromolecules made up of repeating monomer units linked by covalent bonds. They are the fundamental building blocks of many natural and synthetic materials and are widely utilized for their versatility across a broad spectrum of applications, including plastic bags, adhesives, PVC pipes, etc. My research focuses on dynamic polymers, materials that can repair themselves and reorganize after damage. Unlike traditional plastics, these polymers contain special bonding units made from hypervalent iodine and bismuth, elements that can form bonds which easily break and reconnect. This reversibility is what gives the materials their self-healing and shape-changing properties. I will study how light or heat can switch these polymers between a flexible, self-healing state and a more stable, long-lasting form. To create these materials, I will use chemical reactions, such as ligand exchange and the condensation of iodosylbenzene with dicarboxylic acids, that build the polymer chains and introduce the iodine and bismuth units that enable this dynamic behavior. By investigating how these polymers can repeatedly form and break bonds when certain chemicals are present, this research aims to allow for the development of self-healing and regenerative materials with advanced applications in material science, such as reactive coatings, adhesives, etc.

Abstract Name: Using “Emotional” Music to Engage Neural Pathways Involved in Cognitive Empathy for Use in Music Therapy for Adolescents with Autism

Empathy is crucial to everyday interactions; the ability to understand and aptly react to the internal states of others is essential to living a fulfilling and successful life. Deficits in cognitive empathy have been heavily linked to Autism Spectrum Disorder (ASD), so there have been numerous studies focused on empathy remediation in individuals with ASD. Many of these studies use music therapy to accomplish this goal, yet not much is known about what kind of music is most effective at developing empathy. Peer reviewed studies on the music preferences of empathetic individuals, the neural pathways engaged by listening to music and social cognition, and the effectiveness of other arts and music based therapy in empathy remediation were analyzed to understand how “emotional” music may be effective at improving empathy in individuals with ASD. The findings suggest that “emotional” music may be able to increase cognitive empathy in adolescents with autism by strengthening the neural pathways used in social cognition, as well as more effectively engaging emotional mirroring in the listener. This paper aims to discuss how due to “emotional” music’s effectiveness at increasing cognitive empathy, music therapy interventions with the intention of increasing empathy in adolescents with autism may benefit from focusing on engagement with “emotional” music. Future studies may expand upon this idea by comparing changes in empathy in participants after “emotional” music therapy and other forms of music or arts-based therapy.

Abstract Name: The Impact of Exam Wrappers on Metacognition, Self-Referential Processes, and Academic Performance in Undergraduate Human Anatomy students.

Background: Prior research demonstrates high attrition rates and low student engagement among Human Anatomy and Physiology students. Students in these courses face poor academic performance and low pass rates. Exam wrappers are survey-based tools used to prompt student reflection on concepts such as test preparation, study strategies, and exam performance. By fostering metacognition, exam wrappers can influence how students approach course material, potentially improving student outcomes in Anatomy courses. Purpose: This study investigates whether exam wrappers promote self-reflection, growth mindsets, study habits, and reduced test anxiety and then examines how these factors can impact exam performance. Methodology: Participants were Human Anatomy students who completed surveys assessing self-reflection, growth mindsets, study habits, and test anxiety. We employed a quasi-experimental pretest-posttest design, with students assigned to either an intervention or a non-intervention control group based on their course sections. Surveys were administered at Westminster and Weber State Universities after the first and final exams, with only the treatment group receiving the exam wrappers. Participation was voluntary, and students who completed the exam wrapper could take new questions on unmastered concepts, earning points toward their final grade for correct answers. Implications: The study highlights the possible impact of self-referential capabilities (e.g., growth mindsets and study habits) in a test-taking environment. Findings from this study

may inform research on how self-referential capabilities impact student test performance and how providing the opportunity to relearn and retest after reflection may positively affect student performance.

Abstract Name: Nitro-Modified Curcumin Analogs Suppress STAT3 Signaling and Inhibit Glioblastoma Stem Cell Growth

Signal Transducer and Activator of Transcription 3 (STAT3) is frequently overactivated in cancers, including glioblastoma (GBM), where its dysregulation is associated with aggressive disease and poor patient survival. STAT3 supports tumor progression by promoting proliferation, resistance to apoptosis, maintenance of cancer stem cells, and immune suppression. Although numerous STAT3 inhibitors are under preclinical and clinical evaluation, none have yet achieved FDA approval. GBM remains a highly lethal brain cancer with limited therapeutic options, underscoring the need for new targeted treatments. Nitro-containing compounds, known for their strong electron-withdrawing characteristics, are emerging as potential anticancer agents. A library of 41 nitro-containing chalcones and cyclic C5–curcumin derivatives was synthesized and screened for cytotoxicity in three glioblastoma stem cell (GSC) lines. Compounds were tested at concentrations ranging from 0.1 to 10 μM , and cell viability was assessed after 72 hours using an MTS assay. Neurosphere-forming assays were conducted to evaluate effects on GSC self-renewal. Western blotting was used to examine alterations in STAT3-related signaling pathways. SwissDock modeling was employed to predict compound interactions with STAT3. More than half of the synthesized molecules demonstrated average IC_{50} values ≤ 10 μM in GSCs, and four exhibited IC_{50} s in the low-nanomolar range. Among them, Compound 31, a nitro-substituted cyclic C5–curcumin analog, displayed the strongest activity, with an average IC_{50} of 0.76 μM , outperforming WP1066 (IC_{50} 2.12 μM), a clinical-stage STAT3 inhibitor. Compound 31 markedly decreased neurosphere formation, reduced STAT3 phosphorylation, and suppressed downstream gene expression. Docking studies revealed predicted binding to STAT3's SH2 domain, a key site for activation. Nitro groups represent highly effective functional moieties capable of inducing cancer cell death through diverse mechanisms. Several potent nitro-based molecules were identified, with Compound 31 emerging as a promising direct STAT3 SH2-domain inhibitor and a potential therapeutic candidate for GBM.

Abstract Name: What Shouldn't Decay: Uncomfortable Rot in Modern Depictions

The purpose of my project, "What Shouldn't Decay," is to make you uncomfortable, not with gore or violence, but with a disruption to an ethical and natural order. It examines how and why these modern depictions of unnatural death and decay evoke illicit psychological and moral discomfort. Real instances, such as pigs consuming human flesh, the Mexica biohazard incident, and creative expressions like the uncanny music series by The Caretaker and digital horror by the developer Yames, cause disorientation to your senses. This analysis argues that these depictions expose the psychology and importance of death through the revulsion of the senses. Taking an interdisciplinary approach combining art theory, cultural analysis, and psychology, I trace how people in our contemporary time have transformed physical rot into unthinkable spectacles. The study explains how sensory dissonance, uncanny imagery, distorted sound, and the smell of slow decay, caused solely by human influence, force a discomfort with mortality onto audiences. It argues that our unease arises not only from physical disgust but also from recognizing in these decaying images our own fragility and guilt. Ultimately, this "uncomfortable rot" is existential anxiety about death itself, paired with social disgust of the unthinkable.

Abstract Name: Beyond the Classroom: The Role of Socioeconomic Status in English Grades

This study examines whether socioeconomic status (SES) affects English grade point averages (GPAs) among African American high school students. SES, which includes factors like family income, education, and occupation, is known to influence academic performance, especially in communities affected by racial and economic inequality. Using data from the High School Longitudinal Study of 2009_2016 (HSL:09), this research focuses on students at the lowest and highest SES levels, totaling 769 African American participants. To analyze differences in English performance, this study used an independent samples t-test to compare English GPAs between the two groups. The results show clear disparities: students in the lowest SES group had an average English GPA of 1.97, while those in the highest SES group averaged 2.66. This difference is statistically significant ($p < .001$), meaning it is very unlikely to be due to chance. These findings suggest that higher SES African American students tend to perform better in English, likely due to greater access to academic and cultural resources. Grounded in Bourdieu's cultural capital theory, the study highlights how advantages outside the classroom can shape academic outcomes. Overall, the research emphasizes the need for increased support for low-SES students to help reduce achievement gaps.

Abstract Name: JNK Knockdown Alters Cytokine Expression in CAR-T Cells

Chimeric Antigen Receptor (CAR) T-cells are genetically modified T cells engineered to fight cancer cells. While a promising cancer treatment, CAR T cells show limited efficacy against ovarian cancer, partially due to the immunosuppressive tumor microenvironment (TME), which includes immunosuppressive cytokines that diminish CAR-T cell activity. Our research aims to improve CAR-T cell effectiveness by optimizing CAR-T cell cytokine production, which may impact the overall cytokine environment of the TME. We hypothesize that controlling c-Jun N-terminal Kinase (JNK) signaling in CAR-T cells may improve anti-tumor functionality through alteration of CAR-T cell cytokine production. We developed a lentivirus vector containing short-hairpin RNA (shRNA) to knock down JNK in CAR T cells. Human Epidermal Growth Factor Receptor 2 (HER2) targeting CAR-T cells with and without JNK knockdown were produced from human peripheral blood T cells to evaluate the role of JNK signaling in CAR T cell production and functionality. CAR-T cell differentiation status after production was assessed by flow cytometry. CAR-T cell cytokine production was then tested by Enzyme-Linked Immunosorbent Assay (ELISA). JNK knockdown in CAR-T cells did not alter the total expansion, CD4:CD8 ratio, or differentiation status of CAR-T cells during production. JNK knockdown reduced the production of several cytokines (IL-10, IL-4, IL-5, IL-2) by approximately half, while IFN γ production was unaffected. JNK knockdown did not impair CAR-T cell production but reduced the immunosuppressive cytokines IL-10 and IL-4 while maintaining IFN γ . These findings suggest that targeted control of JNK signaling may improve CAR-T cell interactions within the tumor microenvironment by controlling cytokine production, potentially leading to enhanced efficacy.

Abstract Name: Solar Cells from Germanane

The 2D germanium (Ge) analog to graphene is known as germanene. Hydrogenated-germanene, or germanane, was first synthesized in 2013 using relatively simple wet chemistry methods. Germanane has an inherently tunable direct band gap of approximately 1.6 eV, and high electron mobility, giving it great potential for application in photovoltaics, photodetectors, and thermoelectrics. As of 2023, some thirty-four different electronic device applications, including photodetectors, had been reported in the literature. However, a working photovoltaic device has yet to be realized. In support of efforts to achieve a working germanane photovoltaic, films of germanane, methyl germanane, and allyl germanane were produced. Fine layers of allyl germanane and methyl germanane were produced by spray-coating onto ITO-coated glass. To prepare the solutions, an assortment of solvents was tested with each compound to determine which solvent resulted in the best film. For methyl germanane, toluene produced the best film, and for allyl germanane, tetrahydrofuran (THF) worked best. The films were characterized to determine their optical and electrical properties. Once the optimal technique had been discovered for producing high-quality films of allyl germanane and methyl germanane, photovoltaic device structures were fabricated. These consisted of glass,

ITO, PEDOT-PSS, methyl germanane, allyl germanane, and silver. The devices were characterized using a Keithly Source-Meter to produce Current-Voltage (IV) curves. To date, devices have demonstrated diode behavior but not a photoresponse. Additional optimization is ongoing.

Abstract Name: Government Shutdowns and Holiday Flights Home: Utilizing Hierarchical Clustering Methods to Precondition Data for Linear Optimization

November 12th, 2025, marked the end of the longest government shutdown in U.S. history, lasting 43 days and costing 11 billion dollars. During periods of strain due to funding constraints, limited personnel, and delays, typical optimization algorithms used by airlines can become unstable and inefficient due to an increased number of variables and larger, more complex flight information. The focus of this paper is on improving the quality and organization of airport operation input data clusters produced by widely used agglomerative hierarchical clustering methods. In doing so, we can model complex nonlinear systems, such as those found in major disruption scenarios, with linearizations of the system that use these clusters to maintain speed, stability, and accuracy. Previous research has shown that clustering airline data before routing and scheduling computations is not only more efficient but also helps indicate which optimization methods should be used to evaluate it. However, only a few publications address how these samples are affected by major disruption scenarios and how algorithmic input must be adjusted accordingly. Using data from the Federal Aviation Administration and the Bureau of Transportation, we can assign a larger array of variables than previous studies, and then simplify and categorize the data using the aforementioned clustering methods. Once this data is preconditioned, an industry-standard constrained optimization solver will be used to solve the linearization of the system. Although clustering and processing the airline data before input reduces the fine details of the solution, forcing the data to conform to a linear system should produce gains in the stability and speed of the optimization solver, as well as maintain the overarching patterns needed to create schedules and minimize delays.

Abstract Name: Becoming Human: Barbie and the Fulfillment of Margaret Fuller's Feminist Vision

This paper explores Greta Gerwig's *Barbie* (2023) as a modern enactment of Margaret Fuller's feminist philosophy in *The Great Lawsuit* (1845). Fuller argued that women's liberation requires both inward and outward freedom, grounded in intellectual autonomy, spiritual agency, and self-reliance. *Barbie* reimagines these ideals through its central figure, tracing Barbie's journey from the superficial perfection of Barbie Land to her choice to "become human" and embrace imperfection and meaning. This transformation dramatizes Fuller's insistence that freedom is not a concession from society but an inherent right. Through close readings of Fuller's text alongside pivotal moments in the film, such as Gloria's monologue, Barbie's existential awakening, and her final declaration of personhood, this paper argues that *Barbie* transcends surface-level notions of equality to recover the deeper philosophical and existential dimensions of feminism. By placing

Fuller in dialogue with Gerwig's film, the study shows how Barbie revitalizes Fuller's radical vision for the twenty-first century, reaffirming that women's humanity lies in the right to live, think, and create freely.

Abstract Name: Predictors of Nonsuicidal Self-Injury in Transgender Youth: A Systematic Review

The aim of this literature review is to identify predictors of nonsuicidal self-injury (NSSI) engagement in transgender adolescents. Transgender individuals are at increased risk of NSSI engagement, and adolescents at the greatest risk of engaging in NSSI out of any other age group, as consistently established in the existing literature. Transgender people are at heightened risk of experiencing distal risk factors discussed in Nock's theoretical model of NSSI as per the minority stress model and are therefore more likely to engage in NSSI. A systematic review of articles published in the past ten years in the American Psychological Association's PsycInfo database identifying predictors of NSSI engagement among transgender adolescents was conducted. Existing literature has identified predictors for transgender adolescents engaging in NSSI which generally fall in three main categories: social context, mental health problems, and self-concept. Predictors which emerged most frequently in the literature include poor connectedness and support from family, poor perceptions of school safety, and societal stigmas against transgender people. In order to decrease NSSI risk in transgender adolescents, efforts towards decreasing stigma and increasing support in schools and society are necessary. Future research on predictive factors for NSSI engagement is necessary for clinicians to best serve gender diverse populations.

Abstract Name: Barriers To Promotion for Women in U.S. Corporate Business

Despite decades of progress in women's workforce participation, women in the United States continue to be significantly underrepresented in senior corporate leadership. This project examines the persistent barriers that limit women's promotion into executive roles. These structural obstacles restrict women's advancement and contribute to situations where women are promoted into precarious leadership positions with a higher likelihood of failure. Understanding how and why these patterns persist is essential for developing strategies that promote equitable leadership pipelines and organizational cultures. Existing scholarship highlights two dominant themes. First, that women face invisible institutional and cultural barriers that prevent upward mobility, otherwise known as 'the glass ceiling effect.' Second, that when women do reach leadership roles, they are disproportionately placed in unstable or high-risk situations, otherwise known as 'the glass cliff effect.' While this body of research has provided strong quantitative evidence of performance disparities and promotion patterns, it has offered limited insight into the lived experiences of women who have navigated these executive environments. Prior studies rely heavily on numerical data, leaving a gap in qualitative accounts directly from former or current women executives. This study addresses that gap by asking: What contributes to the lack of women promoted into executive roles in U.S. corporate business? The project employs a mixed-methods design. Quantitative data will be obtained in the form of updated national statistics

on women's leadership representation, promotion rates, and organizational outcomes. Qualitative data will be collected through interviews with women CEOs and executives, focusing on their experiences with structural barriers, leadership opportunities, organizational support, and moments of risk or instability. By integrating these data sources, the study seeks to identify recurring patterns and factors that shape women's access to executive advancement, offering a more comprehensive understanding of the mechanisms that uphold the glass ceiling and create glass-cliff conditions.

Abstract Name: Mechanistic Investigations into Aldehyde Deformylation Reactivity of Bioinspired Heme Peroxo Intermediates: Critical Insight into C–C bond Cleavage Mediated by Cytochrome P450 Aromatase

Heme enzymes play a critical role in activating dioxygen for oxidative chemistry in biological processes. This activation could occur via the binding of dioxygen to a ferrous heme active site, followed by one-electron reduction and proton-assisted heterolytic cleavage of the O–O bond. Therein, mid-valent heme peroxo (heme-PO) species have emerged as a key active intermediate. Human aromatase is one such heme enzyme that catalyzes the conversion of androgens to estrogens in steroidogenesis. The third step of aromatase involves the loss of the C19 aldehyde group as formate, and a concomitant aromatization of steroid ring A. This unique oxidative C–C bond cleavage reaction is proposed to involve a heme-PO species as the active oxidant, albeit minimal experimental evidence has been presented. Aromatase inhibitors (AIs) are at the forefront of clinically validated therapeutics for postmenopausal breast cancer. Gaining mechanistic insights into aromatase function is therefore essential and urgent for the design of next-generation AIs with improved efficacy and reduced side effects. Bioinorganic model chemistry provides a powerful toolkit towards this effort, uniquely enabling the synthesis of highly effective bioinspired mimics and the characterization of relevant reactive species using a medley of spectroscopic and theoretical methods. To probe the deformylation reactivity landscape of heme-PO adduct, we employed bioinspired heme-peroxide mimics with electronically disparate iron centers in conjunction with structurally varied aldehyde substrates. Detailed kinetic analyses reveal the electrophilicity of the substrate and the nucleophilicity of the peroxo moiety being critical determinants of the deformylation rates. Coupled with thermodynamic, radical trapping, isotope labeling studies, and complementary computational investigations, we demonstrate the likelihood of an initial enolization followed by a nucleophilic attack mediated by heme-PO on aldehyde substrates, which is overall rate-limiting. The characterization of a key heme peroxyhemiacetal reaction intermediate is also presented.

Abstract Name: Establishment of Peri-Implant Disease Models in Lewis Rats

Peri-implant disease (PI) is an inflammatory condition involving soft and hard tissues surrounding dental implants and represents a major contributor to implant failure, affecting 15% - 56% of all dental implants. The progression from peri-implant mucositis to peri-implantitis involves a shift from reversible soft tissue inflammation to irreversible bone destruction and loss of osseointegration. As the number of dental implant procedures continues to increase, there is a growing need for reliable experimental models to study their progression and treatment. Despite the clinical significance of peri-implantitis, there is currently no standardized small animal model that replicates its biological and structural features. This study focuses on developing peri-implant disease models in Lewis rats to study disease progression and quantify disease-associated bone loss using high-resolution microCT imaging. In an ongoing study, a total of 23 twelve-week-old Lewis rats are divided into three groups: control (n=3), peri-implant mucositis (PIM, n=10), and peri-implantitis (PI, n=10). All rats will receive commercially pure titanium screws in the maxillae and undergo a 28-day healing period to allow osseointegration. After the healing period, a 6-0 silk ligature will be introduced in select rats to induce inflammation. Rats harvested at 7 day post ligature will model peri-implant mucositis, while those harvested at 14 days post ligature will represent peri-implantitis. Implant-only control animals will undergo surgical re-entry without ligature placement to confirm that bone loss results specifically from inflammation. Harvested maxillae will be analyzed using microCT to assess peri-implant morphology, quantify bone volume fraction (BV/TV), and measure the vertical distance from the implant head to alveolar bone crest. Statistical analyses at a 0.05 significance level will compare bone loss among groups. We hypothesize that ligature placement will significantly reduce BV/TV and increase vertical bone loss relative to controls, validating the induction of peri-implant disease.

Abstract Name: Beyond Mobility: The Role of Prosthetic Innovation in Emotional Healing and Identity Reconstruction

The field of rehabilitation engineering extends beyond restoring physical movement; it also plays a vital role in rebuilding confidence, identity, and social connection for amputees. Despite major advances in prosthetic technology, many users continue to face psychological and emotional challenges that affect their overall quality of life. This paper investigates how the design and functionality of prosthetic devices influence the mental health and emotional recovery of amputees. Drawing on interdisciplinary research in engineering, neuroscience, and psychology, this study examines how sensory feedback, neural communication, comfort, and aesthetic personalization contribute to users' mental well-being. Key themes include the role of sensory restoration in emotional healing, empathetic design for comfort, neural reconnection for embodiment, aesthetic appeal for social acceptance, and technological integration for holistic rehabilitation. Findings from existing studies indicate that sensory feedback can reduce phantom limb pain and enhance user enjoyment, that socket design directly influences comfort and satisfaction, and that user participation in aesthetic customization increases motivation and confidence. Neural stimulation helps reestablish communication between the brain and the prosthesis, while the combination of psychological and technological approaches promotes independence and emotional resilience. These results demonstrate that prosthetic devices shape mental health as significantly as they restore physical function. Therefore, successful prosthetic designs must integrate emotional well-being, personalization, and functional performance. By aligning mechanical precision with psychological understanding, rehabilitation engineering can create prosthetics that not only restore mobility but also help amputees reclaim their sense of self, confidence, and belonging.

Abstract Name: Real-Time YOLOv8-Based Object Detection and Reporting for Construction Sites

This paper presents a real-time computer vision pipeline for automated monitoring and reporting construction sites. The system contains a custom trained YOLOv8 object detector with optical character recognition (OCR) to generate daily site reports with no human intervention. The YOLOv8 model was trained on a curated dataset, which had been annotated via CVAT, to recognize critical construction objects: steel reinforcement, person, construction workers, concrete buckets, and achieving a mean average precision (mAP) of over 95%. An OCR module parses delivery note using a Python script that extracts tabular data into CSV format. An automation script then compiles detection results and delivery records into a structured HTML/PDF report. The proposed framework demonstrates end-to-end automation: from video frames and documents from the construction site to a finalized daily report. This paper details the training process, system architecture, and field results that emphasize that real-time object detection with document parsing can significantly streamline construction progress tracking and safety management.

Abstract Name: Developing and Calibrating a Multi-Factor Scour Prediction Equation: Insights from the Schoharie Creek Bridge Collapse

Bridge scour is the leading cause of hydraulic structural failure. To manage this risk, the civil engineering community relies on standard empirical models, most notably the HEC-18 CSU equation, which provides a conservative safety envelope for design. While these equations are excellent for predicting maximum scour in cohesionless sand, challenges naturally arise when applying them to complex field settings where the geology resists erosion differently than laboratory sand. This study presents a forensic hydraulic analysis of the 1987 Schoharie Creek Bridge (I-90) collapse in New York. Leveraging forensic data from the NTSB and USGS, this ongoing research reconstructs the hydraulic conditions of the record 1987 flood. This study focused on the scour depth at Pier 3, which was identified as the primary cause of the bridge's collapse during the heavy rainfall. First, the hydraulic state at Pier 3, which had collapsed during the flood peak was modeled using Manning's equation and historically observed discharge data to determine specific parameters, including the approach velocity, and Froude number. It is hypothesized that the standard CSU equation, designed for safety, predicted a theoretical scour depth significantly greater than the actual 3-meter hole documented by forensic divers, due to the resistive properties of the riverbed's dense glacial till. To solve this, the primary objective is to develop a site-specific geomorphic calibration factor. By analyzing the discrepancy between the theoretical prediction and the forensic evidence, this study aims to derive a correction coefficient based on the bed material's critical velocity. The expected outcome is a calibrated predictive model that determines if the collapse was a hydraulically inevitable consequence of the design, regardless of the geological resistance. The contribution of this study lies in providing a refined, location-specific scour assessment approach that bridges the gap between generalized equations and real forensic evidence.

Abstract Name: Bile Acid Salt Metabolites Inhibit Pro-Inflammatory Th1 and Th17 Cell Polarization

The intestinal immune system operates at the complex intersection of microbial metabolites and host regulatory networks, yet the influence of bile salts on adaptive immunity remains unclear. Recent findings have hinted at their potential to regulate immune cell differentiation. In this study, we investigated the capacity of bile acid metabolites on Th1 and Th17 cell polarization and its implications in the pathogenesis of colitis and inflammation-related colon cancer. C57BL/6 WT mice were maintained and euthanized in accordance with IACUC guidelines. Spleens were harvested and CD4⁺ naive T cells were isolated. T cells were cultured in DMEM, and conditioned media where Th1 was supplemented with IL12 and Anti-IL4, and Th17 was supplemented with IL6, TGF β , Anti-IFN γ , and Anti-IL4. Cells were stimulated with PMA/ionomycin/GolgiStop and stained for IFN γ and IL-17A, and data was analyzed using Attune FlowCytometry. For Th1 polarization, treatment with 20 μ M IsoAlloLCA led to a decrease in Th1 polarized cells compared to DMSO control (16.11% vs. 69.25%), while Deoxycholic acid (DCA), 3-oxo-deoxycholic acid (3-oxo), and lithocholic acid (LCA) showcased levels of 60.5%, 53.34%, 62%, respectively. For Th17 polarization, IsoAlloLCA reduced Th17 cells to 7.57% compared to 46.73% in DMSO controls. DCA, 3-oxo, and LCA also suppressed Th17 polarization to 34.07%, 18.55%, and 29.16%. Th1 polarization was partially inhibited by secondary bile acids, particularly DCA and 3-oxo. Th17 polarization was completely inhibited by primary and secondary bile acids. These findings point to a potential link between bile acid metabolism and suppression of inflammatory T cell responses.

Abstract Name: The Analysis of Sensor Based Geo-Spatial Data to Determine the Effect of Environmental Factors on Stress and Walkability

Neighborhood walkability is a significant factor for allowing older adults to maintain regular physical activity, which is linked to their overall physical and mental health. Previous studies have shown that these effects are worsened in low-income communities, finding decreased walkability in a low-income Latino community by analyzing data collected during two-week walking trip samples using wearable and mobile devices. The dataset includes both geo-spatial and physiological data, including heart rate, electrodermal activity, and body acceleration. Participants also completed surveys after each walking trip and reported environmental stressors encountered during their walk. This project aims to further analyze this data to explore associations between stress and other walkability-related factors through cross referencing self-

reported stressor data with location and physiological signals. Environmental stressors reported by participants were categorized into various categories (e.g., traffic, people, weather, etc.), allowing for analysis of different types of stressors commonly encountered by pedestrians during trips. Heatmaps were also created to find locations with the highest density of stress reports for each category. Identifying areas where different types of stressors were most commonly reported allows signal data to be examined in specific analysis windows, providing insight into the effect that each type of stressor has on participant physiology. Additionally, ambient environmental factors such as temperature and humidity were also considered during analysis to determine the influence of these factors during trips. The expected results of this study are to identify the most important environmental factors that influence pedestrian stress and find potential improvements for pedestrian infrastructure. Additionally, this research builds upon the development of analyzing data collected from devices using computational methods.

Abstract Name: On Researching and Writing Celtic Folklore and Selkies

In my project I have aimed to complete research for the development of a graphic novel that revolves around the Celtic folklore creature “selkies”, seal-like people who don seal fur coats and transform into seals themselves. I want to be able to share information about these creatures from folklore while also drawing inspiration from the folklore itself so that I can teach others about the creatures I myself am so passionate about. My goal was to develop the plot for a graphic novel revolving around these creatures while also displaying queer themes such as transgender identities. I also aimed to gain experience in depth research for fiction. I’ve researched various sources, from research papers and interviews to primary sources including documented folklore and song. I’ve discovered that there are a wide variety of resources to pull inspiration from, and that there are a variety of ways to pull inspiration from these sources. Ultimately, I aim to have created a finished plot for the planned graphic novel, as well as a reflection on my experience as a writer in doing research. I hope to present my outcomes on both my writing and what I managed to accomplish through the fellowship as well as how I can carry the experience I’ve gained into the future as a writer and an artist.

Abstract Name: Automated Machine Learning Analysis of Axonal Swellings in an Alzheimer’s Disease Model

Automated detection and classification of pathological features in neurodegenerative diseases, such as Alzheimer’s disease (AD), is crucial for understanding disease progression and developing therapeutic interventions. Axonal swelling, an early pathological marker in AD, is traditionally quantified manually, which is time-consuming and prone to variability. To address these challenges, we developed ASCAM

(Axonal Swelling Classification and Analysis Model), a two-part machine learning solution. ASCAM first uses a classification model to distinguish images containing axonal swellings from those without, followed by an object detection model that accurately identifies and quantifies swellings in stained pons brain sections from AD mouse models. The object detection model was trained on 7,144 images and tested on 188, with ground truth annotations provided by a blind observer. Data augmentation techniques, such as rotation and scaling, were employed to enhance generalization. Using a deep learning architecture optimized for small object detection, the model achieved a boundary F-score of 0.6636 at a 4-pixel threshold and a Pearson's correlation of 0.961 with manual quantification. The classification model, which differentiates swelling-positive from swelling-negative images, achieved a validation accuracy of 93%, streamlining the analysis pipeline. Together, these models provide a scalable solution that significantly reduces the time and variability associated with manual methods, offering a robust tool for neurodegenerative disease research. This method can also be adapted for detecting other pathological features across various staining techniques, with potential applications in neurodegenerative, cancer, and inflammatory disease research.

Abstract Name: Exploring DLL3 CAR-T Cell Therapy and Antibody Drug Conjugate Payloads in Small Cell Lung Cancer

Background: Small cell lung cancer (SCLC) is a very aggressive malignancy for which there are limited targeted therapies and low long-term survival; however, the approval of tarlatamab, a bispecific T-cell engager, has shifted therapeutic options towards surface targeting therapies. Most molecular subtypes of SCLC express DLL3, a Notch ligand, an attractive surface target of T-cell redirection therapies like chimeric antigen receptor T-cells (CAR-T). Nevertheless, the efficacy of CAR-T cells in more complex 3D models is yet to be explored. Although antibody-drug conjugates (ADCs) based on topoisomerase I (TOP1) payloads such as SN-38 and deruxtecan have demonstrated efficacy, these responses are limited. Methods: SCLC spheroids were derived from SCLC cell lines and treated with DiO-labeled, DLL3-targeted CAR-T cells, CD56-targeted CAR-T cells, non-targeted T cells or chemotherapy. Spheroid growth was tracked by brightfield and fluorescent imaging. To test the cell viability using a panel of SCLC cell lines against microtubule inhibitor ADC payloads and the CDK2 inhibitor, proliferation assays were carried out. Results: DLL3 CAR-T cells demonstrated significant cytotoxic effects on 3D spheroid growth over 15 days, as compared to spheroids exposed to non-targeted T cells. Conversely, spheroids with lower DLL3 expression the CD56 targeting CAR-T cells were more effective. SCLC cell lines showed high sensitivity to microtubule inhibitor ADC payloads, including mertansine and MMAE, at 10 μ M. Conclusion: Our results indicate that SCLC spheroids can be used for testing DLL3-targeting CAR-T cells, especially in neuroendocrine subtypes with high surface expression. Future experiments will test the reliance of CAR-T cells on target expression (using siRNA) and test the CAR-T cells in combination with other agents. Additionally, the sensitivity of SCLC cell lines to microtubule inhibitor-based payloads implies that ADCs using these payloads may be viable options when resistance to ADCs with TOP1 inhibitor payloads occurs.

Abstract Name: Exploration of Convolutional LSTM Models Architectures on Stock Market Forecasting

There have been many attempts to capture detailed trends from the inherently volatile nature of financial forecasting such as the S&P 500 Index, with the use of Long Short-Term Memory (LSTM) networks for these predictions. These models, which are types of Recurrent Neural Networks (RNNs), excel in capturing long-term dependencies, such as financial stock predictions, thereby enabling the capture of trends as well. However, due to the volatile and noisy nature of the market, these models fall short of capturing key details in both the long and short term. Recent literature has described the use of a hybrid model, the Convolutional Neural Network CNN-LSTM, combining both neural networks. This combination allows the CNN to focus on short-term patterns, extracting rich features from the input data sequences, while the LSTM focuses on the long-term trends in the market. This study aims to test various architectures of the CNN-LSTM, including sequential, where CNN output feeds directly into the LSTM, and parallel, where CNN and LSTM process the input data independently and their outputs are combined models, to understand how the CNN contributes to richer features for predictions and pattern extraction on our main target of the closing price of S&P 500 index. Across the time periods of 2019, 2020, and 2025, the parallel CNN-LSTM model was able to outperform both the baseline LSTM and the sequential CNN-LSTM models, achieving better predictive accuracy. This success varied depending on the time period, with the best results occurring during 2019, achieving an MAE (Mean Absolute Error) of .87 compared to the best result of an MAE of 5.04 for the base LSTM. This study employs an ablation study, where multiple model architectures with the same hyperparameters are compared to explore the results across the chosen time periods.

Abstract Name: From Wave-functions to Tangible Models: Redefining Electron Cloud Representations Based on a Multimodal Approach

This research project builds a quantitative model for visualizing electron probability distribution by describing a median-based multiple “cloud bands” for each orbital. Traditional methods propose one distance for the atomic radii calculated from the wavefunction of the effective active electrons. Starting with the simple models that take the mean or the peak radial distance using Hydrogen-like wavefunctions, Theoretical calculations using Self-consistent field SCF function, Density Function Theory (DFT), Transverse Energy Equation, empirical studies of J.C. Slater, and various methods to calculate Van der Waals radius often lead to different results for a single location. In this research, we propose a multimodal analysis of electron clouds using each mode as a separate band. The number of modes are given by $m=n-l$ based on the principle and the angular momentum Quantum numbers of the active electron. Based on the zeroes of the radial wavefunctions, we treat 4s orbit as 4 separate modes and 3p orbit as 2 separate modes for the electron cloud, etc. Using Desmos-generated integral curves of the radial probability function, we identify the median radius r_m , as the point where the cumulative probability reaches 50%. We further our studies to analyze the standard deviation and the probability of each mode. Using this methodology, we were able to obtain the inner and outer radii of different electron shells and then scale these values up to create larger 3-D tangible models that keep the same proportions as the most probable regions for the electron clouds instead of a single location.

Abstract Name: Exploring CNT/PEDOT Coated Electrodes for THC Detection

The increase in legalization and recreational use of marijuana products is leading to a growing number of drivers operating motor vehicles under its influence. Currently, there is no roadside test available for law enforcement similar to a breathalyzer currently used for alcohol. Electrochemical detection is attractive for many reasons such as high sensitivity, fast response, and simplicity with making a portable device that can be used with little technical background. Selectivity is especially important, as law enforcement must be able to distinguish between psychoactive compounds like D9-tetrahydrocannabinol (THC) and non-intoxicating medicinal compounds such as cannabidiol (CBD). Previous work with glassy carbon electrodes shows that both THC and CBD can be electrochemically oxidized at similar potentials. This means that it is not selective towards THC. The long-term goal of this project is to develop a selective sensor for roadside detection for THC. The research presented here will focus on modifying glassy carbon electrodes with 3,4-ethylenedioxythiophene polymerized (PEDOT) with polystyrene sulfonate (PSS) and carbon nanotubes (CNTs) to serve as an electrocatalyst toward the selective detection of THC. The direct electrochemical oxidation as well as the electrochemical reduction of the species created when THC is oxidized using hypervalent iodine reagents will be explored as possible detection schemes. Considering the phenol groups on the THC are the electroactive component, initial studies presented will include model phenolic compounds. The CNT/PEDOT layer will be analyzed through scanning electron microscopy imaging and probed using cyclic voltammetry.

Abstract Name: IFET-1 Controls Nucleocytoplasmic Shuttling of IFE-3 in *C. elegans* Germ Cells

Cellular ribonucleoprotein (RNP) complexes play an important role in the post-transcriptional regulation of gene expression throughout development. Under intrinsic and extrinsic stress conditions, cells form RNP condensates that bind mRNA and coordinate functional gene expression, i.e. protein synthesis. One key factor of RNP complexes is the RNA-binding protein eIF4E, which binds the 5'-methylguanosine (m7G) cap of mRNAs and typically promotes recruitment to ribosomes. Misregulation of this pathway has been implicated in diseases such as Alzheimer's, ALS, and cancer, making it a key focus of current research. In *C. elegans*, a major germline expressed eIF4E ortholog, IFE-3, plays a crucial role in oocyte cell fate and embryonic viability. IFE-3 binds m7G caps and, along with its cognate transporter protein IFET-1, regulates a unique subset of mRNAs. Studies have shown that under stress conditions, IFE-3 localizes to perinuclear and cytoplasmic RNPs to regulate the translation of mRNAs. Here, we utilize CRISPR/Cas9 fluorescently-tagged RNP factors to investigate the localization of IFE-3 in response to various stressors. While previous work has shown that IFE-3 localizes to cytoplasmic RNPs called stress granules under heat shock conditions, we demonstrate that depletion of IFET-1 abrogates this localization. Instead, IFE-3 accumulates in the nucleus of

both early germ cells and oocytes when IFET-1 is depleted. Interestingly, this nuclear localization was observed for IFE-3 but not for its close paralog IFE-1, possibly suggesting a previously unrecognized role for IFET-1 in nucleocytoplasmic shuttling of IFE-3 in germ cells.

Abstract Name: Trial By Media: The Verdict Gap Between Public Opinion and the Courts

This research project investigates the phenomenon of “trial by media,” in which extensive news and social media coverage of high-profile criminal cases shapes public opinion and produces a “public verdict” that may diverge from the jury’s final decision. Understanding this dynamic is essential to evaluating how media environments influence the legitimacy and perceived fairness of the judicial system, particularly in an era where social media accelerates the spread of narratives and public judgments. Guided by theories of media framing, agenda-setting, the spiral of silence, and judicial legitimacy, this study examines how media narratives and biases construct perceptions of guilt or innocence long before a verdict is reached. Using a mixed-methods comparative design, this project analyzes six major cases: three from the pre-social media era (O.J. Simpson, the Menendez brothers, and the Central Park Five) and three from the social media era (R. Kelly, Depp–Heard, and Alex Murdaugh). Data will be collected from traditional news sources across the political spectrum, archived public opinion surveys, court records, post-trial juror interviews, and social media metrics. The study hypothesizes that cases occurring during the social media era will show a faster, more polarized formation of public verdicts due to the speed, virality, and algorithmic amplification of online content. It further predicts that increased partisan divergence in media framing will correlate with larger gaps between public opinion and jury verdicts, and that higher volumes of negative coverage will align with harsher public judgments. While social media is expected to exert a strong influence on public perception, the findings may reveal that juries remain more anchored to legal evidence than to dominant media narratives. Ultimately, the research aims to clarify the evolving relationship between media and the justice system and to offer recommendations for courts and journalists seeking to preserve the fairness and integrity of criminal trials.

Abstract Name: Retinal OCT Automated Layer Segmentation using Minimum Cost Path Algorithm

Optical Coherence Tomography (OCT) is a non-invasive eye imaging tool used to diagnose, monitor, and guide treatment planning. OCT B-scans are analyzed by identifying the retinal layers and measuring the thickness of each layer. Currently, many B-scans are segmented manually, which can take over 40 minutes

per image. As a fast, reliable automated method for retinal segmentation is lacking, we propose an automated segmentation approach using the Minimum Cost Path (MCP) algorithm to reduce processing time and accurately identify retinal layers and their thicknesses. OCT imaging (Ganymede, Thorlabs) was performed in New Zealand white rabbits at 4 months of age. The algorithm performed retinal layer detection in three stages: preprocessing, segmentation using MCP, and visualization. During preprocessing, Otsu thresholding identified the largest object, followed by standard blurring and contrast enhancement. In the segmentation stage, the Sobel operator was applied to calculate an intensity-gradient map, which measures the strength of local intensity changes in each pixel. The MCP algorithm then used this map to find the lowest-cost path corresponding to the strongest edges. This process is repeated until all edges are detected. The MCP algorithm showed significantly improved efficiency, reducing segmentation time to approximately 8 seconds per image while measuring the average thickness of multiple retinal layers. However, several layers were often misidentified. The GCL and choroid were oversegmented. On the other hand, the sclera and INL/ONL/OLM were frequently underdetected due to high noise levels, which prevented the algorithm from finding a stable path. Our results demonstrate the applicability of the MCP algorithm as an automated OCT segmentation system. Although the algorithm's reliability is limited by image quality, it shows potential as an assistive tool for ophthalmologists in diagnosis and monitoring.

Abstract Name: From Old English to Modernity: The Evolution of English From a Morphological Perspective

The presentation focuses on the evolution of morphological aspects of the English language from the Old English period to Middle English and then Modern English. Morphology refers to the form and structure of words and morphemes of a given language. This research is a small scope of a broader, research project detailing the evolution of English over time from its respective morphological, syntactical, and phonological aspects. Then analyzing it typologically to determine whether English retains aspects of Germanic languages from a typological scope, for instance, grammatical gender and case such as nominative, genitive, dative, accusative, and instrumental. This research scope discusses the evolution of inflectional morphemes, grammatically gendered language, and noun declension. Old English was a synthetic language, grammatically gendered, and case-marked for quantity and gender in nouns and verbs. Modern English, an analytical language, has no grammatical gender and no case markings for quantity or gender in nouns and verbs, Modern English also no longer inflects for its paradigms of case. English has morphologically simplified over time due to external influences such as Norman French and Old Norse. This presentation presents differences in English morphology over time, the paper concludes that, while English is genetically a Germanic language, after analyzing it typologically, I propose it does not retain aspects of a Germanic language due to its dissimilarities with its related languages.

Abstract Name: Design of an Integrated Silicone Mixing and Extrusion System for 3D-Printed Soft Robotic Applications

Soft robotics offers significant potential in healthcare and rehabilitation applications, yet traditional fabrication methods like silicone molding remain labor-intensive, slow, and geometrically constrained. This project presents a locally modified Fused Deposition Modeling (FDM) platform capable of directly printing silicone elastomer actuators with embedded pneumatic channels for soft robotic applications. The system integrates a custom dual-syringe extrusion pump by New Era (Model SyringeTWO) that precisely mixes and dispenses a two-part platinum-cure silicone (Dragon Skin™) in a 1:1 ratio immediately before deposition. By varying pump speed, the volumetric flow changes from 57.34 $\mu\text{L/hr}$ to 7515 mL/hr, enabling both fine-feature printing and rapid bulk infill within one setup. To address the long cure time of room-temperature silicones, a specialized end-effector with active thermal regulation was engineered. Ceramic cartridge heaters in machined aluminum heat blocks, combined with directed cooling fans, maintain a local process temperature between 40°C and 47°C around the nozzle, promoting rapid cross-linking upon deposition while minimizing premature curing inside the mixer and tubing. A microcontroller-based control loop monitors thermistor feedback and adjusts heater and fan outputs to preserve this narrow thermal window throughout the print. The printer was validated by fabricating functional artificial muscles with complex internal voids designed for pneumatic actuation. Printed structures proved airtight, flexible, and capable of repeated cyclic loading without catastrophic failure. Actuators with 40% infill reliably withstood internal pressures of 40–150 kPa over multiple inflation–deflation cycles without leakage, while individual print jobs were limited to 7–9 minutes by syringe pump stalling. This enabled consistent fabrication of airtight muscles with embedded channels suitable for pneumatic testing. Collectively, this integrated mixing, extrusion, and thermal-control system provides a scalable, rapid-prototyping route for silicone soft actuators, offering improved geometric freedom and reduced labor compared to conventional molding workflows. Further details will be presented during the conference.

Abstract Name: Black Sociological Data Visualization: Infographics Shedding Light on Black Oppression and Succession

This study examines the visual history of Black progress in the United States through the lens of early and modern infographic practices. While narratives of African American advancement are often preserved in texts, films, and essays, visual data has played an equally critical role in documenting both oppression and achievement. Beginning with diagrams of slave ships, labor maps, and other visual records of enslavement, this project traces how these forms established a foundation for later modes of graphic representation. The work of W.E.B. Du Bois, particularly the data visualizations created for the 1900 Paris Exposition, is analyzed as a pivotal moment in the evolution of modern infographics. Du Bois's charts not only advanced sociological inquiry but also offered a compelling visual testament to Black capability, resilience, and success in the post-slavery era. By connecting pre-emancipation diagrams to Du Bois's post-emancipation visualizations, this study argues that the origins of Black graphic design can be meaningfully situated within the broader and often overlooked history of visual documentation of slavery. Further, the project considers ongoing debates about the definition of infographics, expanding the category to include a range of historical visual media. Through a sociological and psychological lens, this research demonstrates how infographics shape cultural perception and contribute to the fight for justice and representation among Black communities.

Abstract Name: The COVID-19 Time Warp: Was that One or Five Years Ago?

Five years ago, in early 2020, the world was stunned by the virus that we later came to know as the coronavirus. The virus quickly spread, resulting in what we all know as the COVID-19 pandemic, which stole people's daily lives and later altered their experience of time. Many generational milestones were put on hold, such as benchmark birthdays, anniversaries, and high school and college graduations. Many teens and young adults lost crucial developmental stages and now suffer the consequences of spending every day indoors. This study examines how young and middle-aged adults perceive the passage of time during the early stages of the pandemic compared with post-pandemic reflections. The hypothesis suggests that individuals who experienced the pandemic at a younger age are more likely to report higher levels of time perception distortion, while older individuals are more likely to report lower levels of memory confusion related to the time period. Building on prior research by Ogden (2020, 2022) and Longro et al. (2025), this study uses a self-report online survey administered via Qualtrics to explore time distortion, mood, and task load across age groups. Preliminary results support the hypothesis, showing that older individuals perceive time as moving slowly, while younger adults report more ongoing time confusion in the years following. These findings shed light on the long-term psychological effects of the pandemic-related disruption and suggest age-related differences in how people rebuild and process emotions after trauma. The study's conclusions are consistent but limited by a small sample and reliance on self-report.

Abstract Name: Unraveling the Expression, Clinical Relevance, and Oncogenic Potential of DHX15 and Related DEAH-box RNA Helicases in Human Cancer

RNA helicases are motor proteins that utilize ATP hydrolysis to remodel RNA structures and RNA-protein complexes. A major subfamily, the DEAH-box helicases, is defined by a conserved Asp-Glu-Ala-His (DEAH) motif and includes critical members such as DHX8, DHX9, DHX15, and DHX16. DHX15, the functional homolog of the yeast spliceosomal disassembly factor Prp43, is essential for core RNA processing events, establishing it as a central node in post-transcriptional gene regulation. Dysregulation of RNA helicases is increasingly recognized as a driver in human malignancies. For instance, DHX15 is overexpressed in hematologic cancers, where it promotes resistance to apoptosis via NF- κ B signaling and correlates with poor patient prognosis. However, a comprehensive systems-level analysis of DEAH-box helicases in solid tumors remains limited, particularly across epithelial cancers. In this study, we employed an unbiased systems-level approach to assess the expression, clinical significance, and functional roles of over ten DEAH-box helicases. This was accomplished using both cancer cell lines and comprehensive clinical datasets, including The Cancer Genome Atlas (TCGA) and the Clinical Proteomic Tumor Analysis Consortium (CPTAC). We found that several DEAH-box helicases, notably DHX15, were significantly overexpressed at both mRNA and protein levels across multiple tumor types compared to non-malignant

controls. Furthermore, expression of several DEAH helicases correlated significantly with adverse clinical parameters, including high tumor grade, advanced stage, and poor patient prognosis. Using genome-wide functional genomics screens, we explored both upstream regulatory mechanisms and downstream effectors to elucidate the roles of these helicases in cancer progression. Altogether, our findings provide a critical foundation for understanding DEAH-box RNA helicases as key contributors to tumor biology and highlight their potential as therapeutic targets in human cancer.

Abstract Name: An Algorithm to Determine Trail Profile Based Upon Distance Sensor Arrays and IMU Inputs

Advanced development techniques for mountain bike systems are becoming increasingly prevalent as both recreational and professional athlete interest in mountain biking has grown. There are methods for testing and simulation where the response of a bicycle is tested for the terrain and profile of a specific trail. However, information regarding the measurement and modeling of such surface profiles is severely limited. The present work is an investigation of an instrumentation configuration which will allow the measurement of trail profiles. The system consists of an array of laser-based distance sensors which are mounted to the hubs of the front and the back wheel of the bike. However, previous work indicated that data from the distance sensors alone is insufficient to determine an accurate trail profile. As a result, the current work involves the inclusion of a 9-axis IMU to supplement the algorithm which determines the trail profile based upon measured data. Utilizing measured values from the distance sensor arrays and IMUs, a geometry-based algorithm has been developed to determine the trail profile for a number of "obstacle scenarios." The algorithm starts by cycling through an expansive case structure to determine the obstacle scenario, then uses the results of the case structure to determine which geometric relationships will return the correct height of the front wheel hub at a given instant. This work is being carried out in parallel with mechanical and electrical implementation. Once the measurement system is operational, experimental data from controlled scenarios will be used to validate the performance of the algorithm

Abstract Name: Wanted: Dead and Immunogenic. Combining Metformin and Chemotherapy to Promote Immunogenic Cell Death in Triple-Negative Breast Cancer

Cancer has a troublesome ability to evade immune detection. Cancer cells often avoid expressing imperative antigens, allowing them to stay undiscovered and promote tumor persistence or recurrence after treatment. Investigating ways to not only induce death, but to also reduce tumor recurrence is crucial in triple negative

breast cancer (TNBC) research, as patients with this subtype are up to 2.6 times more likely to experience recurrence compared to patients with other breast cancers. One way to prevent tumor recurrence is by engaging the immune system, enabling it to recognize and exterminate cancer cells that could cause recurrence. This independent research will continue into the spring semester, establishing whether a common pharmaceutical substance, metformin, in combination with the platinum-based chemotherapies cisplatin and oxaliplatin will induce immunogenic cell death (ICD) in TNBC cells. Ultimately, this combination treatment will augment antitumor immune responses that have been observed in our previous in-vivo study with chemotherapy treatment alone. This project will test the hypothesis that metformin can pharmacologically trigger autophagy in TNBC cells and that, when combined with platinum-based chemotherapy, this process promotes ICD. In-vitro experiments using the murine E0771 cell line reveal that metformin treatment significantly increases ATG5 protein levels compared to the vehicle control dose, successfully indicating that metformin treatment triggers autophagy. I will conduct further in-vitro experiments with the combination treatment to analyze calreticulin exposure on the cell membrane and ATP release to identify markers of ICD.

Abstract Name: To Eat or Not to Eat: Anxiety, Depression, and Eating Behavior

The purpose of this research study is to better understand the relationship between eating behaviors and mental health outcomes among college students. According to Martin (2024), among college students, poor eating habits and limited consumption of vitamin-rich foods are prevalent; meanwhile, high-fat meals and high-calorie foods are frequently consumed. Busy schedules and financial limitations make college students choose the easy meal. Among college students, depression is a common mental health disorder. College students deal with a lot of stress through their studies, which is an important risk factor for mental health disorders, like depression and anxiety (Liu, et al., 2020, p. 1). This quantitative research study utilizes established, validated, and reliable measures to study the target variables. Seated college student perspectives are gathered using the Patient Health Questionnaire-9 (PHQ-9), Three-Factor Eating Questionnaire, and the Generalized Anxiety Disorder-7 (GAD-7) assessments. Participants are recruited via email and complete the instruments through a secure online platform, with approximately 100 participants expected. Data collection is ongoing and will be completed by late February. Analysis will include descriptive and correlational statistics, and post-hoc analysis as appropriate. Results are expected to align with established literature and provide evidence that eating behaviors and mental health outcomes are significantly related. Furthermore, it is expected that these relationships will be stronger in female participants and those recently enrolled in college. Understanding the relationship between food and mental health has long been a focus of psychological research. Literature has established multifaceted consequences for poor eating behaviors and mental health, with impacts on institutional concerns like student retention and success, and student concerns, like emotional well-being and physical health. This study will provide insight and recommendations that can help address these issues at both the individual and institutional levels.

Abstract Name: A Low-Cost Workflow for Culturing and Teaching with *Halobacterium Salinarum*

Halobacterium salinarum is an extremophilic archaeon that thrives in high-salt environments and develops a striking reddish pigmentation, making it an attractive model organism for teaching and research. This project focused on creating a simple, low-cost liquid culture medium to maintain *Halobacterium* for use in undergraduate biology laboratories and as part of the Padron campus culture collection. Cultures of *H. salinarum* were grown at 37°C in media with salinities ranging from 25% to 30%. Growth was monitored by absorbance readings and visual inspection of the characteristic orange pigment. Microscopy was also used to assess cultures. To prepare smears, cells were briefly immersed in 3% acetic acid, which removed excess salt crystals and fixed the cells for differential staining. This adjustment allowed clear observation of the pleomorphic, rod-dominant morphology without interference from salt. When broth cultures reached A660 readings of 1.0–1.2, no more than 50 mL was needed to obtain a high yield of crude DNA for extraction. Using the InstaGene protocol with volumes of 1–2 mL at high absorbance density produced DNA with good purity based on A260/280 ratios. This micro-extraction provides material suitable for basic molecular biology exercises. Together, these results demonstrate an accessible and reproducible workflow for culturing, observing, and extracting DNA from *Halobacterium salinarum*. By keeping materials inexpensive and procedures straightforward, this project supports sustainable use of extremophiles in undergraduate biology and microbiology laboratories and expands hands-on research opportunities for students.

Abstract Name: The Textual, Cultural, and Commercial Publishing Intersections of Young Adult (YA) Fiction

My research uses genre theory as a primary frame to examine and explain the virality of Young Adult (YA) fiction. One of the most vibrant, rapidly growing divisions of the publishing industry is the YA market. Yet, the current demand for and critical approach to YA are messy in terms of artistic genre, readership, and the identity being defined. From the 1970s to the mid-1990s, writers (and the publishing industry) reimagined how to speak directly to the interests of a new adolescent audience. Global hits such as *Harry Potter* (1997-2007) by J.K. Rowling and *The Hunger Games* (2008-2025) by Suzanne Collins have an impressive multigenerational appeal. YA's audience is deceptively broad, and many fans are not within the traditional target age group. More than half of its book buyers are over 18, and among them, the majority are women aged 30 to 44. The intersections between this multifaceted audience, conventions and craft, and industry trends have been described but not broadly theorized. The core developmental change during the teenage years is becoming an independent person, and YA is often the first genre readers choose outside of school or parental influence. In this way, the first genre you acculturated to is now incessantly tied to your greater experiences as a reader and upholds the nostalgic need to return to this first "outside identity" in future texts. This study moves the conversation beyond the assumptive criticism of YA's scholarly appropriateness. Historically, adult literary fiction often presumed a universal (and often adult, male, white) perspective. The boom of YA is a clever response to a cultural hunger for stories that treat interiority—especially of young and marginalized voices—with a seriousness that parallels how it is actually lived. Consequently, Young Adult fiction best explains how genre is co-opted and sustained outside its writers.

Abstract Name: Organized Existential Resistance: Philosophy, Force and Art

Organized Existential Resistance (O.E.R.) is the technique of resisting oppressive forces with the use of existentialism. Existential resistance first emerged from French philosophers, psychologists, freedom fighters, and artists who fought against fascist occupation during WWII. Both the Existential Side and the Resistance Side of O.E.R have multiple components that are covered in this research. First are the six major themes of existentialism that arose as acts of resistance. Existential themes include Radical Freedom and Responsibility; Meaning Making amid Suffering; Solidarity and Intersubjectivity; Revolt and Revolutionary Consciousness; Courage, Anxiety, and Moral Risk; and Creative Expression as Liberation. Further elaboration of the Meaning Making amid Suffering theme is provided. Also included are the stories of freedom fighters, which show different methods that were used to resist fascism. A brief history of John Heartfield, and examples of his work, are told to explain Creative Expression as Liberation. As well as the story of Lucie and Raymond Aubrac, who risked their lives to resist Nazi occupiers. When Raymond was captured, Lucie organized a group effort to retrieve Raymond from a Nazi Gulag. Their friend and colleague, Jean Moulin who was also captured with Raymond, showed steadfast determination by not divulging information despite being tortured to death. Lastly this research provides information on how the knowledge of Organized Existential Resistance (O.E.R.) can be applied to the current day.

Abstract Name: Precrastination in the Team Setting

Precrastination is the tendency to begin and/or complete tasks as soon as possible—even at the expense of additional effort—to relieve the mental burden of having unfinished work. An individual is considered a precrastinator when they consistently exhibit this rushing behavior when a task is given. Recently, researchers have begun to examine its implications for individuals who engage in it. However, there is limited research examining how this phenomenon specifically affects team dynamics. The impact of precrastination on team dynamics should be better understood in the team context because rushing behaviors can influence the behaviors of others, potentially leading to varying team experiences and outcomes. Thus, the present study explores how precrastination impacts dynamics in team settings in areas such as communication, quality of work, time management and overall efficiency. The aim of the present study is to examine how a precrastinator's presence on a team affects key areas of team dynamics as well as performance outcomes by utilizing a sample of college students. Students were asked to complete a survey with demographic questions and a precrastination measure, followed by a Zoom interview where they were asked about their experiences working with precrastinators in team settings. Their responses were analyzed to identify common themes related to precrastinators' effects on team dynamics and students' attitudes toward working with them. Preliminary findings suggest that students' attitudes toward working with precrastinators are generally positive. Although some precrastinators can make their teammates feel rushed or overshadowed, most are perceived as reliable team members that produce high quality work and help motivate their teammates to stay productive. This study can contribute to the literature by investigating the understudied phenomenon of precrastination, particularly in team settings. The findings may offer insights that could help better understand how team dynamics and outcomes are affected by precrastination.

Abstract Name: Characterization of Tau and Amyloid- β Pathology in a Novel Mouse Model of Alzheimer's Disease

The general characteristics of Alzheimer's Disease (AD) include progressive neurodegeneration, cognitive impairment, and neuropathological features consisting of A β plaques, hyperphosphorylated tau, and neuroinflammation. Despite many available animal models, the majority are incapable of fully mimicking the complex pathologies seen in human AD. The recently developed a Novel mouse model expresses both A β and human tau pathologies, allowing for a more comprehensive representation of the disease. Our objective in the present study was therefore to characterize neuropathological changes in Novel mice compared with controls by means of immunohistochemistry. In detail, we quantified age-dependent differences in tau phosphorylation, A β deposition, microglial activation, astrocyte reactivity, complement activation, and vascular alterations within hippocampus and striatum. Immunofluorescent analysis using primary antibodies against AT8, Tau-217, 6E10, A β 1-42, IBA1, CD68, GFAP, and C3 showed intense colocalization of A β plaques and hyperphosphorylated tau in novel mice and increased microglial (CD68/IBA1) and astrocytic (GFAP/C3) activation compared with age-matched controls. Additionally, Collagen IV staining revealed vessel-associated pathology indicative of cerebral amyloid angiopathy. Altogether, novel mice are characterized by the presence of multiple convergent hallmarks of AD pathology, supporting their value as a translationally relevant model to study neurodegenerative mechanisms and therapeutic strategies.

Abstract Name: Nebi: Reinventing Mechanisms in Lighting Design

My bedside lamp design, Nebi, investigates how light can enhance story time for both children and readers. Through two physical mechanisms, I abstracted the features of a smart lightbulb to create an interactive lighting experience. The first, employs interchangeable colored acrylic disks to physically filter a standard lightbulb, demonstrating additive color relationships through physical action. The second, adapts the mechanism of a camera iris; twisting the lamp's top opens and closes vertical blinds, allowing children to directly observe how physical changes affect brightness. These features achieve the same function as a smart lightbulb, by allowing children to change the color and brightness, thus the mood, of the light. While smart, remote lightbulbs are convenient, these interfaces hide the mechanics of how light operates, preventing understanding. The tangibility of my design helps children develop a stronger cognitive experience when reading a book. My design process consisted of research, sketching, critiques, prototypes, computer-aided design, renders, and four functional, identical products. While designing, I closely focused on

manufacturability and sustainability with careful consideration of material, construction, and right-to-repair. The outcome of my work includes four fully functioning prototypes and digital renders. For NCUR, I propose to display one of my completed designs and a poster to display my design process within the Visual Arts session. My goal is to demonstrate how playful product design can support learning and imagination in everyday objects.

Abstract Name: Health Worker Resilience as a Driver of Health System Resilience in Kenya: A Mixed-Methods Study

Background: Health systems in southwestern Kenya, one of the most resource-limited and understaffed global regions, are frequently affected by community-level disruptions due to weather events, political violence, and economic crises that lead to adverse health outcomes in pregnant/postpartum women with HIV and their health workers (HW). This study aimed to examine predictors and mechanisms of HW resilience amid service disruptions and their potential impact on health system resilience. Methods: We conducted an exploratory sequential mixed-methods study in Kisumu County, Kenya in 2023-2025, utilizing the Job Demands-Resources framework. We integrated findings from qualitative data [4 focus groups (FGDs) with 29 HWs and 10 key informant interviews (KII)], and a cross-sectional survey among 200 HWs. FGDs/KIIs were analyzed using rapid thematic analysis; predictors of HW resilience were examined using multiple linear regression; and findings were triangulated and synthesized during the integration phase. Results: HW resilience was associated with professional quality of life ($\beta=-0.0964$, $p=0.0010$), compassion ($\beta=0.2348$, $p=0.0010$), higher levels of stigma ($\beta=1.0966$, $p=0.045$), being ≥ 51 years ($\beta=2.5671$, $p=0.012$), and having a university-level education ($\beta=2.9403$, $p=0.015$). Additionally, compassion, burnout, stress, financial stress, anxiety, trauma, stigma, emotion-focused and avoidant coping mechanisms, and adaptive performance methods were associated with increased depression scores, affecting resilience. HWs described significant work-related strain during crisis periods, noting heightened burnout, emotional fatigue, financial stress, and reduced motivation that interfered with their professional and personal lives. These stressors compromised HW's ability to provide consistent, high-quality care, weakening the system-level resilience. FGDs/KIIs participants emphasized a pressing need for resources to support their personal and professional well-being, seeking programs focused on coping strategies, time management, work-life balance, and emergency preparedness. Conclusion: Burnout, financial stress, and diminished professional quality of life collectively weaken individual health worker resilience and adversely affect adaptive capacity, critical to health system resilience and quality of care.

Abstract Name: Optimization of Learning Schedules Considering Individual Concentration

This study proposes a method for constructing personalized study schedules using mathematical optimization to maximize individual learning efficiency. We incorporate time-series data of individual concentration into the optimization problem. In recent years, the widespread proliferation of digital devices, such as smartphones and video games, has remarkably increased individual differences regarding concentration duration and the timing of peak performance zones. Consequently, it is no longer appropriate to uniformly apply general theories regarding concentration when formulating customized study schedules. To address this issue, our research proposes a novel approach that integrates time-series data of instantaneous cognitive states, obtained from Electroencephalography (EEG), into a mathematical optimization problem, thereby accurately reflecting unique individual characteristics. We formulate the scheduling problem based on a Mixed-Integer Programming (MIP) framework. Specifically, we first convert concentration data obtained from EEG into quantitative scores. We then set the maximization of the "total concentration score" for task allocation in each time slot as the objective function. Furthermore, by incorporating real-world constraints such as task deadlines and required durations into the model, we design it to construct highly practical schedules. Comparative analysis revealed that the optimized schedule utilizing EEG data yielded a significant improvement in the daily total concentration score compared to generally recommended study schedules. A notable finding is that during time zones where concentration is relatively low, the model selected an allocation that frequently switches task types, essentially fragmenting and dispersing tasks. This specific allocation was confirmed to effectively prevent the decline of concentration. These results demonstrate that optimizing based on an individual's fluctuating concentration, rather than adhering to conventional continuous task execution, can significantly improve learning efficiency. Future work aims to process EEG data with AI to create a continuous feedback loop, enabling the automatic construction of adaptive study schedules.

Abstract Name: Comparative Analysis of Eubacteria in Avian Excreta with Eubacteria in Porcine and Equine Feces on a Georgia Farm

This study presents a comparative analysis of the eubacterial communities in avian species versus pigs and donkeys, utilizing 16S Polymerase Chain Reaction (PCR) and Next-Generation Sequencing (NGS). The gastrointestinal tracts of animals harbor diverse and complex microbial ecosystems that play a crucial role in host health, physiology, and nutrition. Understanding the composition of these microbial communities across different host species is fundamental to veterinary science and microbial ecology. We hypothesized that significant differences would exist in the gut microbiota of avian hosts compared to mammalian hosts (pigs and donkeys) due to their distinct evolutionary paths, digestive physiologies and dietary habits. Fecal samples were collected from each animal group and processed. Eubacterial 16S rRNA genes were amplified using universal primers, and the amplicons were sequenced. Results indicate a taxonomic divergence between the

avian and mammalian gut microbiomes. The avian microbiota was predicted to have a lower proportion of Bacteroidetes, whereas, the microbiomes of pigs and donkeys would be dominated by Firmicutes and Bacteroidetes, consistent with a fermentative digestive strategy for fiber degradation. Furthermore, specific bacterial genera were found to be unique to each host type, suggesting a host-specific adaptation of the gut microbiota. These findings highlight the impact of host phylogeny and physiology on shaping the gut microbial ecosystem. The application of 16S PCR and NGS provides a powerful tool for elucidating these complex microbial assemblages. Further analysis of this data will provide deeper insights into the functional capacities of these distinct microbial communities and their co-evolution with their respective hosts.

Abstract Name: "Antioxidant" A Term Too Broad in the Context of Cancer

With an aim to demonstrate the mechanism-based impact of four antioxidants in glioblastoma temozolomide (TMZ) treatment, a systematic literature review was conducted examining how different antioxidants affect temozolomide therapy in glioblastoma. Antioxidants have been shown to induce resistance to treatment in many instances but enhance sensitivity in others. This research hypothesized that the impact correlates with the primary mechanism in action: scavenging reactive oxygen species (ROS) or modulating pathways. Three antioxidants with a single consistent impact on TMZ therapy, glutathione, curcumin, and resveratrol, were reviewed to identify their underlying mechanism. N-acetylcysteine (NAC), an antioxidant that has shown both impacts of either resistance or enhancement, was analyzed as two separate antioxidants based on these dual impacts. This highlighted the possibility of the antioxidant mechanism playing a key role in influencing the outcome of TMZ therapy. As a result, a correlation was identified between ROS-scavengers with inducing resistance and pathway-modulators with enhancing sensitivity, which provided evidence that antioxidants are contextually dependent on mechanism in action. This research may extend to other cancers treated with similar oxidative stress-inducing therapies, suggesting a broader applicability of the mechanistic categorization. However, future research is needed to understand the factors that determine whether an antioxidant will act primarily as an ROS-scavenger or a pathway-modulator to effectively control outcomes to TMZ therapy.

Abstract Name: Who Goes Abroad? A Psychological and Demographic Analysis of Study Abroad Intentions

This study explores the psychological and demographic factors that influence college students' intentions to study abroad. Prior research suggests that socioeconomic status (SES), gender, race/ethnicity, and academic standing play a significant role in determining who participates in international education among college students. Additionally, psychological variables such as motivation, personality traits, and self-efficacy have been shown to influence readiness and willingness to study abroad. This study builds on existing literature by using a quantitative survey-based approach to assess the impact of demographic characteristics, intrinsic and

extrinsic motivation, perceived barriers, intercultural self-efficacy, and Big Five personality traits on students' intentions to participate in study abroad programs. Using the Social Cognitive Career Theory (SCCT), the study conceptualizes intention as a function of self-efficacy beliefs, outcome expectations, and contextual influences, shaped by individual inputs such as personality and background. Data collection has begun with undergraduate students at James Madison University, and the aim is to finish data collection February 2026. Data will be analyzed using independent samples t-tests, one-way ANOVA, Pearson's correlation, and multiple regression. The study aims to identify the predictors of study abroad intention and to uncover barriers. Findings may inform the development of support systems and policy changes that broaden access to study abroad.

Abstract Name: How Gene Variations Affect Heart Health: Function of Gene Variants in Heart Disease

Alternative splicing allows a single gene to produce multiple proteins, playing a critical role in heart development and disease. Disruptions in this process have been linked to conditions such as heart failure. Our earlier studies have identified a gene variant of Mbnl1 (Muscleblind-like protein 1) in failing hearts generated by alternative splicing. The alternative splicing event of Mbnl1 produces a new gene variant without Exon 7 (a 36bp DNA fragment), which we termed as (Mbnl1- ΔExon7). Our earlier study has found out inhibition of Mbnl1 Exon 7 could protect stress induced cardiac cell death. Using mouse models, inhibition of Mbnl1 Exon 7 could further prevent the development of heart failure post myocardial infarction injury. However, the underlying mechanism between the Mbnl1 alternative splicing and its impact on cardiac injury remains unknown. This project aims to investigate how the Mbnl1 ΔExon7 isoform affects heart cells under stress. We will utilize bioinformatics prediction, targeted immune-precipitation to understand whether Mbnl1 variants could be differentially modified. We will further explore whether the Mbnl1 gene variants can have different impacts on cardiac cell death during stress when expressed in cultured cells. This research enhances our knowledge of alternative splicing in cardiac stress and offers hands-on experience in molecular biology techniques and data analysis. Findings from this study may contribute to the growing field of RNA-based therapeutics for heart disease.

Abstract Name: Identifying Early Sexual-stage Markers in Malaria Using Single-Cell Transcriptomics

The malaria parasite, *Plasmodium falciparum*, develops into sexual-stage gametocytes within the human host. The parasite develops across several morphologically distinct stages between a human and a mosquito host. Previous evidence suggests that all parasites descended from a committed schizont, the stage before division, also develop into the same sex. Despite this, there exists very little literature categorizing these early sexual drivers. In this poster, using single-cell transcriptomic data, slingshot analysis, differential analysis, and RNA velocity techniques, I attempt to identify early sex markers across *P. falciparum* strains during the stalk

developmental phase. First, a trajectory-based analysis was used to compare the genes driving sexual commitment between the NF54 strain and the E5 strain. Following a pipeline developed by previous literature, 8 female and 6 male gene candidates were found for E5. Only 1 gene overlapped between the E5 and NF54 gene candidates. I then combined both datasets to look at the same developmental area of the UMAP to look for genes that were differentially expressed in both the NF54 and E5 strains. To confirm the dynamics of the expression of these genes, RNA velocity was used on the NF54 dataset. Using RNA velocity dynamics modeling, it was found that relationships across strains not captured in trajectory analysis were recovered. Male gene markers for both NF54 and E5 were upregulated in the male lineage compared to the female lineage and vice versa for the female genes, confirming previous findings. Overall, this analysis identifies several promising sexual gene candidates that are conserved across strains, allowing for future study into sexual development in the malaria parasite.

Abstract Name: Barriers to Reintegration of Human Trafficking Survivors: Evidence from Tanzania

Tanzania is a source, transit, and destination country for underreported trafficking of men, women, and children, primarily for the purposes of forced labor and sexual exploitation. Despite the Tanzanian Government's recent advancements in combating human trafficking, little research has examined popular perceptions of trafficking survivors and, by association, the barriers to reintegrating trafficking survivors into their communities. Leveraging a vignette — a short story designed to depict a scenario, used to elicit participant attitudes — embedded in an in-person survey of 1,002 rural villagers in coastal Tanzania. I examine how five features of a trafficking survivor's experiences — (1) age, (2) wealth, (3) type of labor, (4) form of pressure, and (5) the relationship between the trafficker and the trafficked — influence the likelihood of an individual experiencing stigma or receiving support in their return communities. In addition to measuring participants' personal willingness to warn, help, and socialize with the survivor, they were asked to predict their community's treatment of the same survivor. Finally, we assessed the extent to which participants felt the survivor embodied the following traits: (1) selfish, (2) smart, (3) brave, and (4) untrustworthy. To examine these dynamics, I use regression analyses in R to model how variation across five key features of a survivor's trafficking narrative predicts both individual and perceived community responses. Results show that being trafficked into sex work rather than domestic servitude, returning with more wealth (as opposed to returning poorer), and being trafficked by relatives (as opposed to strangers) trigger alarm and reduce support, while the victim's age and the type of pressure they experience are less influential. The study also concludes that, regardless of randomization, individuals perceive themselves as playing a more active role in warning, helping, and socializing with the survivor than their community counterparts do.

Abstract Name: Concept-Based Language Instruction: Subjunctive is All About “Dominion”

This study interrogated the effects of a new approach to teaching the difficult-to-acquire grammatical structure of mood in Spanish as a second language (i.e., indicative and subjunctive): Concept-Based Language Instruction (C-BLI) (Poehner & Lantolf, 2024). Conventional rules-of-thumb teach phrasal “cues” to the subjunctive, which are linguistically inaccurate, therefore confusing, and also hard to remember. In contrast, C-BLI, which is rooted in Vygotskian Socio-Cultural Theory, presents students with scientific linguistic concepts that are abstract but linguistically complete. Several studies suggest that C-BLI can be effective for intermediate and advanced learners learning a variety of grammatical, lexical, and pragmatic concepts (see Poehner & Lantolf, 2024), but empirical studies of C-BLI for teaching mood have had mixed results, and almost all C-BLI studies have recruited intermediate and advanced learners. Our study filled two gaps by recruiting beginning learners and applying a new cognitive linguistic concept – “Dominion” (Vesterinen, 2013) – to explain mood. That is, our study taught beginning and intermediate-level Spanish students (n=29) at two US universities that mood choice is a matter of construing events as inside or outside of a conceptualizer’s “Dominion.” We analyzed 24 hours of in-class discussion, verbal explanations of students’ thought processes, written homework assignments, and tests. We evaluated how students developed conceptually during the C-BLI and what mediation (feedback) they required, and how each was impacted by proficiency level. We found that both beginning and intermediate students achieved significant conceptual development, using the concept of “Dominion” to motivate their mood choices. We also found that teacher mediation was required to attend to a variety of confusions about the concept. Students’ proficiency level did indeed impact the prevalence and nature of several of these conceptual confusions. Our study has implications for expanding C-BLI in beginning classes and for all instructors and learners wrestling with the complex concept of mood.

Abstract Name: NSF Advance’ Project RAISE ‘Day of Dialogue’ Series: Revealing Perceptions of University Representation

As of 2021, women make up 39.1% of the U.S. adult population who have obtained a bachelor’s degree, while men make up 36.6%, reinforcing the importance of female representation to scholarship (US Census Bureau, 2021). However, even as women demonstrate clear importance to the size, creativity, and diversity of the academic workforce, women’s academic underrepresentation in science, technology, engineering, and mathematics (STEM) is ever-growing (Blackburn, 2017). Research also suggests that higher education STEM environments can contribute to the underrepresentation of historically marginalized groups (Carlone & Johnson, 2007; Domingo et al., 2022; Ong et al., 2018). Recent data within Florida Gulf Coast University (FGCU) found that gender, race, and ethnicity inequities within STEM and overall faculty align with the previous literature, with women and BIPOC being underrepresented (OIR, 2022). In the purpose of addressing such systemic inequities, Project RAISE (Reveal, Amplify, and Implement Strategies for Equity) was created at Florida Gulf Coast University (FGCU) and received an NSF Advance Catalyst grant to complete such work (NSF, 2020). Project RAISE intends to conduct internal analysis and combat revealed inequities through three goals: 1) Collect and visualize patterns of representation and equity through an intersectional lens; 2) Educate key FGCU stakeholders about deficits in STEM representation and equity; 3) Engage stakeholders for strategy planning for enhanced diversity at FGCU. Within the project, the ‘Day of Dialogue’ Series was made to help accomplish the team’s second goal, involving faculty in discussions to

highlight educational inequities across student, staff, and faculty bodies. This conference proceeding will demonstrate how the Day of Dialogue Series can provide visualized data and involve stakeholders in improving environments that may contribute to inequity at FGCU. Furthermore, the activity's insights will be shared on utilizing qualitative methods to reveal educational inequities and improve the culture of higher education.

Abstract Name: Indigenous Gender Identity: Challenging the Lens of Colonial Epistemology

Western views of sex and gender have historically affected and shaped records of Indigenous gender practices. Traditionally, Western societies have viewed gender and sex to be binary(male/female), static, and physically self-evident. In the 1960s, philosophical, social, and feminist studies began reexamining the relation between Western society and gender, finding it to be a social structure founded in societal expectation and not biological certainty. In the wake of increased scrutiny over the epistemological foundations of gender, we can finally examine the inherent bias found not only in our own history but also in the gendered history of colonized nations. This colonial lens is most prominent in cultures such as the Indigenous North American tribes, where the written history of cultural practices only exists as colonial ethnography. In this study, we will analyze the colonial lens of Euro-American gender epistemology in relation to records of gender identity in different Indigenous North American tribes. By identifying and removing both the colonial and modern lenses of gender, this research shows the nuanced effects of indigenous culture, religion, and societal expectations on gender identity, presentation, and performance beyond ties to biological sex. By examining regional differences, this study demonstrates the complexity of gender as spiritual, situational, and interconnected.

Abstract Name: An Optimization Model for Emergency Patient Allocation with Fairness and Medical Compatibility

In urban emergency medicine, rapidly and accurately determining which hospital should receive a patient is a complex, life-critical decision. Conventional dispatch protocols typically direct patients to the nearest hospital to reduce travel time. While fast, this approach can lead to the overloading of certain hospitals, underutilization of others, and insufficient consideration of whether a hospital is medically appropriate for a given patient. To address these issues, this research proposes a new nonlinear optimization model – a mathematical decision-making tool – designed to balance three objectives simultaneously: assignment efficiency, hospital workload fairness, and medical compatibility. Few existing studies directly incorporate detailed clinical attributes into the assignment process, and our model adds value by explicitly integrating

these medical factors into its decision framework. The model consists of four main components. First, to ensure efficiency, it minimizes the total distance ambulances need to travel. Second, it monitors hospital burden and avoids assignments that would cause a sudden, unmanageable surge in a facility's workload. Third, it introduces a method for calculating medical compatibility. Patient attributes (age, gender, pregnancy status, consultation history, blood type, Rh factor) and hospital capabilities are represented as feature lists, and a standard scoring formula is then used to rate how well each hospital can meet each patient's needs. Fourth, the model measures fairness by examining how unevenly workloads are distributed across hospitals and works to reduce this imbalance. By adjusting the importance assigned to each of these components, the model enables decision-makers to flexibly prioritize speed, equity, or medical necessity depending on the situation. This presentation explains the structure and objectives of the model and outlines our plan to compare its performance with conventional distance-based methods using numerical simulations. In the long term, this research aims to support more balanced, transparent, and patient-centered decision-making in emergency transport systems.

Abstract Name: Isolation of Quercetin from Various Sources and its Radical Neutralizing Properties

Quercetin is one of the most abundant flavonoid compounds in the human diet, being found in various edible plants, and is among the most potent dietary antioxidants. Antioxidants prevent oxidative stress by scavenging free radicals that can cause cell death and therefore are critical in people's diets for maintaining health. We conducted extractions of quercetin from plant sources and commercially available supplements to assess the amount of extractable flavonoids and the radical scavenging ability of these extracts. We found that the total flavonoid content (TFC) significantly varied between each of the four supplements tested and that more flavonoids were extracted using microwave assisted extraction (MAE) versus a sonication method. The half maximal inhibitory concentrations (IC₅₀) of each of the samples indicating the ability to scavenge free radicals was also determined using a spectrophotometric assay. The amount of extracted quercetin in the supplements and plant sources allows for informed decisions about dietary and nutraceutical intake of antioxidants to help in the prevention of disease through non-pharmaceutical measures.

Abstract Name: Songs That Heal: The Effectiveness of a Music Therapy Approach for Treating Depressive Symptoms in Low-SES Adolescent Populations

Adolescence is a vulnerable stage of development, with nearly one in five teenagers in the United States experiencing at least one depressive episode before adulthood. Adolescents from low-income backgrounds face additional challenges that heighten their risk for depression. Traditional therapeutic approaches, while beneficial, often come with barriers such as high cost, limited access, and large discontinuation rates. These limitations give rise to interventions that are both effective and practical. Music therapy, defined as the

clinical use of music interventions for therapeutic goals, has shown success in improving emotional well-being and self-expression. This literature review evaluates the current scholarship regarding the effectiveness of music therapy for reducing depressive symptoms in adolescents from low-income backgrounds. There is also an implementation of an Anti Oppressive Practice theoretical framework in the thematic analysis of the literature. Findings suggest that music therapy can reduce depression, though more research with adequate methodology is needed. It is also time-efficient and affordable, making it more accessible for disadvantaged populations. The research suggests music therapy is a promising intervention for addressing gaps in mental health services for low-income adolescents, with possible implementation in underfunded schools and children's hospitals.

Abstract Name: Impact of Individualized Neuroanatomy and EEG Functional Connectivity on Primary Motor Cortex Excitability During Transcranial Magnetic Stimulation

Transcranial magnetic stimulation (TMS) is a non-invasive technique that targets specific brain regions through localized electric fields. The primary motor cortex (M1) is commonly stimulated due to its reliable elicitation of motor evoked potentials (MEPs), measurable via electromyography (EMG). Typically, the relationship between TMS-induced electric field intensity and motor cortical excitability is assessed through analysis of the MEP recruitment curve. While variability in TMS responsiveness has been associated with cortical oscillatory states, intrinsic brain states, and anatomical factors such as scalp-to-cortex distance, the detailed effects of individualized neuroanatomical and functional connectivity features on TMS outcomes remain unclear. In this study, we investigated the influence of individualized neuroanatomy and EEG-derived functional connectivity on motor cortex excitability during TMS. We recruited 20 healthy adults (8 women; mean age 28.3 ± 9.4 years), obtaining multimodal datasets including EMG recordings during TMS, resting-state electroencephalography (EEG), and structural magnetic resonance imaging (MRI) [1]. EEG analyses provided insights into the functional connectivity of M1, while MRI-derived anatomical models enabled accurate computational simulations of TMS-induced electric fields. Our results confirm that the relationship between motor cortex excitability and functional connectivity aligns with established literature. By integrating neuroimaging, electrophysiological data, and computational simulations, we expect to significantly improve predictions of individual M1 responses to TMS. These insights may enhance personalized TMS protocols, refine stimulation parameters, and reduce interindividual variability, ultimately improving the efficacy and precision of therapeutic neuromodulation.

Abstract Name: Laughing at the Sacred: Abstract

This paper investigates the use of religious satire as it is used to address the human condition regarding religion. To show these connections, this paper will look into two contemporary U.S. and British media. The British comedy Monty Python's: Life of Brian (1979) and the American animated sitcom The Simpsons (1989 – present day). More specifically, this comparison will dissect The Simpsons Season 4, episode 3: "Homer the Heretic" (1992). While both of these sources are western in origin, this does not mean that religious satire, or satire in general, is a western-only phenomenon. The purpose of this research is to demonstrate how, although these two Western countries utilize different satirical patterns in their works, they do not use their religious satire as a way to mock the religion itself, but rather the people who practice and follow it. Following the outline of the paper, the first topic that will be discussed is how each nation developed its use of this satirical form. Before leading into a rundown of the two media, looking at the satirical patterns they both use and how they relate to the human condition. Lastly, the paper will address the

controversies both had to go through in order for us to view and appreciate them today. Academic film reviews of the two chosen media and books on the history of religious satire will be used to support this paper.

Abstract Name: Cultural Coping as a Preemptive Filter: Challenging the Linearity of Insight-to-Intent in MENA College Students

The traditional model of mental health service utilization assumes a linear progression from psychological distress to Recognition of Need (insight), and subsequently to Intention to Seek Services. However, for historically marginalized populations, particularly Middle Eastern and North African (MENA) college students, this linearity is often disrupted. This research extends prior work that highlighted the critical gap between a MENA student's intention to seek help and their actual follow-through to counseling. This follow-up study investigates the critical collision between emotional resilience and cultural coping. MENA students are often socialized toward emotional restraint and reliance on "in-house" coping strategies (e.g., familial support, private management), which serve as mechanisms of resilience. We examine whether these culturally-aligned, strength-building strategies can unintentionally prevent students from translating good intentions into seeking professional mental health care. Using data from the 2023–24 Healthy Minds Study (HMS) dataset, our analysis will focus on MENA-identifying students who exhibit clinically significant psychological distress (i.e., insight) yet report no intention to seek services. We hypothesize that this decision to forgo care is driven not by traditional barriers (e.g., cost or access), but by the immediate selection of the preferred, culturally-validated "in-house" coping alternative. We will use survey-adjusted logistic regression, predicting the intention to seek services, with the core predictor being the students' measured preference for "in-house" coping. We anticipate this preference will emerge as a robust, negative predictor, demonstrating that cultural coping functions as a preemptive diversion from the formal care pipeline. This challenges the assumption that insight necessarily precedes intent, suggesting interventions must engage cultural values upfront to create effective and culturally-aligned pathways to care.

Abstract Name: 'You Know the Type': a Deconstruction of Misogynoir/Portrayals of Cruel Women in Danielle Evans' *The Office of Historical Corrections*

Danielle Evans' novella *The Office of Historical Corrections* (2020) is a masterclass in portraying flawed, complicated women who consciously make sacrifices to survive, without characterizing them as violent, unforgiving, or cruel. Misogynoir targets Black women throughout the narrative. Set contemporarily, the story follows the employees of the fictional Institute of Public History, an organization dedicated to truth and

justice. Cassie, the protagonist, works to correct misinformation, down to small details like the history of Juneteenth in an advertisement. The deuteragonist, Genie, is her long-term rival who shares a passion for righting falsifications, even if the average person views her as pedantic and invasive. Cassie and Genie are pitted against each other by IPH; Genie conducts the controversial fieldwork—Cassie interfaces with the public as the calm, “non-threatening” Black woman. People view Genie’s methods of correction as crass and unnecessary, such as when she challenged the celebratory portrayal of George Washington in a play that sounds suspiciously like *Hamilton* by including damning facts about his slave owning past. After Genie is fired from IPH, she reimagines herself as an investigative journalist, and the two reunite to research the complicated history of Josiah Wynslow, a Black man who lived in a rural Wisconsin sundown town, Cherry Mill, in the 1930s, and was supposedly killed by a racist mob. Together, they discover that Minerva Wynslow, Josiah’s sister, fled her life in Chicago to live in Cherry Mill, where she passed as white. Minerva’s choice to leave her family behind is easily misinterpreted as cruelty. Even in death, Minerva can’t escape judgment. However, he chose to reinvent herself and assimilate into white society, to live safely in a world that wants her to feel pain. Ultimately, Evans portrays the cruel reality Black women face—one where they must sacrifice dignity and honor to survive.

Abstract Name: The Barriers and Successes of Accessing Mental Health Services for LGBTQ+ Students with Disabilities in Higher Education: A Nationwide Analysis.

Individuals with disabilities within the LGBTQ+ community often face more stigma and social barriers, which may result in poorer mental health outcomes and reduced overall well-being (Argenyi et al., 2023). For this community, there may be an increased need to access mental health services to address their concerns, yet institutions may not cater to the specific intersectional identities of this population. Our team sought to find answers to the following questions: 1) What are some of the experiences of LGBTQ+ individuals with disabilities when it comes to accessing mental health services, and 2) What are some recommendations that services can implement for future students? Utilizing Qualtrics, we created a pilot survey exploring how the target population currently perceives accessibility to mental health services and assess their general feeling of belongingness to their communities. Specifically, questionnaires inquired about the types of services currently available, their effectiveness, and the overall campus atmosphere, including feelings of belongingness. Participants had the opportunity to enter a raffle for a chance to win one of twenty \$25 Amazon gift cards. Recruitment started in October and will continue till the end of December via cold emailing, email chains, and physical fliers. Our team plans to analyze results beginning January 2026. Preliminary findings of the survey revealed that many participants indicated mental health needs (depression, anxiety, etc.), aligning well with previous research. Participants who have attempted to access mental health services at their institutions have expressed barriers within these three themes: a lack of accessibility, a lack of representation, and financial constraints. Using data from our survey, we plan to interview volunteer participants to learn more about individual experiences and to gather feedback on existing mental health resources. We hope to develop action plans or initiatives for college mental health services to improve accessibility for this population.

Abstract Name: Tennis Match Prediction Project

In the past, sports predictions were based on expert opinions, however with the development of data analytics models and more technology resources, there are more techniques available on predictions which analyze historical data and player statistics. In order to reach these predictions, I create a project that uses historical data to find a probability of who is more likely to win based on past performance and predicts the winner based on that probability, apply machine learning algorithms to improve match outcome predictions and provide perceptions for coaches by identifying key factors influencing match outcomes. Among the models tested including Decision Tree, Logistic Regression, Random Forest, Random Forest performed the best overall, achieving the highest accuracy and balanced performance across precision and recall. Logistic Regression also showed stable results, while the Decision Tree tended to overfit and performed worse on unseen data. Additionally, the performance of the best model was clearly better than random guessing, which would only achieve chance-level accuracy. When compared to the simple method of always picking the higher-ranked player as the winner, the machine learning models did improve, but the margin was not significant.

Abstract Name: Experimental Evaluation of Calcium Lignosulfonate for Dust Suppression on Rural Unpaved Roads: A Sustainable Approach in Impacted Areas in La Peña, Veraguas, Panama

Panama has a significant percentage (approximately 58%) of its road system unpaved, creating a significant problem due to dust emissions from vehicular traffic and wind, particularly during the dry season. Residents living near these roads must remain with their doors closed to avoid dust contamination inside home. This project proposes the use of calcium lignosulfonate as a sustainable method to improve an unpaved road in La Peña, a small town in the province of Veraguas, Panama. From an engineering perspective, the road's unstable surface generates excessive dust, reduces durability, and performs poorly under traffic and weather conditions. Traditional maintenance methods, such as frequent watering or gravel replacement, are costly, temporary, and environmentally unsustainable, highlighting the need for an innovative solution. To address these challenges, a combined laboratory and field-based approach is applied: previously extracted soil samples from the road are characterized and treated with calcium lignosulfonate; subsequently, compaction and strength soil laboratory tests such as modified Proctor, direct shear, and permeability are conducted to determine physical and mechanical soil properties of the treated specimens. Based on preliminary laboratory results, a pilot application is implemented on a 30 m long unpaved road segment near an affected public high school in la Peña, allowing measurement and monitoring of PM_{2.5} in the air, assessing the product's performance in dust suppression under real traffic and environmental conditions. Laboratory and field tests are expected to demonstrate that applying calcium lignosulfonate to an unpaved road surface improves soil particle bonding, stability, and compaction; reduces dust emissions; and decreases the need for frequent maintenance. Therefore, the anticipated outcomes highlight the potential of calcium lignosulfonate as a cost-effective, viable solution for unpaved road dust suppression, thereby increasing mobility, public well-being, and overall quality of life in rural communities in Panama.

Abstract Name: Using Artificial Intelligence to Satisfy Generalized Use Cases

The research started when the FCC proposed new rules to reduce cyber risk for emergency alerting systems. Many regulations, once adopted by the Commission, are then supplemented based on new developments in the field. These proposed rules are put out for public comment, after which they cannot be altered until a new record accumulates and the full Commission acts. The research results help ensure that proposed rules are informed by the best information currently available, a process that exceeds the capacity of most regulatory agencies. The student research team developed an AI application using RAG techniques that fine-tunes a large language model using vector database methods and a custom language set. The application includes a chatbot front-end that responds to prompts in a way that accounts for new developments in the field, thereby helping the regulator's limited staff consider a wide range of sources from academia, industry, and government. The team's research can help the regulator improve upon existing policies to improve emergency alerting reliability and security based on recent developments in alerting technology as expressed in the custom language set and other relevant sources that the application identifies. This phase of the project is complete and will be demonstrated at the conference. The application that the student researchers created can be applied to any use case by altering the custom language set. The student researchers are now working with an external client to apply their research to the hospitality sector. This research, driven by a new set of custom sources, will help the client better use customer feedback to improve their service and products. This research will help the team learn the extent to which the research product can be generalized to a new sector.

Abstract Name: Prenatal cannabinoid exposure causes memory deficit through altered glutamate receptor function

Prenatal exposure to cannabinoids (PCE) has increased substantially alongside the growing legalization and use of cannabis, a trend projected to continue. Mounting evidence links PCE to persistent neurodevelopmental impairments, especially in learning and memory. Despite growing concern, no therapeutic strategies currently exist to address the cognitive dysfunction associated with PCE. This study investigates how PCE affects the single-channel properties of synaptic AMPA (α -amino-3-hydroxy-5-methyl-

4-isoxazolepropionic acid) and NMDA (N-methyl-D-aspartate) receptors—critical mediators of excitatory neurotransmission and synaptic plasticity. To elucidate the mechanisms underlying AMPA and NMDA receptor dysregulation, pregnant Sprague Dawley rats received either sesame oil or 5 mg/kg of Δ9-tetrahydrocannabinol (THC) via oral gavage from gestational day 5 through postnatal day 9. Electrophysiological analyses were performed on hippocampal synaptosomal AMPA receptors from adolescent offspring (postnatal days 40–50) in control and THC-exposed groups. PCE offspring demonstrated a pronounced reduction in AMPA receptor open probability and altered single channel burst dynamics compared to controls. NMDA receptor activity was also disrupted, reflecting broad impairments in glutamatergic signaling. Collectively, these findings indicate that prenatal THC exposure alters both AMPA and NMDA receptor channel kinetics, likely compromising synaptic plasticity mechanisms such as long-term potentiation (LTP). Given the central role of AMPA and NMDA receptors in memory processing, these PCE-induced receptor alterations may underlie the learning and memory deficits observed in affected offspring. This study offers vital mechanistic insights into synaptic dysfunction following prenatal cannabinoid exposure and highlights the urgent need for targeted interventions to mitigate its neurodevelopmental consequences.

Discipline: Dance

Authors:

Abstract Name: Moving Toward Healing: Dance-Specific Approaches to Psychological Well-Being

While physical activity is widely known to support mental well-being, this research explores how dance-specific movement offers psychological benefits that go beyond those of typical exercise. Through an interdisciplinary lens, this project examines how structured dance technique, improvisation, choreography, and Dance Movement Therapy (DMT) support emotional, cognitive, and social health. DMT uses movement as a therapeutic tool to help individuals express emotions, develop mind–body awareness, and regulate stress. Research in the field shows that dance allows people to release emotions, spark creativity, and build confidence through both guided and spontaneous movement. This project also includes a practical performance component to investigate how movement qualities influence mood and personality. By analyzing improvisation sessions, choreographic processes, and the original dance work created for this research, the study observes how dancers communicate internal emotional states through dynamics, tension, rhythm, and spatial choices. These embodied explorations demonstrate how movement can shape and reflect one's emotional experience in real time. Beyond emotional benefits, dance has been shown to strengthen memory, attention, and overall cognitive function across age groups. It also promotes social connection through shared movement experiences, increasing feelings of community and belonging. These combined effects suggest that dance may be a powerful tool for addressing rising rates of stress and generational anxiety, especially among young people. The findings of this research highlight the unique psychological value of dance and suggest that dance-based programs may be beneficial within schools, community settings, and wellness initiatives. By combining scientific research with lived, artistic exploration, this project argues that dance-specific movement should be recognized as an important resource for supporting mental health and fostering resilience.

Abstract Name: The Art of Drew Struzan: More than Movie Posters

Drew Struzan, despite a difficult upbringing with little parental love, found solace in creativity and art from a young age. Using basic materials, he honed his skills and attended ArtCenter College of Design in 1965, where he met his future wife. Balancing freelancing and college to pay for school, Struzan graduated after six years. His career took off with album covers and later movie posters, gaining fame for his work on "Star Wars: A New Hope." Known for capturing the essence of films in his distinctive style, Struzan worked on various iconic projects like Star Wars, Indiana Jones, and Back to the Future. Despite struggles with the business side, he remained dedicated to his craft until retiring in 2008. His battle with Alzheimer's disease was announced in 2025, leading to his passing. Struzan's legacy as a legendary artist in hand-painted movie posters continues to be celebrated in the entertainment industry, with fans hoping for a new talent to emerge while honoring his memory.

Abstract Name: How Antigen Delivery Route Shapes the Development of Cross-Reactive Mucosal Immunity to Influenza

Influenza viruses undergo frequent antigenic shifts, making them prime targets for the development of a universal vaccine that provides long-lasting broadly protective immunity with only a few doses over a lifetime. Such a vaccine would reduce public health costs, increase vaccination coverage, and lessen the need for annual reformulation of seasonal vaccines. Traditional systemic influenza vaccines offer limited protection compared to the broader antibody responses developed by natural influenza infection in the respiratory tract, suggesting that the route of antigen delivery may influence immune breadth. To test this hypothesis, we compared systemic and respiratory delivery of the influenza antigen H1_{CA09} in mice using a replication-deficient adenovirus serotype 5 vector (Ad5). Intranasal immunization uniquely induced the development of antigen specific IgA antibodies at the site of viral entry, which cross-reacted with H1 protein from distantly related strains of influenza including the ancestral strain PR8. To test whether the cross-reactive antibodies provided functional protection, we next challenged identically primed and boosted mice with a sublethal dose of PR8. Notably, intranasal immunization enhanced viral clearance and significantly reduced viral morbidity, pulmonary inflammation, and fibrosis in comparison to intramuscular immunization in a heterologous challenge. In summary, these findings support that intranasal delivery of influenza antigen

is critical for the development of strain cross-reactive mucosal immunity, and suggests that local antigen delivery should be considered in the development of “universal”, broadly protective, influenza vaccines.

Abstract Name: Understanding How Teachers Form Expectations of Future Students

There are many factors that contribute to teachers’ expectations for their students. Some of these factors include gender, diagnostic information, and valence of background information about the student. This study addresses a research gap by examining the role of diagnostic information in shaping teachers’ expectations for future students in the United States, as well as the interaction with student gender and prior academic and behavioral information. This study aims to gain a better understanding of how information a teacher receives prior to meeting a student can impact their expectations of students’ academic performance, behavior, and social interactions. Participants were recruited using Prolific and included 140 current kindergarten through twelfth grade teachers living in the United States at the time of the survey. Each teacher read one of eight randomized vignettes describing an imaginary student to be placed in their classroom for the upcoming school year. Three independent variables were manipulated between the vignettes, gender (male/female), background information (positive/negative), and disability status (504 plan due to ADHD or asthma). Participants then answered Likert-scale style questions adapted from three established measures to determine teachers’ academic and non-academic expectations of the student, including their perceived conflict and closeness with the child and perceived behavioral control of the child. Survey responses will be analyzed using SPSS to answer the research question: How do gender and diagnostic information about a future student impact teachers’ expectations of the student’s academic achievement and teacher-student relationship development?

Abstract Name: The Fourth Amendment on ICE: Unlawful Detentions and Workers Rights

This paper examines the constitutional limits of immigration enforcement in the workplace by applying the legal framework established in *INS v. Delago* to the ongoing class actions of *Noem v. Vasquez-Perdomo* and *Escobar Molina v. Department of Homeland Security*. In considering the Fourth Amendment standards governing workplace warrants, probable cause, and seizures, this paper concludes that current Immigration and Customs (“ICE”) actions are clearly unconstitutional. The paper initially discusses when warrants are needed and the requirement that they identify individual suspects or are designed to gather reasonable suspicion of specific suspects. Delgado also articulates limited circumstances for immigration officers to operate without warrant. The paper then turns to probable cause, as it is based on the totality of the circumstances governing the encounter between immigration officers and individuals. Delgado prohibits officers from detain or physically move an individual with generalized suspicion, the officers must have individualized reasonable suspicion. The paper then defines what constitutes a seizure in a workplace setting and how that standard has evolved over time. The majority in Delgado concluded that some workplace

surveys conducted by immigration officers do not restrain the workers liberty and therefore do not constitute a Fourth Amendment seizure or detention. The dissent countered that the intimidating presence of the Immigration and Naturalization Service agents at one's workplace would make a reasonable person feel free that they were unable to leave or deny questioning, therefore making it a Fourth Amendment violation. As the law has evolved, the determination of a workplace seizure is fact specific. Applying this framework to plaintiffs in Vasquez and Escobar, this paper concludes that ICE agents are violating workers Fourth Amendment protections.

Abstract Name: Understanding the Differential Production of Antibiotics from Soil Bacteria from Different Locations

This research examines how bacteria found in children's playgrounds differ from bacteria collected in a less-treaded wooded area. The purpose of the study is to test how bacterial isolates from three different soil locations respond when challenged against ESKAPE safe relatives. Understanding these differences is important because identifying the bacteria present in specific environments and observing their characteristics can help categorize them more accurately. Three soil samples were collected: SS1a from a hill where children frequently played, SS1b from the playground mulch, and SS2 from a forest area. Samples were taken 1–4 inches below the surface to capture soil with the most environmental contact. In the lab, each sample underwent soil dilutions, was plated onto agar, and incubated at room temperature for 48 hours. Colonies were then identified and counted to calculate colony forming units (CFU). Colonies with unique characteristics were transferred to fresh agar plates and incubated for another 48 hours. These isolates were then tested on bacterial lawns of ESKAPE safe relatives (non-pathogenic bacteria), including *E. coli*, *Staphylococcus epidermidis*, *Enterococcus raffinosus*, and *Pseudomonas putida*, with *Enterobacter aerogenes* and *Acinetobacter* added later. After 48 hours of incubation, plates were examined for zones of inhibition indicating antimicrobial activity. Colonies showing inhibition were isolated, streaked onto new plates, and incubated again for further characterization. Additional identification of strains will include gram staining, the catalase test, and DNA amplification. The clearest zone of inhibition was found on *Staphylococcus epidermidis* in SS1a, then two unclear possible zones appeared in SS1b, and no inhibition zones were observed in SS2. These results suggest that bacteria from the hill near the playground exhibited the strongest antimicrobial properties. A unique observation was the wide variation in colony appearance and the change in odor in SS1b, which shifted from putrid to coffee-like and then back to putrid over time.

Abstract Name: From Classroom to Caregiving: A Model for Student Learning in Dementia Care

Introduction: Healthcare providers are often not prepared to care for individuals living with dementia and their caregivers. To ensure positive patient outcomes, all healthcare professionals should receive dementia-specific training. Compounding the challenge is that few university students are interested in healthcare careers working with older adults. Universities play a key role in addressing this shortage and fostering interest in geriatric care. This project aims to increase student knowledge and skills for working with older adults with dementia and supporting caregivers. To address this need, an interdisciplinary, multi-instructor service-learning course and The Healthy Brain Club, a dementia-specific respite, were developed in Spring 2025. Through the course, students engage in coursework and then plan and implement evidence-based activities for people living with dementia at the Healthy Brain Club. **Methods:** Students complete dementia knowledge and attitudes surveys at the beginning of the semester, at completion of classroom learning, and at the end of the semester after working at the respite. Students also submit semi-structured reflections midway and at the semester's end. Reflections from two semesters were coded using thematic inductive analysis. Further analysis will explore associations between students' initial dementia experience and assessment scores. **Results:** Five primary themes emerged: 1) Students report increased confidence and comfort working with people living with dementia and caregivers, 2) Both course sections are essential for building skills and knowledge, 3) Awareness of career opportunities broadened, 4) Students valued interdisciplinary collaboration, and 5) They recognized the caregiver role as crucial and expressed a desire to support caregiver wellbeing. **Conclusion:** The combination of coursework and applied learning greatly contributed to students' knowledge and interest in dementia care. Building relationships and managing the respite gave students ownership rarely felt in volunteer roles. This course/respite model is proving successful in increasing knowledge and interest in dementia care.

Abstract Name: Visualizing Plasma Flow and Secondary Ionization in Constricted-Anode Geometries Using Multi-Dimensional Particle-In-Cell (PIC) Simulation

Constricted-anode plasma sources generate locally intensified electric fields that enhance ionization near the anode, making them valuable in propulsion and laboratory plasma systems. However, the narrow geometry produces complex charge accumulation and secondary ionization effects that remain difficult to measure experimentally. To address this challenge, our research develops and applies a multi-dimensional Particle-in-Cell with Monte Carlo Collisions (PIC-MCC) simulation of a DC discharge in 1-D, 2-D, and 3-D configurations that model a constricted-anode device. PIC-MCC is a first-principles method that tracks electrons and ions individually while computing self-consistent electric fields and incorporating energy-dependent collision processes. This approach enables direct visualization of plasma flow behavior, species-specific particle motion, sheath formation, charge buildup, and electric potential structures—features that are often inaccessible to physical diagnostics. Throughout this project, we have constructed 1-D, 2-D, and 3-D PIC models; implemented energy-dependent cross-section tables; generated maps of electron and ion density; and produced detailed visualizations of electric fields and potentials. Our simulations consistently show strong electron accumulation in the anode region, leading to steep electric-field gradients that trigger secondary ionization cycles. In 3-D, geometric focusing intensifies this effect, increasing particle density, local heating, and the overall ionization rate. These insights demonstrate the utility of PIC modeling for revealing plasma behaviors that cannot be directly observed. Ongoing work focuses on re-optimizing the 3-D solver to more accurately capture secondary-ionization physics, improving predictive capability for the design and operation of future constricted-anode plasma sources.

Authors:

Abstract Name: Enhancing Anaphylaxis Risk Assessment through Machine Learning: A Focus on Egg Allergens

This study aimed to improve the accuracy of anaphylaxis risk prediction in pediatric patients with egg allergies through the use of advanced machine learning models. Traditional clinical assessments relying on IgE thresholds, patient history, and skin-prick results typically achieve only 50–60% accuracy, leaving substantial uncertainty in evaluating whether a child might experience a severe reaction. To address this gap, three predictive models—generalized Linear Model (GLM), an Ordinal Regression model, and an XGBoost gradient-boosting model—were developed and compared. These models were trained on a preprocessed public dataset containing immunological markers such as Gal d 1– and Gal d 2–specific IgE levels, total IgE, skin prick test wheal sizes, symptom severity history, and relevant demographic variables. The dataset was cleaned, normalized, and divided into training and testing subsets before being used to generate both categorical severity predictions (Anaphylactic, Sensitized, Tolerant) and continuous allergen severity scores. XGBoost demonstrated the strongest performance of the three, achieving an Area Under the Curve (AUC) of 97% and a Mean Absolute Error (MAE) of 11.3. Compared to GLM and Ordinal Regression—both of which showed difficulty modeling higher-severity reactions—XGBoost was better able to capture nonlinear patterns, such as interactions between specific IgE biomarkers and past reaction history. These findings suggest that machine learning, particularly ensemble-based approaches, has meaningful potential to enhance clinical decision-making by offering more accurate and individualized risk predictions. With more reliable tools, clinicians may be better positioned to identify high-risk patients, reduce unnecessary food challenges, and tailor intervention strategies to minimize the likelihood of severe anaphylactic episodes.

Abstract Name: Role of Schwann Cell Monocarboxylate Transporters in Peripheral Nerve Regeneration

Monocarboxylate transporters (MCTs), specifically MCT1, MCT2, and MCT4, are the primary transporters for lactate, pyruvate and ketone bodies in Schwann cells. These transporters play critical roles in many cellular processes, including metabolism, myelination, and peripheral nerve regeneration. Our laboratory and others have previously shown that removing MCT1 alone from Schwann cells leads to hypomyelination, disrupted lipid metabolism, and reduced motor end-plate innervation. Surprisingly, we found that selective ablation of MCT1 from Schwann cells did not impact nerve regeneration. Since Schwann cells also express MCT2 and MCT4, our hypothesis is that these two closely related transporters are able to partly compensate for the loss of MCT1. To assess the role of all MCTs, we obtained mice with selective ablation of MCT1, MCT2, and MCT4 from Schwann cells, termed P0-Cre:MCT TripleFlox mice. These mice do not develop peripheral nerve abnormalities, at least during young adulthood. P0-Cre:MCT TripleFlox mice and littermate controls (i.e., WT:MCT TripleFlox mice) underwent sciatic nerve crush and recovery was followed for six weeks by electrophysiology, behavior studies, and histology. By electrophysiology, there was incomplete recovery of conduction velocity (56.5% of pre-crush values in P0-Cre:MCT TripleFlox mice, as compared to 78.6% in WT:MCT TripleFlox mice, $p < 0.05$). Impaired recovery was also seen by behavior, with significantly impaired recovery of toe spread index ($p < 0.0001$) and horizontal ladder walk ($p < 0.01$), and

histology, with significantly reduced neuromuscular junction (NMJ) reinnervation ($p < 0.01$). We also obtained primary Schwann cell cultures from these transgenic mice and found reduced expression of genes important for regeneration, including c-Jun (reduced 32%, $p < 0.05$) and FGF2 (reduced 50%, $p < 0.05$). Our findings demonstrate that knockout of all MCTs from Schwann cells impairs the capacity of peripheral nerves to regenerate, at least partly due to inability to express critical regenerative transcription and growth factors.

Abstract Name: Space to grow: Development and implementation of mixed-method assessment tools to assess occupancy, utilization, and interaction patterns of informal learning spaces in the JMU biology department

Informal learning spaces are taking on an increasingly significant role in university settings to enhance the student experience. These spaces offer students learning-related activities outside the traditional classroom, fostering socialization and community. While prior research has demonstrated the value of informal spaces such as institutional learning commons and libraries in benefit to students' academic success and experiences, less is known about the impact of and student engagement in smaller unstructured community spaces (e.g., atriums, study rooms). Further, the absence of systematic methods for evaluating such spaces limits empirical decision-making and resource allocation. This case study uses the "BioCommons" at James Madison University to examine students' engagement in and perceptions of an informal departmental learning space. A mixed methods approach was taken combining qualitative observations of visitor activities with surveys for understanding their usage and perceptions of the space. Since fall of 2023, 1468 unique observations were conducted by trained student researchers providing data on visitor ($n=13,189$) actions, interactions, and resource usage, which were coupled with 510 closed- and open-item surveys lending insight to visitor backgrounds and perceptions of the space. Results have documented the utility and benefit of the departmental space in facilitating alone and group learning, relaxation, and community building, as well as access to student- and faculty-led programs and resources viewed to help offset barriers commonly associated with college student success. Preliminary findings of this ongoing study add to our understanding of how to monitor informal learning spaces and their contributions to the academic and personal growth of college science students.

Abstract Name: Seeing Science Differently? Using Eye Tracking Technologies to Explore How Neurodiverse and Neurotypical Biology Students Read Graphical Displays.

In the sciences and our everyday lives, graphs are essential tools for the communication of complex data in a more accessible and actionable form. As a result, graph literacy – the ability to interpret and critically engage with graph data – is regularly highlighted as a core competency in undergraduate science. Despite a growing catalogue of research identifying student challenges in graphing and beneficial graph instruction methods in college science, there is little known as to how neurodiverse learners engage with graph data. As an estimated 10% to 30% of postsecondary students in the US may be neurodivergent, understanding if learners of varying cognitive backgrounds “see” and make sense of graphical displays differently is of importance to inform inclusive teaching strategies. This exploratory study employed eye tracking technologies and cognitive interviewing to comparatively examine how neurotypical (n=21) and neurodiverse (n=22) biology majors read and interpret graphs. Participant eye movements were recorded as they completed 14 graph-based tasks of varying complexity drawn from textbook and everyday sources. Following the eye-tracking session, participants completed semi-structured “think aloud” interviews focused on their experience with and decision-making processes in graphing. Preliminary quantitative and qualitative results from the eye tracking data indicate that students across cognitive groups direct their attention and visual search patterns comparably when completing tasks with lower complexity graphs; however, variation in strategies were observed as a function of cognitive condition when interpreting more complex graph displays. Self-reports gathered from the interviews highlight similar levels of use and confidence as well as decision-making patterns in graphing between cognitive groups, while neurodiverse students also often identified their condition may impact how they make sense of graphs. Findings from this novel pilot project have the potential to inform inclusive teaching and data communication practices.

Abstract Name: The Effects of Fishing Spider *Dolomedes triton* Silk Cues on Defensive Behaviors and Predation of Aquatic Beetles (*Peltodytes* sp.)

The six-spotted fishing spider, *Dolomedes triton*, is a semi-aquatic predator that detects prey through vibrations on the water surface. These spiders also deposit hydrophobic silk in water that may alert prey to their presence and induce adaptive antipredator behaviors. If so, silk may function as an enemy-avoidance kairomone. Alternatively silk could function as a trip-wire to extend the sensory detection of prey by the spider and enhance prey capture. We tested these contrasting hypotheses using the aquatic beetle, *Peltodytes* sp. We measured shifts in beetle behavior and predation by juvenile spiders with and without the presence of *Dolomedes* silk. *Peltodytes* are benthic but must surface regularly to breathe, which leaves them momentarily vulnerable to predation at the surface. We measured the number of times the beetles (N = 119) performed this action in arenas containing or lacking silk, predicting that they would limit surfacing in the presence of *Dolomedes* silk if they could detect it. We also measured *Dolomedes* (N = 59) ability to capture *Peltodytes* in the presence or absence of silk, predicting that the spiders would be less successful at capturing beetles that were aware of their presence through silk cues. The beetles showed a significant change in behavior in the presence of silk, however, their surfacing increased rather than decreased in the first 4 minutes of trials in

arenas containing silk. Spiders were also significantly more successful at capturing beetles in the first 4 minutes of trials in silk-inoculated arenas and attacked beetles earlier when silk was present. Detection of silk apparently initiated escape behaviors of beetles, thus functioning as an enemy avoidance kairomone, however, increased activity was maladaptive within our testing arenas and more frequent surfacing enhanced detectability by spiders and led to increased predation.

Abstract Name: Microhabitat usage and symbiotic dynamics of a shell-dwelling cichlid (*Neolamprologus similis*)

Aquatic ecosystems promote variable microhabitats which in turn support dynamic biotic assemblages. One such microhabitat involves gastropod shells and the dependence on these microhabitats for breeding success in shell-dwelling cichlids native to Lake Tanganyika in East Africa. Once a microhabitat is selected by a male-female pair, both parents will care for the nest and eggs until the young are developed enough to leave the shell. This research aims to quantify how parental division of care influences offspring quality and developmental timing in the shell-dwelling cichlid *Neolamprologus similis*. Mating pairs of *N. similis* will be introduced to study tanks to assess shell selection, mating success, male-female brood care division, brood size, and larval development. Parental roles and the duration of care provided by each individual will be systematically recorded at specific intervals throughout the day. Data will be analyzed using generalized linear models for hatching/survival rates and time-to-event analyses for developmental timing. Insights from this work will inform conservation strategies for shell-dependent fishes and clarify the ecological consequences of parental workload partitioning within the species.

Abstract Name: Modeling the Dark Matter Halo with Rotational Dynamics

Dark matter remains one of the most significant unresolved questions in modern astrophysics, accounting for the majority of the universe's mass while remaining undetectable through direct electromagnetic observation. It is traditionally described as forming a diffuse, roughly spherical halo surrounding galaxies, providing the gravitational influence needed to explain why stars orbit faster than visible matter alone would permit. However, this conventional model may oversimplify the actual structure and behavior of dark matter. This project explores the theoretical possibility that dark matter may instead form a ring-like structure beyond the visible boundary of a galaxy, stabilized through rotational motion and gravitational interactions within the surrounding halo. In this framework, dark matter is also considered to potentially exert a weak repulsive

influence on regular baryonic matter, which could contribute to the separation and maintenance of distinct structural regions. Drawing on analogies to rotating fluid systems, such as atmospheric vortices, the project examines whether similar dynamical principles could apply on galactic scales. To evaluate this hypothesis, we will develop and run computational simulations in Python that model dark matter as a collection of particles influenced by gravity, angular momentum, and a tunable interaction term representing the proposed repulsive effect on baryonic matter. By varying mass density, velocity dispersion, and rotational characteristics, the model will test whether a stable ring-like structure can form and persist over time. While theoretical, this study aims to expand how dark matter distributions are conceptualized and may suggest new possibilities for interpreting galactic dynamics and observational data.

Abstract Name: Assessing miR-375 Targets and their Effects on Small Cell Lung Cancer Progression

Small cell lung cancer (SCLC) is an aggressive form of lung cancer often diagnosed in later stages when prognosis is poor. The mechanism behind SCLC metastasis remains unclear, though it is known that cellular plasticity is a driving force behind tumor cells transitioning between different states and promoting cancer progression. Previous studies have revealed miRNAs (miRs), small non-coding RNAs that regulate gene expression, as biomarkers that may play a role in SCLC progression. Our lab has previously shown that miR-375 expression is higher in advanced stage SCLC patients compared to control patients. However, the miR-375 role in this cancer is unclear. Characterization of SCLC cell lines for miR-375 expression has revealed that most SCLC cells have high expression of miR-375. In this study, we investigate the possible targets that drive SCLC progression. The H1048 cell line, a SCLC cell line with low miR-375 expression, was selected and transfected with an overexpressing miR-375 (oe375) or a control (Ctr) plasmid. RNA-seq and proteomics were performed and analyzed through IPA to uncover deregulated pathways involved in SCLC cell plasticity. Alamar blue, MTS, and colony assay were used to assess cell proliferation. Western blot, and RT-qPCR were used to evaluate protein and mRNA levels. Our study shows an enhanced cell proliferation in oe375 cells. Western blot analysis revealed an increase of E-cadherin and a decrease in YAP1 and Twist1 expression in oe375 cells compared to Ctr, suggesting a shift toward an epithelial phenotype. YAP1 is a direct target of miR-375. We hypothesize that miR-375 induces epithelial phenotype by targeting YAP1. We plan to re-express YAP1 in oe375 cells to validate this hypothesis. A second stable cell line was created to validate these data and provide further insight into how miR-375 overexpression drives cell growth and an epithelial phenotype.

Abstract Name: Embodying the Game: Using Game Design Theory to Analyze Walter Tevis' The Queen's Gambit

Walter Tevis's novel *The Queen's Gambit* follows the orphaned chess prodigy Beth Harmon. On her journey to conquer the chess world, Beth battles with addiction, isolation, and emotional instability. Tevis uses chess as a metaphor for mastery and control, a framework readers can use to find success in their own lives. Beth uses the act of playing chess as a medium to gain autonomy over her life. The Queen's Gambit is an opening strategy in chess, with the core goal of gaining control over the center of the board, the most advantageous position. The novel shows how the mastery of chess cultivates focus, patience, and resilience, ultimately translating into Beth achieving command over her own narrative. This paper also considers *The Queen's Gambit* as Tevis's swan song. *The Queen's Gambit* is a literary rendering of Tevis's greatest desires -for freedom from alcohol, pills, and social isolation. Tevis infuses his life story within Beth's, allowing her to defeat and transcend the cyclical demons ever present in Tevis's life. The novel is a chance for the author to symbolically achieve the control and fulfillment that have eluded him from an early age, when he was routinely given Librium, an early benzodiazepine, at a convalescent center. Tevis's depiction of chess reveals his admiration for structure and foresight. Tevis closes his career with a message of self-mastery, demonstrating how discipline and dedication can transform suffering into autonomy and purpose.

Abstract Name: Comparison of Seismic Performance and Economic Feasibility of Steel Special Moment Resisting Frame Building Designed for Deterministic and Probabilistic Ground Motions in Salt Lake City, Utah

In predicting seismic hazard for an area, ground motions are scaled either according to probabilistic seismic hazard analysis (PSHA) or deterministic seismic hazard analysis (DSHA). PSHA accounts for the recurrence interval of earthquakes on individual faults, whereas DSHA accounts for the maximum earthquake produced by a fault, independent of time. Current design codes use PSHA-based design spectra as the basis for seismic design. However, the seismic hazard in Salt Lake City, Utah, is dominated by the Wasatch Fault, which has long periods between events with the ability to produce magnitude M7.1 earthquakes. Due to this lower activity rate, PSHA results in lower seismic risk than DSHA, potentially leading to unconservative designs. In other words, buildings designed according to PSHA-based design spectra (i.e., code-based design) may have a higher risk of collapse under a deterministic scenario that is more likely to occur in Utah. This research compares the seismic performance and construction costs of designing special moment-resisting frames (SMRFs) for PSHA- and DSHA-based design spectra in Salt Lake City, Utah. A 4-story SMRF building archetype was designed individually based on both PSHA and DSHA design spectra. Finite element models of these archetypes were subjected to DSHA-based maximum considered earthquake (MCE)-scaled ground motions, and the results were processed to determine structural damage in terms of fragility functions. Upfront construction costs, including materials and erection, were estimated for each archetype to quantify the economic effects of designing according to DSHA compared with PSHA design. The results indicate that designing for a DSHA-based design spectra reduced the collapse risk while only incrementally increasing construction cost, providing an engineering solution to the potential seismic vulnerabilities on the Wasatch front.

Abstract Name: Finding High-Impact Undergraduate Experiences on your Campus: How to Find Opportunities Inside and Outside the Classroom

Access to high-impact research experiences can be a challenge for many undergraduate students interested in graduate school, especially those students at smaller campuses. For students who find themselves at large research institutions with faculty who have emphasis on applied clinical research this task may be made slightly easier, but nonetheless daunting. Given that research experience is one of the main factors for successful entry into graduate programs in clinical psychology and other professional medical schools, this challenge can become a potential barrier to entry for some (Keith-Spiegel & Wiederman, 2000; Privitera, 2014). As such, the purpose of the current oral presentation proposal would be to encourage networking opportunities and brainstorming ideas for undergraduates seeking high-impact research experiences on their campuses. The National Psi Chi Psychology Honor Society Faculty Advisor and Director of the McNair Undergraduate Research Program from Texas A&M University-Kingsville will lead an oral presentation which focuses on encouraging students how to find high-impact undergraduate research experiences on their own campuses. This will be useful for students that find themselves at big research institutions or even smaller liberal arts environments. Skills will be applicable and translatable in a range of academic settings and perspectives. The session will start with a brief introduction into the value of undergraduate research with recent studies about predictors of success to graduate school. We will then share personal narratives and success stories. Recent student research will be highlighted and summarized, showing attendees real-life examples of how to turn conference presentations into publications in undergraduate journals and other peer-reviewed spaces. This demonstrates how doable and manageable this task can be for you too! Attendees will learn practical ways to seek out and find opportunities and locally, regionally, and/or nationally for research engagement based on recent success stories and the research presented for discussion.

Abstract Name: Exploring sex differences in the relationship between CPR performance and SWM neurite density in an older Indian population

Despite growing interest in early markers of Alzheimer's disease (AD), the role of superficial white matter (SWM) in cognitive performance, especially apraxia, remains unclear. Apraxia, the ability to plan and execute movements, often emerges during AD progression and can be assessed using constructional praxis and recall (CPR) tests. Previous research indicates women perform better with praxis movements. Considering this, we hypothesize that the relationship between regional SWM neurite density and CPR scores differs by sex. We derived demographic, cognitive, and diffusion MRI (dMRI) data ($n = 221$) from Wave 2 of the Harmonized Diagnostic Assessment of Dementia for the Longitudinal Aging Study (LASI-DAD). SWM neurite density in the frontal, temporal, and limbic lobes was evaluated by neurite orientation dispersion and density imaging (NODDI) from T1-weighted and multi-shell dMRI. Linear regression analyses were conducted to examine the relationship between sex and WMN neurite density, controlling for age, education, scanning location, head motion during dMRI scan, and intracranial volume. We found that those with higher CPR scores had significantly higher ($T=2.26$, $P=0.02$) SWM neurite density in the frontal lobe. When examining sex interactions, women with higher CPR scores had significantly higher SWM neurite density in the frontal lobe

($T=2.93$, $P=0.004$) and temporal lobe ($T=2.76$, $P=0.006$) compared to men. Our findings suggest that women who had better CPR performance exhibited higher SWM neurite density than men, particularly in the frontal and temporal lobes. This relationship suggests that combining neuroimaging of white matter microstructure with cognitive assessments like CPR may enhance early detection of cognitive decline in women. Given known sex differences in praxis performance, such approaches may also support a need for sex-specific diagnostics.

Abstract Name: The association between hypertension and Alzheimer's disease among African Americans/Blacks in NHIS 2019-2023 dataset

African Americans/Blacks are at a greater risk of developing hypertension, or high blood pressure, when compared to other demographic groups. What may be less investigated is the link between hypertension, which on average develops earlier within a person's lifespan, and Alzheimer's disease (AD); therefore our research question focused on examining the association between hypertension and AD in African Americans/Blacks. We utilized the National Health Interview Survey (NHIS) data and extracted the variables hypertension, AD, age, sex, race, employment, income ratio, education, general health status, and marital status. This study consisted of 15,531 African American/Black participants. Of the participants, 210 (1.1%) had AD and 15,321 (98.9%) did not. Weighted data was used to run a descriptive statistics test, a chi-square test of independence, and a multivariate logistic regression. In the multivariate logistic regression, we found that African Americans/Blacks with hypertension had significantly greater odds (aOR: 1.79 [1.05-3.03], $p=0.03$) of having AD compared to those without hypertension. We found that those with poor/fair health status were found to have significantly higher odds (aOR: 7.39 [3.80-14.38], $p<0.001$) for AD compared to those with excellent health status. Not being employed was significantly related to higher odds (aOR: 11.76 [5.37-25.79], $p<0.001$) of AD when compared to those who are employed. Finally, age was significantly associated with AD ($p=0.04$). These results may suggest that African Americans/Blacks with hypertension have a 79% higher risk odds of AD. By understanding how hypertension affects the increased odds of AD in African Americans/Blacks, we may be better equipped to develop interventions and prevention programs.

Abstract Name: Methionine Restriction Promotes Immunogenic Cell Death in Triple Negative Breast Cancer

When cancer cells are treated with chemotherapy, they can die in a way that alerts and engages the immune system, known as an immunogenic cell death (ICD). The dying cancer cell can release certain molecules, including ATP, that immune cells recognize in order to initiate an anti-tumor response. However, not all chemotherapies cause the release of these immunogenic signals as they kill the cell. This study aims to determine whether a specific deprivation technique, called methionine restriction, promotes or initiates the

ICD process when used in conjunction with chemotherapy. Methionine is an amino acid that is integral to all protein synthesis. Thus, when methionine is restricted, we expect to see a larger concentration of immunogenic factors that could promote an immune response. Breast cancer cells were incubated first with either methionine-restricted media or normal media before the addition of the chemotherapy cisplatin or oxaliplatin. The cells were then examined for overall death and signals for immunogenic cell death. In examining cell death, there was a significant increase in the proportion of dead cells treated with cisplatin or oxaliplatin in conjunction with methionine restriction when compared to treatment with chemotherapy alone. Furthermore, there was a significant increase in ATP release in cells treated with methionine-restricted media and oxaliplatin together when compared to baseline ATP release. This research supports the idea that methionine restriction could go to promote an immunogenic cell death. Thus, methionine restriction could increase the potency of chemotherapy by engaging the immune system, which could ensure a higher success rate of the current breast cancer treatment options available to patients.

Abstract Name: Sick and Tired: Farlulu's Story in the Gambia

My research project explains how the exploitation and alienation of Liberated Africans led to their poor treatment in the Gambia from 1816 to 1843. More specifically, I explain how the facilities, religion, and childhood experiences of the Liberated Africans differed from the native African and European populations. This project builds directly off Kyle Prochnow's research on the Gambia, but goes deeper into the life histories of individuals instead of the larger themes Prochnow discusses. I also utilize several articles on Liberated Africans generally, namely by Richard Anderson and Érika Melek Delgado. While several authors write about the Liberated Africans in Freetown, Sierra Leone, I instead wanted to focus on the Liberated Africans in the Gambia since there is not much research on that niche. My methodology is based primarily on British parliamentary papers and the Registers of Liberated Africans. While both written by British officials, the parliamentary papers offer insight into the atmosphere of the areas the Liberated Africans were located in. The Registers of Liberated Africans provide the physical characteristics of every single Liberated African, which benefits my emphasis on individuals. Within my paper, I follow the story of Farlulu, a Yoruba person enslaved in Ouidah, "liberated" in the British colony of Sierra Leone, and disposed to the Gambia where he faced mistreatment and coerced labor, much like his prior enslavement. It is no secret that Liberated Africans still faced conditions like slavery, but my project focuses on the ones experiencing that mistreatment rather than the British and other Europeans who caused it.

Abstract Name: Plant Growth Promoting Rhizobacteria from Native Plants promote growth and induce drought Tolerance in Arabidopsis

Environmental stresses negatively impact crop production, and the increasing demand for food has led to the overuse of chemical fertilizers, which in turn harm soil health. Our lab's goal is to develop sustainable agricultural methods that increase crop production under varying environmental conditions. To achieve this, we are exploring the microbiome of native plants, such as *Ceanothus velutinus* (snowbrush ceanothus), to harness plant growth-promoting rhizobacteria (PGPR) for the development of biofertilizers. In this study, we screened previously isolated PGPRs from *C. velutinus* plant to evaluate their ability to enhance growth and improve drought tolerance in the model plant, *Arabidopsis thaliana* (thale cress). Each PGPR was cultured to an OD600 of 1.0, and 5 mL of it was applied to the roots of *Arabidopsis* seedlings three times with a week's interval in between. A total of six replicates (one plant per pot) were used for each treatment. The plants were grown for two weeks following the third treatment. After approximately six weeks of germination, the plants were harvested for both fresh and dry biomass measurements. The rosette diameter, number of leaves, and leaf surface area were also recorded. For the drought assay, the six-week-old plants were subjected to drought stress by withholding water for five days or until the control (non-treated) plants either died or wilted permanently. The plants were then rewatered for nine days, and the survival rates were subsequently assessed. We screened 13 notable PGPR strains for their effects on growth promotion, of which the five demonstrated a significant increase in plant shoot biomass. Additionally, of the eight isolates screened for drought tolerance, three showed a positive effect. The remaining isolates are being screened. Once screened in *Arabidopsis*, the positive isolates will be tested on various crops, including watermelon, tomatoes, maize, and wheat in both greenhouse and field conditions.

Abstract Name: Isolation and Characterization of Prokaryotic Riboflavin Kinases

Antibiotic resistance is a growing concern for human health that can be addressed through the discovery of new molecules designed to specifically target resistant bacteria by disrupting bacterial cellular processes. Riboflavin kinases (RFKs) synthesize the coenzymes flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD), which are required in life-sustaining cellular reactions that regulate cellular signaling, development, and defense against harmful reactive oxygen species across all life forms. Due to their prevalence and the specific structural differences between prokaryotic and eukaryotic isoforms, RFKs in prokaryotes are a potential target for the development of new antibiotics, as these differences can be exploited to create molecules that inhibit RFK activity in prokaryotes. Using various prokaryotic and eukaryotic RFKs, we have begun studies to investigate their differences using bioinformatics and laboratory methods. A sequence alignment was performed on the RFKs of various species using BLAST, Clustal, and ExPasy, and regions of high similarity and variance were identified for the active site amino acids. The RFKs were grown and purified using His-tag affinity chromatography, a technique that relies on the specific binding of the histidine tag to beads of a column. Thin layer chromatography (TLC) was used as a qualitative measure of RFK enzymatic activity, as the riboflavin substrate can be separated from the reaction intermediate (FMN) and the product (FAD) by differences in interactions with the solvent phase or TLC plate. As initial assays showed minimal separation, changes were made to the solvent system with butanol:acetic acid:water (40:10:50) v/v demonstrating the best separation. SDS-PAGE was utilized to determine the overexpression of various RFK prokaryotic samples and verify purification, as this technique separates proteins based on size differences. Ongoing work will examine observed differences in prokaryotic RFKs and explore various experimental conditions to optimize enzymatic activity.

Abstract Name: Bioprinted Scaffolds for Investigating Fibroblast Alignment and ECM Remodeling

Fibroblasts play a vital role in tissue repair, ECM remodeling, and maintaining structural integrity in human tissues. However, their behavior in engineered 3D microenvironments remains poorly understood. Traditional 2D cultures fail to capture the complex cell–cell and cell–matrix interactions that govern fibroblast alignment, migration, and proliferation in vivo. To address this gap, this project uses bioprinted scaffolds that mimic native ECM structures and provide a platform for studying fibroblast behavior in controlled microenvironments. The project focuses on varying scaffold channel properties—such as width, depth, and geometry—to investigate how physical cues influence fibroblast organization and collective migration. A biodegradable gelatin-based ECM material will be used to ensure biocompatibility and long-term culture stability while maintaining uniform surface morphology. By adjusting these geometric parameters, we aim to replicate physiologically relevant environments that guide fibroblast alignment and matrix remodeling, as observed in wound healing or tissue regeneration. This work seeks to overcome limitations in current bioengineering approaches that often fail to achieve consistent 3D cell organization and mechanical integrity. Through systematic comparison of scaffold designs, we expect to identify how fibroblasts respond to spatial confinement, stiffness variations, and surface topology. The resulting platform will enable the visualization and quantification of fibroblast dynamics, providing new insight into the role of physical cues in ECM synthesis and tissue architecture. Ultimately, these customizable scaffolds could serve as valuable models for studying fibrosis, wound repair, and soft tissue regeneration.

Abstract Name: Ancient Echoes - An Examination of Female Sexuality and Desire in Religion and Art within the Time Periods of Ancient Mesopotamia and Archaic Greece

Across a multitude of ancient cultures, female sexuality and desire have been expressed and documented, and yet remain quiet in the larger noise of historical scholarship. Female sexuality and the depiction of sexual desire and pleasure are intrinsically tied to the concepts of both religion and art; their importance to the creation of a collective cultural memory impossible to overstate. Religion, an area of focus within this essay with specific regard to Ancient Mesopotamia, provides a way to keep ancient women firmly situated within their culture, not separating them from their cultural context and the way in which they interacted with their society. Art, particularly the poetry and pottery examined in reference to Archaic Greece, is analysed in relation to religion through Sappho's works, while also being examined for cultural contexts in which religion is not explicitly referenced, with women existing in sexual contexts both independently and in conjunction with men. This essay also explores not solely the sexual expression of desire, but the romantic experiences of women towards objects of affection, both male and female. Through poetry, hymns, art, and religious practices, we can critically consider the powerful evidence that challenges the assumption that female desire and agency were wholly suppressed or invisible in ancient societies, and how even in patriarchal cultures, the

voices and experiences of women found their way into cultural memory, challenging norms and consequently enriching the modern understanding of the ancient world.

Abstract Name: Uncovering the Protective Mechanism of FAAH Inhibition in Cisplatin-Induced Nephrotoxicity

Cisplatin is a first-line potent chemotherapy drug used to treat a wide range of solid tumors. However, its clinical impact is limited by kidney injury at doses required for effective treatment. This nephrotoxicity affects quality of life and may require dose reduction or discontinuation of cisplatin therapy. Our recent research suggests that inhibiting fatty acid amide hydrolase (FAAH), the primary enzyme that degrades the signaling lipid anandamide (AEA) into arachidonic acid (AA), reduces cisplatin-induced renal cellular damage, but the mechanisms responsible for this protective effect remain unclear. This project seeks to determine how FAAH inhibition reduces cisplatin-related injury in kidney cells. Human kidney proximal tubular cells (HK-2) were treated with cisplatin, a selective FAAH inhibitor (PF-04457845), and/or drugs that block or activate specific endocannabinoid pathways to identify how FAAH inhibition alters cellular responses. Cell survival was measured using CCK-8 assays. Initial results showed that PF protected against cisplatin-induced cell death, and antagonists of AEA receptors did not affect this protection. However, protection was reversed using LM1413, a substrate-selective inhibitor to block AEA-COX2 but not AA-COX2, to inhibit cyclooxygenase (COX)-2, an alternative enzyme that converts AEA into prostamides. These initial findings indicate that protection by FAAH inhibition may occur through activation of the AEA-COX2 pathway independent of AEA receptors. We will use Western blotting and immunocytochemistry to measure changes in proteins related to stress and cell death to further compare cell viability and protein expression patterns across treatment groups, clarifying which pathways are altered when FAAH is inhibited in the presence of cisplatin. We expect to conclude whether FAAH inhibition protects kidney cells through receptor-related signaling, lipid-mediated pathways, or both. Understanding these mechanisms may lead to strategies that preserve kidney function during treatment and offer broader insights into preventing drug-induced nephrotoxicity.

Abstract Name: BrAInpower or ConstrAInt: The Importance of Human-Made Art and its Impact on Life in a Growing AI World

The spread of artificial intelligence (AI) in everyday life has caused a surge of uncertainty when determining what is human and what is not, especially in the realm of art. From this uncertainty, I decided to find out if AI artwork makes people react differently than art made by humans. This was determined by looking at scientific studies as well as the philosophical connection between humans and art. Previous research has looked at either the philosophical perspective or the scientific perspective, never both perspectives at the same time. It is by applying multiple scientific studies (KAUST and BGSU) and entropy scores (Khan and Kim) to

philosophers from the 19th and 20th centuries (Hegel and Langer) that demonstrates the positive impact on emotions and brain activity created by human-made art. AI art, while found to create emotion, was less influential on the individual than human made artwork. By conducting this study, our findings have shown that the numerous scientific experiments and research models line up with the ideas of the philosophers with regards to their opinions on art expressing a sense of freedom. This study demonstrates the importance of human made art in a rapidly growing AI world, with support from both science and philosophy.

Abstract Name: A Benziiodoxathiole-Derived Hypervalent Iodine Polymer as a Versatile and Sustainable Oxidant

We report the development of a novel polymer-supported hypervalent iodine reagent incorporating the 1H-1-hydroxy-1,2,3-benziiodoxathiole 3,3-dioxide moiety. The synthesis begins with the transformation of commercially available 2-amino-5-nitrobenzenesulfonic acid into 2-iodo-5-nitrobenzenesulfonic acid via a classical diazotization–iodination sequence. Subsequent reduction of the nitro group using tin in aqueous HCl affords 2-iodo-5-aminobenzenesulfonic acid, which is then covalently attached to a styrene–maleic anhydride copolymer under reflux in acetic anhydride with sodium acetate as a catalyst. Oxidation of iodine to the hypervalent state is achieved by treatment with aqueous Oxone® under acidic conditions at room temperature. The resulting polymeric reagent was evaluated in a series of oxidative transformations, including the rearrangement of arylalkanones, generation and nucleophilic addition to polymer-bound alkynyliodonium species, and oxidation of phenols to quinones. Finally, we propose potential applications of this recyclable hypervalent iodine polymer in microfluidic “lab-on-a-chip” devices as a sustainable oxidant platform.

Abstract Name: Russian Designer Aleksandr Rodchenko’s Impact on Modern Design

This paper strives to explore the impact of Russian designer Aleksandr Rodchenko on design both in the past and its transition to modern day design techniques. This paper will go over the history of Russian design, specifically during the era of *faktura* and how it evolved into constructivist principles. It will identify the key characteristics of these design eras and explore why this era was influential in Russian design history. The paper will further explore these design eras by looking at and analyzing Rodchenko’s work, analyzing some of his most popular pieces. It will examine Rodchenko’s background as a designer and the different experiences that helped him create his own style of design that soon became very influential. It will also include the different materials and mediums he used to create visually stunning pieces. The main goal of this research paper is to explain in depth how Aleksandr Rodchenko influenced design.

Abstract Name: Innovation, Stagnation, and Risk: Analyzing the U.S. Navy's Readiness for Future Conflict

This research analyzes the evolution of U.S. naval capability from the conclusion of World War II (WWII) to the contemporary era, investigating how alternating cycles of technological innovation and institutional stagnation have profoundly shaped the current fleet's operational readiness and strategic posture. The study addresses the research question: How have U.S. naval technological, doctrinal, and logistical innovations during the Cold War, and the subsequent decline in innovation after 1991, combined to shape the strengths and vulnerabilities of today's fleet? Drawing on historical process-tracing and analytical theories of military innovation, the analysis identifies two distinct phases. The Cold War era (1945–1991) is characterized by threat-driven, transformative innovation, institutionalizing doctrines like peacetime forward deployment and pioneering technologies such as nuclear propulsion and robust anti-submarine warfare (ASW), culminating in the expansive 600-ship Navy build-up. This period established the technological and doctrinal foundation for enduring global maritime supremacy. Conversely, the Post-Cold War era (1991–Present) witnessed systemic stagnation. The absence of a peer competitor following the collapse of the Soviet Union initiated a "Peace Dividend" that resulted in deep budgetary cuts, significant fleet reductions, deferred maintenance, and a cultural shift toward administrative efficiency. The subsequent two decades of the Global War on Terror further focused naval assets on expeditionary support missions, exacerbating an aging fleet and creating chronic readiness and maintenance backlogs. The paper concludes that while the legacy of Cold War innovation provides the U.S. Navy with unparalleled strategic strengths, the sustained post-1991 retrenchment has created critical vulnerabilities, including an atrophied shipbuilding base and insufficient capacity to meet the demands of great-power competition. Sustaining maritime dominance now requires an urgent, systemic revival of innovation and sustained investment to overcome institutional inertia and match the rapid modernization efforts of near-peer adversaries.

Abstract Name: Shoulder Strength Imbalances in Division III Collegiate Athletes

In the intense world of college athletics, shoulder stability plays a critical role in injury prevention and overall performance. Division III athletes, particularly those specializing in sports requiring significant upper body engagement, are at high risk for developing shoulder mobility deficits and muscle imbalances. This can lead to increased injury risk as well as reduced functional and athletic performance. In this study, we set out to investigate the prevalence of shoulder muscle imbalances and deficits in non-standard overhead athletes. These athletes perform overhead arm movements differing from those in typical overhead sports. Because of this, their shoulder adaptations and muscle imbalances are distinct from typical overhead athletes, creating a gap in current knowledge, warranting further careful exploration. Using a handheld dynamometer and the Athletic Shoulder (ASH) with a force plate, we assessed bilateral shoulder strength across multiple planes in female Division III track and gymnastics athletes aged 19 to 22. Preliminary results demonstrate significant

dominant to non-dominant muscle imbalances in track athletes, which were not observed in gymnasts. These findings align with existing literature, noting increased imbalances in single-arm dominant athletes. However, gymnasts demonstrated an increase in strength in the overhead planes, consistent with previous literature. Heatmaps have helped to enable clear visualization of asymmetries across different planes, facilitating the identification of potential injury risks, while also supporting individualized rehabilitation protocols. This research highlights the importance of individual assessment protocols for Division III athletes, promoting targeted rehabilitation and injury prevention strategies, ultimately aiming to enhance shoulder health and athletic performance in underfunded athlete populations.

Abstract Name: Effect of Psilocybin on Perineuronal Nets in the Ventral Hippocampus

Psilocybin, a psychedelic compound found in ‘magic’ mushrooms, has shown promise in enhancing neuroplasticity and holds potential for treating neuropsychiatric disorders. Neuroplasticity, the brain’s ability to form and reorganize synaptic connections, is regulated in part by perineuronal nets (PNNs), which are specialized extracellular matrix structures that stabilize synapses and restrict plasticity in the adult brain, potentially hindering recovery from certain conditions. This study investigates how psilocybin impacts PNNs within the ventral hippocampus (VHPC), a region critical for memory and emotional processing. To test this, C57BL/6J mice were administered 1 mg/kg psilocybin intraperitoneally and were sacrificed 2.5 or 24 hours post-injection. In addition, we tested the effects of psilocybin in 5-HT2A knockout mice 2.5 hours after psilocybin. The VHPC was analyzed using Wisteria floribunda agglutinin (WFA) and an anti-PV antibody to identify PNNs and PV neurons. Density of PNNs and PV neurons and WFA staining intensity was quantified using Polygon AI. Our findings revealed psilocybin treatment resulted in a significant decrease in perineuronal net (PNN) and PV intensity in female mice 2.5 hours after psilocybin. While no significant changes were observed in the number of WFA or PV-positive cells, sex-dependent differences in WFA and PV intensity suggest that male and female brains may respond differently to psilocybin. There were no changes found in PNNs or PV neurons at 24 hours or in 5-HT2A knockout mice. These findings suggest that psilocybin causes a rapid decrease in PNN intensity in females that may be 5-HT2A receptor dependent. This may facilitate neuroplasticity, and highlights the importance of considering biological sex in understanding its mechanisms and therapeutic potential.

Abstract Name: Jumpstarting Q-Learning with Suboptimal Pathfinding: Faster, More Reliable Learning in Pacman

Model-free reinforcement learning (RL) often learns slowly from scratch. We study a simple, practical way to speed it up: warm-starting tabular Q-learning with trajectories from suboptimal search agents. Using the UC Berkeley Pacman environment, we compare a cold-start baseline (all Q-values initialized to zero) to two warm-start agents initialized from demonstrations produced by (i) Depth-First Search (DFS)—systematic but path-length-heavy—and (ii) ClosestDotSearch—a greedy, Manhattan-distance heuristic tailored to food collection. All agents share identical hyperparameters ($\alpha=0.2$, $\gamma=1.0$, $\epsilon=0.05$) and training budgets (1,000 episodes; 15 independent runs) and are evaluated on two canonical layouts: smallGrid (7×7, 4 pellets) for rapid learning dynamics and mediumClassic (19×10, 240 pellets) for longer-horizon, strategy-heavy play. States are matched exactly by (Pacman position, food-bitmask) so initialization only affects the decision contexts actually encountered during play. Warm-starting is implemented by seeding $Q_0(s,a)$ along demonstrated state–action pairs (positive prior on taken actions, mild penalty elsewhere). The DFS prior provides broad state-space coverage; the ClosestDotSearch prior provides goal-directed, locally sensible action hints. Across layouts, warm-start agents learn meaningful policies earlier, exhibiting (i) faster convergence by standard stopping criteria ($\max \Delta Q \leq 0.01$; $\|Q_{\text{new}} - Q_{\text{old}}\| \leq 0.1$), (ii) higher average game score during early and mid training, and (iii) higher win rates under identical exploration. These gains are most pronounced on mediumClassic, where sparse rewards and long horizons penalize uninformed exploration. Intellectual merit. The study isolates a low-overhead mechanism demonstration-based Q-initialization—that measurably improves sample efficiency in tabular RL without changing the learning rule, policy class, or exploration schedule. Broader impacts. When unsafe or expensive exploration is a concern (e.g., robotics, education games), leveraging even imperfect behaviors to bias the initial value landscape can reduce time-to-competence, compute cost, and negative outcomes while remaining simple enough for classroom reproducibility.

Abstract Name: Degradation of Azithromycin and Gamithromycin in Water Using UV and UV/H₂O₂ Advanced Oxidation Processes

Antibiotic contamination in wastewater is a significant environmental and public health concern due to its role in promoting antimicrobial resistance (AMR). Macrolide antibiotics, specifically azithromycin and gamithromycin, are widely used in animal agriculture and persist in aquatic environments because conventional wastewater treatment processes often fail to fully degrade them. This study evaluates the effectiveness of ultraviolet (UV) irradiation and UV/H₂O₂ advanced oxidation processes (AOPs) for the degradation of these macrolides in water. Batch experiments are conducted using a 254 nm UV reactor. To ensure experimental accuracy, ferric oxalate actinometry is performed to calibrate photon flux and adjust UV production rates over time. Degradation efficiency is evaluated under varying operational parameters, including pH, contact time, and oxidant concentration, with quantification via liquid chromatography–tandem mass spectrometry (LC–MS/MS). While UV photolysis alone is assessed, hydrogen peroxide (H₂O₂) is introduced as an oxidant to generate hydroxyl radicals ($\bullet\text{OH}$), which significantly enhance degradation rates. It is expected that the combined UV/H₂O₂ process will exhibit substantially higher macrolide degradation efficiency than UV treatment alone, with performance influenced by oxidant concentration and water matrix composition. Optimized conditions are examined in both deionized water and synthetic wastewater to assess treatment efficiency across controlled aqueous matrices. This research aims to support the development of scalable water treatment strategies to reduce antibiotic residues, limit the spread of AMR, and improve environmental and public health outcomes.

Abstract Name: Women on the Bench: Judicial Philosophies of Female Supreme Court Justices Across Ideological Lines through the Lens of the 14th Amendment

This study examines how the six women who have served on the United States Supreme Court have interpreted the Fourteenth Amendment, focusing on the Equal Protection and Due Process Clauses, to understand whether gender influences judicial philosophy. Through analysis of major opinions and dissents authored by Justices Sandra Day O'Connor, Ruth Bader Ginsburg, Sonia Sotomayor, Elena Kagan, Amy Coney Barrett, and Ketanji Brown Jackson, the study finds that their judicial reasoning aligns more strongly with ideological commitments than with gender. Conservative justices, such as O'Connor and Barrett, emphasize judicial restraint, originalism, and limited interpretations of substantive due process and equal protection. In contrast, liberal justices, like Ginsburg, Sotomayor, Kagan, and Jackson, advance a living constitutionalist approach that centers evolving standards of equality, lived experience, and substantive protections for marginalized groups. While gender shapes individual perspectives and sensitivity to issues of discrimination, the analysis shows that it does not produce a unified "women's voice" on the Court. Instead, the female justices collectively reveal that constitutional interpretation is driven primarily by interpretive philosophy, demonstrating that ideological diversity among women on the bench mirrors broader divisions in the broader landscape of legal theory in the United States.

Abstract Name: Land and Sovereignty: How Conflicting Perceptions of Land Influenced Cherokee/Settler Relationships and Actions in the Early 19th Century.

This paper uses land as a framework to unpack U.S. settler/Cherokee relationships and actions in the early 19th century. Land sat at the center of their motivations: for settlers, economic extraction of natural resources, and for Cherokee people, protecting their sovereignty, homes, and identities. Research for this paper is grounded in correspondence between U.S. and Cherokee individuals that demonstrate a contest over the meaning of land, arguing either protect it or possess it. The Jeffersonian Indian policy ethos, exemplified by the civilization program, was embraced by Cherokees who adopted beneficial European innovations and ideas while rejecting ones they found unappealing. The standards for Native Americans to become civilized—namely becoming commodity agriculturalists, capitalists, and Christians—were adopted by Cherokee society to such a degree that U.S. officials had trouble justifying removal on the basis of civility. Following the Creek War and the introduction of a less sympathetic Jacksonian democracy, Cherokee governance centralized with a focus on protecting territory. Cherokee leaders understood that land was central to the U.S. settler colonial project, and that protecting land meant protecting their sovereignty, therefore themselves, their families, and their identities. For instance, diplomatic correspondence demonstrates how the meaning of land was contested: for Cherokee people like Principal Chief Pathkiller, land represented a web of reciprocal relationships which informed identity, whereas for settlers like Tennessee governor Joseph McMinn, land represented divinely ordained economic opportunity. Like many other Native American ontologies, Cherokee people understand their relationships to land and the nonhuman world as being grounded in reciprocity—humans are not superior and removed from the nonhuman environment, as is so often encouraged by

colonialism. Thus, with a focus on how both settlers and Cherokee people understood land, this paper reveals a more intricate analysis of their relationship and actions in the early 19th century.

Abstract Name: Mapping Student Pathways: Mixed-Methods Insights into Student Navigation of UT Austin Degree Plans

This study expands on previous inquiry by analyzing how measures of curricular complexity correspond to student experiences, and by identifying structural influences on student progression. The central research question is: How do quantitative indicators of curricular complexity correspond to individual student experiences of degree planning, course selection, and progression toward graduation? Curricular Analytics (CA), developed by the Association for Undergraduate Education at Research Universities, offers a quantitative approach to understanding curriculum structure through mapping complexity and centrality within degree programs. Using a mixed methods approach, the research question was addressed by generating curriculum maps and complexity-related metrics for the 141 undergraduate degree programs at The University of Texas at Austin. A “flexibility score” measuring the percentage of a degree program’s hours in which the student has course-selection agency was calculated for each degree program. The relationship between complexity and flexibility across degree plans was then analyzed, focusing on patterns by college-school-unit (CSU) and degree type. Initial results indicate that degree programs with high complexity tend to exhibit low flexibility, demonstrating that strictly sequenced, prerequisite-heavy curricula limit student agency in course selection. Complementing this quantitative work, 20 qualitative semi-structured interviews with UT Austin students were thematically analyzed to better understand their approaches to degree navigation, resource use, and factors outside the curriculum. Preliminary findings suggest that while faculty and staff may recognize curriculum bottlenecks, a gap exists in understanding between institutional perceptions of curriculum design and barriers students encounter. Interview data highlights that students frequently diverge from suggested pathways due to course unavailability, scheduling constraints, or setbacks in high-centrality courses. Many students therefore rely on informal tools rather than official institutional resources to stay on track. Together, these findings suggest that structural features of curriculum, not just individual student behavior, substantially influence time-to-degree completion.

Abstract Name: Lost in Translation: Neural and Visual Responses to Foreign Packaging

The present study investigates how consumers identify products when confronted with packaging written in unfamiliar languages. As global cultural and linguistic diversity increases, individuals encounter products more frequently whose textual information they cannot decode, raising questions about how consumers

extract meaning from packaging in the absence of linguistic comprehension. This research integrates eye-tracking data with survey responses to examine whether participants can accurately infer product identity when viewing items labeled in four non-Latin script or Germanic-based languages, and which visual cues guide their judgments. Participants viewed images of products paired with nutritional or informational labels, presented in one of four languages, and were subsequently asked to identify the product. Analysis of fixation patterns and self-reported strategies revealed that participants relied predominantly on the shape and structural features of product packaging when forming inferences. Survey responses further demonstrated that participants identified products more accurately when packaging conformed to familiar visual schemas, whereas products featuring unfamiliar or ambiguous packaging were frequently misidentified. These findings suggest that packaging shape functions as a primary heuristic in cross-linguistic product recognition, particularly when textual information is inaccessible. The study highlights the strategic importance of packaging design for marketers targeting increasingly diverse and international consumer segments. Products relying on non-distinctive or unconventional packaging are more likely to be overlooked or misinterpreted in multicultural retail environments. Consequently, attention to universally recognizable packaging features may enhance product accessibility, support market expansion, and reduce consumer confusion in a globalized marketplace.

Abstract Name: "Beyond Problem Solving: Harnessing AI for Mathematical Reasoning and Communication"

Large language models (LLMs) such as MathGPT represent a transformative development in mathematics education, offering novel modes of interaction between humans and computational systems. Beyond automated problem solving, LLMs provide a platform for mathematical discourse, enabling dynamic exploration of multiple solution pathways, natural language feedback, and adaptive explanations. This presentation examines the pedagogical potential of LLMs in fostering conceptual understanding, metacognitive reflection, and mathematical communication. At the same time, it addresses the technical and educational challenges inherent in deploying these systems, including issues of reliability, alignment with disciplinary standards, and the design of scaffolds that promote productive struggle rather than overreliance. The session will consider research-based frameworks for integrating LLMs into mathematics learning environments and outline directions for future investigation at the intersection of AI, cognitive science, and mathematics education.

Abstract Name: How do Invasive Plant Density and Herbicide Application Rates Influence the Success of Riparian Buffer Restoration Over a Two-year Period?

Riparian buffers are one of the most effective strategies for improving stream water quality, stabilizing streambanks, and supporting wildlife. Yet many restored sites experience inconsistent maintenance and invasive plant species succession, leading to reduced native vegetation diversity and loss of function over time. Herbicide is a common management tool for restored riparian buffer maintenance. This study examines how invasive plant populations respond to herbicide application rates and methods — which influence the success of riparian buffer restoration. We collected data on different types of herbicide treatments and compared target invasive plant relative density over a two-year period (2024-2025) across 16 restoration sites in Lycoming, Snyder, and Union Counties, Pennsylvania. Our results indicate herbicide management helps mitigate some invasive plant populations. For example, callery pear (*Pyrus calleryana*) populations declined from 0.05 occupancy rate across all sites from 2024 to <0.01 in 2025 ($p = 0.01698$, $R^2 = 0.1581$). However, this trend is not the case for all species, such as reed canary grass (*Phalaris arundinacea*; $p = 0.0877$, $R^2 = 0.066$). These findings suggest moderate herbicide use paired with consistent monitoring may gradually improve restoration outcomes by limiting invasive plant densities and promoting native plant biodiversity restoration. Next steps involve returning to sites that overlap across two years to measure diameter breast height of tree species to determine which specific tree species are showing significant growth to quantify riparian buffer success. Across three sites so far, we found that DBH is marginally significant over sites that use tree shelters over those that do not ($p = 0.0546$), suggesting that tree shelters may enhance early growth. In addition, we plan to compare tree DBH across all sites to invasive densities to test correlations, providing insight into whether invasive suppression is directly associated with native tree growth and overall buffer recovery.

Abstract Name: Prediction, Synthesis, and Experimental Validation of Magnetic Order and Dimensionality in Cerium-Based Compounds Guided by Structural Characteristics, Tri-critical Exponents, and Unsupervised Machine Learning

Cerium (Ce), the most abundant and chemically versatile lanthanide [3], offers significant potential for addressing critical shortages in high-performance magnetic materials, particularly by enabling the discovery of novel compounds suitable for gap magnets [1, 2]. Predicting magnetic order and dimensionality in cerium-based compounds is essential due to their complex magnetic and electronic characteristics. In this study, we integrate structural descriptors (lattice symmetry, valency, bond lengths, coordination environments) and tri-critical exponents within an Ising Model-based framework to systematically explore and predict magnetic phenomena. Utilizing the Ising Model allows accurate simulation of spin interactions, thereby refining predictions of magnetic ordering and critical behavior. We further enhance predictive accuracy by coupling

unsupervised machine learning algorithms, specifically autoencoders trained on affinity-based features, with Monte Carlo simulations informed by the Ising Model. This innovative approach enables the automatic extraction of latent parameters crucial for determining magnetic phase boundaries and transitions, such as lattice-induced anisotropy and critical temperatures. Moreover, this method allows for scalable and generalized exploration beyond traditional models, providing deeper insights into phase behavior and the underlying physics of magnetic ordering. Selected cerium-based compounds predicted via this integrated computational framework are subsequently synthesized and experimentally validated. This synergistic approach establishes a continuous feedback loop, refining computational models and enhancing predictive fidelity. By extending existing methods through advanced feature construction and unsupervised learning techniques, we provide a powerful, scalable methodology for identifying new magnetic materials. Ultimately, this study deepens fundamental understanding of magnetism in cerium-based compounds and creates a robust platform applicable to exploring and engineering next-generation magnetic materials within the broader lanthanide [3] and actinide [4] families.

Abstract Name: The Extent of Capabilities of Autoregressive and LightGBM Models in Forecasting Air Quality

Air pollution remains one of the leading threats to public health, with particulate matter and gaseous pollutants causing millions of premature deaths every year. In cities such as New Delhi, India, pollutant concentrations exhibit strong seasonal and temporal variability. This complicates efforts to issue timely public health warnings and prepare hospitals for pollution related cases. This study investigates which forecasting models can accurately predict seasonal Air Quality Index patterns using historical pollutant data. Inspiration had come from the paper “Air Quality Prediction using Machine Learning” by Rohit Kumar Singh and others. We had noticed some points of interest in their work on which we could improve upon by using better models and a wider data source. Some of these included the reading of seasonal trends with different models and the inclusion of meteorological data to more accurately predict pollutant fluctuations. Hourly pollution concentration data for major pollutants were first converted into monthly AQI indices to create a consistent time series for modeling. Meteorological variables such as temperature, relative humidity, wind speed, and rainfall were incorporated as external predictors due to their strong influence on pollutant formation and concentration. Two modeling approaches were developed: a Seasonal AutoRegressive Integrated Moving Average with Exogenous Variables (SARIMAX) model and a tree-based LightGBM model. The SARIMAX model was tuned through an expanded grid search using Akaike Information Criterion minimization and validated on out-of-sample data. In parallel, the LightGBM model employed lag features, rolling statistics, and utilized meteorological interactions. Results showed that SARIMAX achieved lower RMSE for PM_{2.5}, O₃, PM₁₀, and NO₂, indicating strong seasonal structure in these pollutants. LightGBM performed best for SO₂ and CO₂, reflecting greater nonlinear meteorological influence. Overall, both models captured key pollutant trends, with SARIMAX performing best with seasonal structures and LightGBM in exogenous-driven variability.

Abstract Name: Implications for Indirect ECS Modulation: CBD and CBG Inhibition of SCP-2 by Cannabinoids: A Fluorescent Lipid Assay for Anxiolytic Drug Development

Every year globally an estimated 301 million people suffer from anxiety without safe dependable medications. Recent research suggests that neurological mechanisms may offer alternative therapies. The endocannabinoid system (ECS), a signaling system modulating neurotransmitter activity, is supported by sterol carrier protein-2 (SCP-2), a ECS lipid-binding protein found in synaptic spaces that facilitate movement and action between pre- and post-synaptic neurons. Inhibiting SCP2's binding function in mouse models has shown evidence of reducing anxiety. Direct modulation of the ECS by the psychoactive ingredient in *Cannabis sativa*, reduces anxiety but leads to problematic behavioral side effects. Alternatively, nonpsychoactive compounds within *Cannabis*, Cannabinol (CBD) and Cannabigerol (CBG), are also anxiolytic, despite the lack of understanding in the mechanism. In previous studies, we observed that both CBD and CBG can interact with SCP-2, prohibiting its lipid binding which indirectly may affect the ECS. The goal of this study is to examine the effects of CBD and CBG on lipid trafficking across membranes, in SCP-2 cellular models. Human embryonic kidney cells (HEK) that express SCP-2 (HEK-SCP-2 cells) were used and incubated with fluorescent lipids (nitrobenzoxadiazole derivatives, NBDS) in the presence and absence of inhibitors (CBD, CBG and known inhibitor JWii2a). The cells were imaged using a fluorescent microscope and assessed via ImageJ. We compared fluorescence intensity between control cells and cells treated with an inhibitor. We expect to observe decreased fluorescence within cells with inhibitors compared to control cells. In future studies, custom compounds can be tested and analyzed using this cellular assay to make a new wave of anti-anxiety medications. These medications could be more effective than what is available on the market today. These improved pharmacological tools could reduce the effects of anxiety, leading to less isolation, depression, improved relationships, and improvement in individuals' ability to work and study.

Abstract Name: From Bedtime to Bacteria: A Sleep Extension Pilot Study Revealing Gut-Linked Pathways

While the gut contains trillions of bacteria that influence the immune, nervous, and endocrine systems, its implications in health interventions and wellness are often underappreciated. Lifestyle factors, including sleep duration and quality, influence gut microbiome composition and are linked to adverse health outcomes. While sleep extension is known to benefit health, emerging evidence suggests the gut microbiome and inflammatory pathways may help clarify these underlying mechanisms. This pilot study examined the effects of a two-week sleep extension on the gut microbiome composition in healthy adult females as part of a larger investigation of sleep, stress, and systemic inflammation. Participants completed two weeks of baseline monitoring followed by two weeks of extended sleep, during which objective time in bed and total sleep duration significantly increased. Pre- and post-intervention assessments included stool sample collection for microbiome profiling. Although gut microbiome diversity remained unchanged, there was a significant increase of *Peptostreptococcus*, a genus producing short-chain fatty acids and the tryptophan metabolite indoleacrylic acid (IA), both of which support gut barrier integrity and modulate inflammation. These findings suggest that short-term sleep extension influences specific microbial taxa, highlighting the gut's role in mediating sleep-related health outcomes and its potential for guiding future gut-targeted interventions.

Abstract Name: Utilizing the Abilities of Ultrasonic Sensors to Detect Objects Around Heavy Vehicles for Safety Purposes.

My project is an ultrasonic sensor designed to add safety measures to large vehicles by scanning the environment surrounding the vehicle for objects. The societal benefit of this product is the reduction in accidents surrounding heavy vehicles and an increase in environmental awareness in heavy vehicles as large vehicles often have trouble checking blind spots due to not having clear lines of visibility to certain areas of their environment. These sensors will give heavy vehicles a better spatial awareness of the environment closely surrounding it, which can be used to make decisions and warn drivers and operators of potential risks. The technical need for ultrasonic sensors compared to other leading sensors for the purpose of environmental analysis has to do with the high reliability at close range and the low cost of ultrasonic sensors. Ultrasonic sensors have strengths in economical cost and short-range accuracy. Many current vehicles safety systems rely on radar, LiDAR, cameras, or a combination of these three. These devices have relevant weaknesses that an ultrasonic sensor would better account for. My hypothesis is that these ultrasonic sensors will perform better during adverse conditions at close range object detection. This would make them a good sensor for close range environmental scanning for the safety of heavy vehicles. The methodology that I will use to test my hypothesis and gather data to support my claim will be a prototype model of an ultrasonic sensor that I will test for its strengths and weaknesses compared to the other sensor types under certain conditions. The expected results are that the ultrasonic sensors will outperform LiDAR at close range in adverse conditions. This will be quantified by the detection miss rate and distance measurement error.

Abstract Name: Finding the Perfect Microbial Partner for Peanuts

This research was conducted to screen rhizobia from long-term peanut stands in Georgia, aiming to identify isolates with potentially superior nitrogen-fixing abilities. The goal of this research is to identify superior strains that can be commercialized to enhance peanut yields and reduce the need for synthetic fertilizers, which can be harmful to the environment. The Random Complete Block Design (RCBD) was used in this experiment to minimize variation and reduce biases in results. 8 replicates of 10 treatments (8 new isolates + 1 commercial isolate + negative control), arranged in a randomized complete block design. Whole peanuts were inoculated with 1mL of 0.1 OD of rhizobia strain or 1mL PBS (negative control). Soil mixture, 4 parts sand, 2 parts field soil, 2 parts vermiculite (4:2:2). Duration of experiments: 62 days. Starting at week eight, 45 microliters of Hoss Micronutrients for each unit weekly. Plants were cut at the soil level, and the weight was measured above and below ground. Roots and shoots were dried and weighed to obtain dry weight. Based on the data analysis, the ANOVA and Turkey Test results, there were no statistically significant differences between any of the three groups. A P-value of 0.086 was obtained, indicating that further experiments with larger sample sizes are necessary to compare and lower the P-value, thereby demonstrating differences in plant sizes due to the presence of their rhizobia. Three of the negative controls were removed for nodule presence. Three samples were removed for irregular growth.

Abstract Name: Assessing Psychological and Physical Safety of Transgender Students at Virginia Tech: A Mixed Methods Approach

A place of psychological safety refers to a community or an environmental setting wherein one feels included and able to ask questions and contribute without fear of negative consequences. A physically safe environment is free from violence and threats of violence. Therefore, psychological safety is essential for a person's wellbeing. Previous studies of transgender college students discovered alarming levels of transphobic harassment and discrimination— conditions that create psychologically and physically unsafe environments wherein students are unable to flourish. Our research question: Do transgender students at Virginia Tech feel safe, and if not, what dimensions of their safety concern them most? Moreover, what can the Administration do to be more supportive? The present study applied a 60-question self-report survey to assess the perceived psychological and physical safety of 31 transgender students at Virginia Tech. A total of 57 cisgender students took a similar questionnaire for comparison. The results provided insight regarding where, at both a policy and community level, the University could better serve its transgender student body. As of Fall 2025, 19 survey sections displayed statistically significant differences in responses between trans and cis students, with an additional six survey sections displaying marginal significance. Of the transgender respondents, 84.6% had been in a situation on campus where they felt threatened because of their gender presentation, compared to only 17.9% of the cisgender respondents. Transgender participants felt less support by the Virginia Tech Administration, and they were more concerned about the negative behaviors of faculty, staff, and other students than were the cisgender students. This semester we continued qualitative one-on-one interviews with transgender respondents and analyzed seven completed interviews in order to gather more in-depth responses and categorize the survey results. Preliminary analysis revealed trans participants felt ignored, and that their concerns were not adequately understood nor addressed by the Administration.

Abstract Name: Investigation of the Effect of Relationship Status and Amount of Screenshot

This research aims to study screenshot usage between singles and people in romantic relationships. There are numerous challenges introduced by increased technology use in relationships, such as decreased intimacy, distancing, lack of trust, and a sense of loss of dedication (Hertlein & Ancheta, 2014). No matter the app being used, technology usage has grown exponentially in the past decade. It was hypothesized that those in a relationship will have higher screenshot averages than those who are single. Participants began by rating how frequently they engage in the following phone related behaviors: "I keep my phone on me at all times," "I use my phone during leisure time," "I pull my phone out when it rings or buzzes when I am engaging in conversation with someone," and "I keep my phone where I can see it when I am with company." They were also asked to report their weekly screenshot in minutes by looking it up in their phone's screenshot tracking

app. Results from an independent-samples t-test showed that there was no effect of relationship status on screentime ($p = .56$); however, singles were more likely to keep their phone on them at all times ($p = .03$). Additional correlational analyses showed that age was negatively associated with all phone related behaviors ($ps \leq .04$), and independent samples t-tests suggested trends that males were more likely to keep their phone on them at all times and reported higher screentime usage than females ($ps \leq .05$). These findings suggest that relationship status is not a strong predictor of screentime usage compared to age. Future studies should further investigate factors that lead to more screentime usage as these results could inform the development of interventions to reduce screentime and phone dependence.

Abstract Name: Assessing the Influence of Headphone Use on Gratitude Expression Following a Behavioral Prompt

Interpersonal gratitude—an expression of gratitude to another person—enhances the wellbeing of those who give and those who receive a “thank you.” The use of headphones has increased significantly and may reduce interpersonal conversations and expressions of gratitude. The first phase of this applied behavioral science (ABS) study found 30% of 6,123 dining-hall customers wore headphones, and customers not wearing headphones (55% of 6,116 customers) were substantially more likely to express gratitude than customers who were wearing one headphone (8% of 6,116 customers) or two headphones (13% of 6,116 customers). This naturalistic ABS study was designed to determine the impact of a behavioral prompt designed to decrease headphone use, thereby increasing expressions of gratitude. At two university dining facilities, trained research students systematically observed and recorded whether customers thanked their cashier and noted their headphone usage: none, one, or two headphones/earbuds. Similar to our previous findings, customers not wearing headphones were more likely to express gratitude (38% of 6,300 customers) than customers who were wearing one headphone (7% of 6,300 customers) or two headphones (12% of 6,300 customers). Unfortunately, the prompt was not successful at decreasing overall headphone use (32% of 6,300 customers) and did not increase expressions of gratitude.

Abstract Name: Effect of Leaf Wax on Feeding Preferences of *Pieris rapae* Caterpillars

The small white butterfly, *Pieris rapae*, is ubiquitous and feeds on plants in the Brassicaceae family. *Pieris rapae* caterpillars cause significant foliar damage in cruciferous crops, reducing yields and increasing pest-management costs. A previous study by Ueno et al. (2025) showed that cabbage leaf epicuticular wax deters female oviposition and larval feeding of *P. rapae*. They found that removing leaf surface wax (n-nonacosane) on cabbage significantly increased oviposition. This shows a strong role of physical leaf surface traits in

oviposition behavior, and underlines that leaf-type differences (wax content) may influence oviposition in this species. Studies have mainly focused on oviposition preferences in the *Pieris rapae* species. Our study expands on research on the feeding preferences of 4th-instar *P. rapae* caterpillars on collards (*Brassica oleracea*). We predicted that *P. rapae* caterpillars would consume more unwaxed leaves due to reduced surface barriers. Experiments were conducted with 10 replicates per trial, with one 4th-instar caterpillar per Petri dish containing one waxed and one unwaxed leaf disc. Wax was removed from leaves using cotton balls to create unwaxed samples. After 24 hours, leaf consumption was quantified using the LeafByte app, which measures total surface area consumed in percent. Control trials measured natural leaf shrinkage over 24 hours, averaging 0.01% for unwaxed leaves and 0.002% for waxed leaves. We found caterpillars consistently consumed more unwaxed leaves than waxed leaves. The average consumed across four trials was 6.34% for unwaxed leaves and 4.44% for waxed leaves. Our analysis confirmed a significant preference for unwaxed leaves ($p = 0.01$, T-test, two-tailed). These results support our hypothesis that wax reduces herbivory by *P. rapa*. Our study demonstrates the important role epicuticular wax plays as a plant defense mechanism in cruciferous crops, suggesting that maintaining or enhancing wax could help protect cruciferous crops on farms.

Abstract Name: Effect of pH on Transcription Efficiency in C-Rich DNA Constructs

Changes in pH can dysregulate transcription, which negatively impact overall gene expression. The promoter region, where transcription begins, often contains C-rich sequences that can fold into an i-motif, a stable secondary structure that forms under acidic conditions below pH 6.5. Low pH can also negatively impact the activity of RNA polymerase. As the result, it is important to understand how these factors influence transcription. We hypothesized that at acidic pH, changes in transcription are driven mainly by i-motif formation. Circular dichroism (CD), in vitro transcription assays, and single molecule Förster resonance energy transfer (smFRET) were used to study the dynamic folding of i-motifs in C-rich DNA sequences and their impact on transcription at different pHs. We confirm the formation of i-motifs at lower pHs (around 6.2-6.5) has a negative impact on the efficiency of transcription in-vitro, and the stability of i-motifs is dependent on sequence length, pH, temperature.

Abstract Name: Inhibitory Activities of Surface-Associated Bacteria from California and Florida Algae

Marine algal surface-associated bacteria (SAB) inhabit highly competitive and diverse marine environments, where they face various stressors, including high salinity, osmotic pressure, and UV radiation. In response,

these bacteria produce secondary metabolites that may function as chemical defenses, including potential antibiotics active against human pathogens. In this study, we isolated and evaluated SAB from marine algae collected on two U.S. coasts, comprising 332 California isolates and approximately 200 Florida isolates. We screened these isolates for antibacterial activity against four clinically prevalent pathogens—*Escherichia coli*, *Bacillus subtilis*, *Staphylococcus aureus*, and *Salmonella* sp.—using pour-over assays for on-plate inhibition, Kirby-Bauer disk diffusion for extract activity, and a single-dose broth assay for liquid-phase confirmation. The 15 active strains were scaled in A1 medium, their metabolites were captured with XAD-16 resin, and the determination of the minimum inhibitory concentrations following solvent partitioning yielded 3 active fractions. The 3 active ethyl acetate fractions were then analyzed by HPLC and LC-MS, and phylogenetic identification was performed using 16S rRNA gene sequencing and Sanger sequencing. Altogether, this workflow provides a systematic analysis of algal SAB antibacterial activity and establishes a pipeline for the discovery of new secondary metabolites.

Abstract Name: Forecasting Labor Market Inequality with Artificial Intelligence

Accurate unemployment forecasting is essential for economic planning and timely policy decisions. Traditional forecasting methods often rely on lagging macroeconomic indicators that fail to capture sudden changes in labor market conditions. Real-time digital behavioral data, such as job-related Google search activity, provides immediate signals of job-seeking behavior and labor market sentiment. This study develops a hybrid deep learning model that combines Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) networks to forecast the United States unemployment rate. The model integrates monthly unemployment rate, GDP growth, CPI growth, and seven job-related Google Trends queries. Data are scaled using MinMax normalization and evaluated with an 80/20 train-test split. Results show that the hybrid LSTM-GRU achieves lower prediction error compared to the standalone LSTM and GRU models, with an RMSE of 0.1438, MAE of 0.1111, and MSE of 0.0207. Although the models function as black-box neural networks without direct interpretability, the improvements in forecasting accuracy demonstrate the practical value of combining traditional economic indicators with real-time search data for short-term unemployment prediction.

Abstract Name: Validation of Transport and Golgi Organization 2 (TANGO2) Deficiency Models

TANGO2 Deficiency Disorder (TDD), first described in 2016, is a rare autosomal recessive disorder caused by pathogenic mutations in the Transport AND Golgi Organization 2 (TANGO2) gene. TDD tends to manifest in early childhood, leading to a wide array of clinical symptoms, including neurodevelopmental delay, gait incoordination, speech difficulties, and seizures. In addition, individuals are susceptible to life-threatening

acute metabolic and cardiac crises. Cardiac crises are defined by the development of ventricular arrhythmias, cardiomyopathy, or cardiac arrest during an acute metabolic crisis. Often, these ventricular arrhythmias are difficult to control and unresponsive to typical arrhythmic therapy, being the leading cause of death in these patients. This study aimed to establish the validity of TANGO2 deficiency models utilizing TANGO2 knockout (KO) mice and siRNA-treated AC16 human cardiomyocyte cells. Protein expression was quantified via Western blotting in ventricular, liver, kidney, and spleen tissues from both KO and wild-type mice. In parallel, RNA expression in these same tissues was assessed using quantitative PCR (qPCR). To extend this analysis, I also performed Western blotting on AC16 cells treated with siRNA, targeting TANGO2 exons 8 and 9, at varying concentrations. Across both systems, I observed either a complete absence or a significant reduction of TANGO2 expression at both the protein and RNA levels in experimental groups compared to controls. These findings confirm that the KO mouse model and siRNA-treated AC16 cells are valid models of TANGO2 Deficiency Disorder. Establishing these models provides a critical foundation for investigating the molecular mechanisms underlying TDD and supports future translational research aimed at therapeutic development.

Abstract Name: Clinical Outcome for Fish and Shellfish Oral Immunotherapy

Introduction: The prevalence of seafood allergy (fish and shellfish) is 1-2% worldwide. There are limited clinical reports on seafood oral immunotherapy (OIT). A major challenge for seafood OIT is the lack of a protein source to develop the treatment. This case report describes the clinical outcome of 5 patients with seafood allergy treated with codfish or shrimp OIT. **Methods:** Patients from our allergy practice with fish or shellfish allergy were confirmed with SPT, specific IgE, and oral challenge. Informed consent was obtained. Dehydrated shrimp or codfish powder was used to develop the shrimp or fish OIT. The initial OIT protein dose was 2.5mg for shrimp and 5mg for codfish. The patients would ingest 5mL solution of the protein daily with weekly dose escalation over a 4-month period, then transition to eating per weight of cooked 500mg shrimp or 1000mg codfish daily followed by weekly dose escalation over a 3-month period to reach age-appropriate serving size. **Results:** Five patients (3 fish and 2 shellfish allergy, 1 female, 4 males, 5-18yo, 10-25mm wheal, 2-35 kU/L specific IgE) completed the treatment. Two patients reached full-serving size and three were maintained at one shrimp or fish stick (~10g) due to dislike of taste. Common adverse reactions were transient oral pruritis (~75%), localized lip swelling (~50%), and abdominal pain (~40%). No anaphylaxis or systemic allergic reaction requiring antihistamine or epinephrine. **Conclusion:** It is possible to treat seafood allergy using dehydrated shrimp or fish powder for OIT. The taste is tolerable and adverse reactions are mild with appropriate dose-escalation protocols.

Abstract Name: The President and Media's Role in President Press Conferences

In this project I research how the media as its own institution carries the responsibility of holding the government accountable, but can also drive their own agenda by choosing how events are framed. The president on the other hand tends to consistently generate headlines as they work to set the government agenda, but rely on news coverage of speeches and statements, and the media's power to frame them. News conferences allow journalists to directly question the president on topics they want to cover, regardless of whether the issue is what the president wants to discuss. Presidential influence during press conferences occurs when they choose media outlets to call on for questions. To examine their dynamic further, I look at questions from news organizations towards the president during press conferences, specifically the first of President Trump's terms, and President Biden's term, to include a Republican and Democratic administration. I analyzed by coding the tone of the questions, whether the questions correspond to the topic of the president's opening statement, and how often follow-up questions occur. I discovered that questions towards the President with another foreign leader present tend to be less aggressive and stay on the same topic as the opening comments, when compared to press conferences where the president is being questioned alone. News organizations that lean the same way ideologically as the president in power tend to be less aggressive with their questioning, while news organizations that oppose the sitting president ideologically, are more aggressive in their questioning.

Abstract Name: High-Intensity Interval Training and Pain-Related Psychological Factors: A Randomized Controlled Trial

Psychological factors, including optimism, pain catastrophizing, and perceived social marginalization, influence pain sensitivity and how individuals respond to exercise-based interventions¹⁻⁴. However, whether high-intensity interval training (HIIT) interventions can modify these psychological factors in healthy individuals remains unclear. This study explores whether multiple sessions of HIIT alter psychological factors associated with pain perception compared to a single HIIT exercise session. Twenty pain-free participants aged 18 to 50 were randomly assigned to either a Multiple Exercise Session (MES, n=8, 4 high-intensity interval training (HIIT) sessions) or a Single Exercise Session (SES, n=12, 1 HIIT session) over two weeks. Exercise intensity was individualized using a graded exercise test (GXT) performed at 90% of the participant's peak power output. Psychological measures were assessed pre- and post-intervention using validated instruments: Life Orientation Test-Revised (LOT-R), State Optimism Measure (SOM), Pain Catastrophizing Scale (PCS), and Perceived Social Marginalization Scale (PSMS). A two-way mixed ANOVA (group*time) examined differences between protocols. Significant between-group effects were observed for state optimism ($F=5.29$, $p=.027$, $\eta^2=.12$) and life orientation ($F=4.48$, $p=.041$, $\eta^2=.11$), reflecting baseline differences between groups rather than intervention effects. No significant time effects or group $\times$ time interactions emerged for any psychological variable (all $p>.05$) following both single and multiple HIIT sessions. These preliminary findings (ClinicalTrials.gov: NCT07083219) suggest that brief HIIT interventions do not substantially alter psychological factors in healthy adults over two weeks. The stability

of these measures is consistent with their trait-like nature, indicating that longer interventions, higher training volumes, or different populations (e.g., individuals with chronic pain) may be required to observe meaningful psychological change. The observed baseline group imbalances despite randomization underscore the importance of larger sample sizes in future research. Understanding the stability versus modifiability of psychological factors that influence pain perception has implications for personalized exercise prescription and pain management strategies.

Abstract Name: Psychological Distress Among Professionals: Impacts on Performance and Daily Functioning

Mental health significantly influences how professionals think, feel, and perform, particularly under the ongoing demands of their work environments. This study investigated how stress, anxiety, and depression impact professionals' performance and daily functioning, emphasizing the importance of mental-health awareness for managing these challenges. Using a mixed-methods approach, the research combined a systematic literature review with a quantitative survey that assessed psychological distress and coping strategies across daily life and professional activities. Out of 44 survey respondents, 17 professionals completed the study, representing fields such as education, counseling, athletics, music, and medicine. Participants completed standardized assessments of depression, anxiety, and stress during performance, alongside self-reported measures of performance, daily functioning, and coping. Results showed generally low depression levels, but anxiety and stress were more prevalent and closely tied to job expectations and workload. Higher psychological distress was associated with lower performance and reduced daily functioning, indicating that work-related stressors frequently extend beyond professional tasks. Coping strategies varied and included exercise, hobbies, prayer, and setting boundaries between work and personal life. Correlational analyses revealed strong interrelationships among depression, anxiety, and stress, both during performance and in daily life, with higher distress linked to diminished functioning. Certain professions, particularly education, counseling, and music, showed greater variability and higher levels of stress and anxiety, suggesting occupational influences on mental health. Only a small proportion of participants had consulted mental-health professionals, highlighting the need for accessible support. These findings underscore the critical role of mental-health awareness in promoting professional performance, well-being, and decision-making. They suggest that workplaces and professional communities should prioritize mental-health resources, foster healthier coping strategies, and develop targeted interventions to mitigate stress and anxiety, ultimately enhancing both career and personal outcomes.

Abstract Name: Mapping Modernism: Tracing the Market Valuation of Umberto Boccioni's Unique Forms of Continuity in Space

Unique Forms of Continuity in Space (1913), by leading Italian Futurist artist Umberto Boccioni, is a bronze sculpture capturing the vitality and movement of a new, modern world. Beyond its embodiment of the

Futurist aesthetic and philosophy, the original plaster's trajectory reveals the transnational market and networking that shaped how Futurism itself became valued and disseminated. By analyzing the 50-year journey that Unique Forms took from its conception in Milan to its current place in the Museu de Arte Contemporânea da Universidade de São Paulo (MAC USP) in São Paulo, Brazil, this presentation traces the sculpture's development from an avant-garde experiment to a commoditized landmark of 20th-century art. Through cultural and economic research, as well as a digital mapping of the plaster's acquisition history, this presentation critically identifies the different agents within the art market who assessed its value. After Boccioni's death in 1916, the plaster passed through the hands of Filippo Tommaso Marinetti, Futurism's founder, to Benedetta Cappa, a prominent figure of the movement and Marinetti's widow, to Francisco Matarazzo Sobrinho, a Brazilian collector of Italian heritage who donated the plaster to the MAC USP. This presentation explores why Unique Forms was desired by a Brazilian institution, the connection between Italian Futurism and Brazilian modernism, and what influenced Unique Forms' role as a quintessential modern sculpture. The global circulation of Unique Forms epitomizes how the reputation of Futurism in the modernist canon was shaped as much by the transnational art market as it was by its radical aesthetics.

Abstract Name: Investigating telomerase expression in the sea star *Patiria miniata* and its implications on age-related diseases

Exploring telomerase expression may provide insight to alleviate age-related diseases. As humans age, they become more prone to age related diseases— this is in part due to the shortening of telomeres, the protective caps located at the ends of chromosomes that protect our DNA from degradation. Some organisms exhibit a unique mechanism where they are able to maintain telomerase expression, an enzyme that repairs telomeres, throughout their entire lifetime. This study aims to examine telomerase in the sea star, *Patiria miniata*, a largely unexplored organism, to determine if it exhibits this unique mechanism related to healthy aging. A telomerase repeat amplification protocol (TRAP) assay was conducted to measure the enzymatic activity of telomerase. Prior to metamorphosis, samples were collected at multiple developmental stages (blastula, gastrula, and larva). In adults, tissue samples were taken from distinct organs (gonad, digestive tract, and tube feet). The results show that enzymatic activity of telomerase is present in relatively high amounts, in both young and adult sea stars, which suggests *Patiria miniata* possess a molecular mechanism that allows them to remain healthy throughout their lifetime. By studying telomerase activity in *P. miniata*, we can gain valuable insight into the mechanisms that influence healthy aging. Understanding these processes will be valuable to inform future therapeutics aimed at alleviating age-related diseases in humans.

Abstract Name: Sociodemographic and Functional Determinants of Childhood Asthma Prevalence in the United States: Insights from National Health Statistics Data

Background: Asthma remains one of the most prevalent chronic diseases among U.S. children, influenced by socioeconomic, racial, and environmental disparities. Understanding the demographic and social correlates of asthma prevalence can guide targeted public health interventions. **Methods:** We analyzed data from the National Center for Health Statistics (NCHS) Data Query System using responses to the question, “Does [child’s name] still have asthma?” among children aged 0–17 years who were ever diagnosed with asthma by a healthcare professional. Asthma prevalence was stratified by age, sex, race/ethnicity, disability status, family structure, parental education, employment, insurance type, functional difficulty, and poverty level. **Results:** Children aged 12–17 had the highest asthma prevalence (8.5%) compared to ages 5–11 (7.3%) and 0–4 (2.4%, $p < 0.05$). Male children had higher prevalence than females (7.2% vs 5.7%, $p < 0.005$). Black children had the highest asthma rates (11.3%), followed by Hispanic (6.2%), White (5.6%), and Asian (3.3%, $p < 0.05$). Children with disabilities (11.8%) and functional difficulties (9.4%) had nearly twice the prevalence of their counterparts ($p < 0.005$). Higher prevalence was observed among children living with single parents (9.5%), those in households below the federal poverty line (8.6%), and those insured by Medicaid (8.0%) compared with privately insured peers (5.7%). Children from families with lower parental education and unemployment also had significantly higher asthma prevalence ($p < 0.05$). **Conclusion:** Childhood asthma disproportionately affects socioeconomically disadvantaged, minority, and functionally impaired populations. Addressing structural inequities, improving access to care, and enhancing environmental health interventions are essential to mitigate these disparities in pediatric asthma outcomes.

Abstract Name: Designing and Implementing a Virtual Reality Platform for Education Students

This work presents a solution to improve the immersion of students taking the Classroom Management course at Randolph-Macon College. In this course, students participate in role-playing scenarios where one acts as the teacher delivering a lesson, while others act as their students-introducing distractions the teacher must manage. However, it can be difficult for some students to suspend belief and fully engage with these scenarios due to the limitations of a traditional classroom setting. To address this, the project introduces a virtual reality (VR) solution that recreates classroom scenarios in a fully immersive environment. The multiplayer VR platform RecRoom was chosen for its robust set of tools for creating custom virtual spaces or “rooms”, its built-in coding system, and its accessible cross-platform compatibility (including phones, tablets, and Windows computers). In addition, RecRoom’s inclusive avatar customization allows for representation of various ethnicities, cultures and even some disabilities, fostering a more representative and engaging experience. To test the platform, different teaching scenarios were created and performed. The platform has been improved based on test outcomes and notes from tests’ participants. The last tests were successful, with all the features working properly and the scenarios running smoothly. To support users in navigating this new environment, an instructional how-to guide is developed and is being used in the Classroom Management course this Fall. The guide includes instructions on how to perform actions either in virtual reality or on a touch screen device. In the end, the proposed VR solution improves student immersion in classroom management scenarios, while preventing unnecessary distractions. In the future, the platform can be further developed by implementing additional room layouts and improving user intractability with room objects to better simulate real-world classroom dynamics. Also, it could be used in other educational courses where students need to be fully immersed.

Abstract Name: An Agent-Based Model of Monetary Policy Transmission: Comparing Quota System in a Corridor Based Interbank Market

An agent-based model (ABM) of the interbank market is simulated, aiming to test alternative monetary policy frameworks in the context of Nepal. The model is designed based on Bertrand Competition and Nash Bargaining Theory in a perfect information system with variables of liquidity assessment and risk pricing. Two distinct policy regimes are compared: a novel quota-based system, a hybrid price-quantity-based model, and the conventional corridor system. The findings indicate that the Quota model demonstrates superior efficacy in anchoring the interbank rate towards the policy target with greater stability. However, it transfers the cost to the central bank.

Abstract Name: Assessing the Impact of Flavoring Additives on the Quantification of Nicotine in E-Liquids Using High Performance Liquid Chromatography (HPLC)

The accuracy of the reported levels of nicotine contained in e-liquids has been widely studied. Results often show significant inconsistencies in the amount of nicotine reported on e-liquid product labels and the amount of nicotine detected in the e-liquids, but there has yet to be any clear answers to whether or not the labeled nicotine content on e-liquids can be trusted. Due to the lack of regulatory oversight on the production of e-liquids, it is unknown what quality control standards e-liquid manufacturers have for their products. Accepted methods for the quantification of nicotine in e-liquids rely on external standards containing only nicotine for the quantification of nicotine in e-liquids, but this method does not account for the varying components in the matrix of e-liquids. Since e-liquids come in a wide variety of flavors, each has additional compounds that contribute to the matrix of the e-liquid that can potentially affect the quantification of nicotine when relying only on external nicotine standards. In this project, we have assessed the impact of various flavoring additives on the quantification of nicotine contained in e-liquids by HPLC.

Abstract Name: Gene Set Analysis Enhanced: A Large Language Model Approach to Biological Pathway Discovery

Current Gene Set Analysis (GSA) methods often struggle to pinpoint the true biological pathways from

Differentially Expressed Genes (DEGs). These tools rely on rigid statistical models and incomplete databases. This can limit mechanistic understanding of complex biological phenomena, especially when considering tissue-specific gene activity. Our study addresses this challenge by developing a new bioinformatics pipeline that integrates the Large Language Model (LLM) to strengthen pathway discovery in GSA. After statistical filtering of over 600 genes of interest, we found significant enrichment in neural/brain tissue. Using this information, we constructed a Python pipeline featuring a two-stage enrichment process specifically focused on developmental pathways. This process used structured prompt engineering to specifically instruct the LLM to mitigate the possibility of hallucinations and to focus on highly relevant dynamic processes and pathways. The initial stage involved tissue-enrichment filtering to identify a dominant neural signature within the 3'UTR genes. This was followed by a second round of functional enrichment focused on the developmental mechanisms specific to the Central Nervous System (CNS) including, neurogenesis and synaptic pruning. Crucially, a self-verification step was used at each stage, forcing the LLM to check its proposed findings against curated biological databases, ensuring grounded biological interpretations. We anticipate that this LLM-augmented pipeline will significantly outperform current statistical GSA methods and help uncover pathways that are often overlooked. This work establishes a robust framework for using LLM to bridge critical knowledge gaps in genomics research, leading to discovery of previously obscured pathways and offering mechanistic insight into neurodevelopmental processes.

Abstract Name: Assessing the Impact of BH3 Mimetics on Mitochondrial Dynamics in Activated Human T Lymphocytes

The BCL-2 family of proteins regulates intrinsic apoptosis and mitochondrial dynamics. BH3 mimetics are small-molecule inhibitors that engage anti-apoptotic BCL-2 family members to induce apoptosis in malignant cells at the level of the mitochondrion. However, little is known about how these drugs affect healthy immune cells, which contain the same family of proteins but can be resistant to BH3 mimetics. We investigated how BH3 mimetics alter mitochondrial morphology and function in human T cells expanded and activated *ex vivo* in the presence of these compounds. Confocal microscopy revealed that inhibition of BCL-2 with venetoclax or NW-123 promoted mitochondrial fission, whereas inhibition of MCL-1 with S63845 induced mitochondrial fusion. Flow cytometry analysis further showed that treatment of CD8⁺ T cells with venetoclax or S63845 at sublethal doses (IC₂₀) for two days increased both mitochondrial mass and membrane potential. Future work will test whether these morphological changes are mediated through Drp-1 phosphorylation and translocation, and whether distinct BH3 mimetics alter protein-protein interactions between BCL-2 family members and mitochondrial dynamics regulators such as Drp-1, MFN2, and Opa1. This work will uncover how BH3 mimetics alter mitochondrial structure in immune cells, shedding light on their non-apoptotic immunomodulatory potential.

Abstract Name: Visualizing Satb Protein Dimerization Using Bimolecular Fluorescence Complementation Assay

Eukaryotic cells regulate the expression of their genes through a variety of mechanisms including organization of their DNA. Architectural proteins such as Satb1 and Satb2 play a key role in the compaction of chromatin into regions of heterochromatin - where genes are typically silent - and euchromatin - where genes are typically active. Satb1 is involved in T-cell development, and binds to DNA as a homodimer, while Satb2 is critical for osteogenesis and is presumed to bind DNA as a homodimer based on structural homology with Satb1. Although these proteins are usually expressed in a mutually exclusive manner, a few cell types such as embryonic stem cells express both proteins. In these cells, it is possible that Satb1/Satb2 heterodimers are able to form, however this possibility has not yet been tested. Here we utilize a Bimolecular Fluorescence Complementation (BiFC) assay to determine if heterodimers can form. This assay features a yellow fluorescent protein (mVenus), which is split into non-fluorescent halves and individually fused to either the N- or C-terminus of Satb1 or Satb2. Fluorescence is restored when the mVenus fragments are positioned on the same side of a dimer. In this way, the assay can determine whether dimers form and the relative orientation of monomers within the dimer. HeLa cells were co-transfected with pairs of plasmids encoding these constructs and observed under a fluorescence microscope. Fluorescence from mVenus was visible only when both mVenus fragments were fused to the N-terminus of Satb1 and Satb2, demonstrating the formation of heterodimers in a parallel orientation where the N-termini of both proteins are in close proximity to each other.

Abstract Name: Investigating the Biocompatibility of PCL - Bi2O3 Composite Samples for Endovascular Implants

Angiographic visibility of endovascular implants is critical for appropriate placement and avoiding vascular injury. This research investigates the biocompatibility and radiographic visibility of PCL and Bismuth trioxide composite materials for potential applications of endovascular implants. The biocompatibility and cell functions experiment was conducted using Human Umbilical Vein Endothelial Cells (HUVEC). The 10 mm by 10 mm square with 1 mm thick samples were 3D printed using pure PCL medical grade filament as controls and medical grade PCL – Bi2O3 composite filament as study. The cells were thawed out and then allowed to reach 100% confluency after which they were subcultured with appropriate HUVEC media and reagents. The cells were then plated into a 48-well plate with PCL control samples and PCL - Bismuth trioxide samples. The plate was then placed in an incubator and media was changed every 24 hours. After 48 hours of being in the incubator, the cells were fixed using Paraformaldehyde and stained using the PECAM-1 stain as primary antibody and Goat Anti-Mouse Alexa 488 as secondary antibody. The samples were then stored in a freezer for a day, and images were taken using a fluorescent microscope. The images show that samples treated with bismuth trioxide appeared to be proliferating and formed tight junctions around one another. This was made visible by using the PECAM-1 stain. The cells also showed proliferation, and this was quantified using ImageJ software and reported into bar graphs for both the control and the treated samples. Results were compared and there were no statistical differences in the cell functions and viability between the control and study samples. Hence, the result suggested that the PCL – Bi2O3 composite materials could be safely used in the human body as endovascular implants materials.

Abstract Name: FLEXIBILITY AT THE COST OF OPTIMIZATION: AN ANALYSIS OF ATM TILES

An ATM (Arrival Time Monitor) is a crucial tool utilized by all hutchches within the Linac Coherent Light Source (LCLS) at SLAC National Laboratory. It manages two beams, an X-ray and a pump laser. The current ATM operates within a TILE (Table Integrated Laser Enclosure), a modular laser system that is in the process of being installed at LCLS. Our project focuses on reducing the size of the TILE while prioritizing performance, part count, size, cost, and weight. The original TILE design was constrained by a fixed requirement of 11.75" by 34" and a beam height of 3.5 inches. These specifications limited efficiency. The chosen board features 0.19-inch holes every inch for flexibility, with each lens, filter, and mirror equipped with its own clamp and post, leading to increased cost and assembly times. In the second version of the TILE, we plan to eliminate these clamps and posts to improve stability, improve performance, and lower costs. The primary focus will be on improving beam performance by reducing the beam height, which enhances both performance and stability. With a secondary priority being to reduce part count, ultimately lowering costs, assembly time, and weight. The new design significantly enhances handling and maneuverability. Following an iterative process, the first version was remade with only optical mounts and the beam path, leading to brainstorming for the second version. The final design resulted in substantial reductions: beam height decreased from 3.5" to 1.4", parts were cut from 272 to 75—a 71% reduction—while overall size was compacted from 11.75" by 34" to 12" by 19". Further, costs dropped by 7% and weight was cut by 55%. Although still conceptual, the implementation of TILES that prioritize performance could significantly aid scientific research at LCLS.

Abstract Name: Landing Mechanics and Muscle Activation in Modern Dancers

Previous literature has largely focused on ballet dancers and their risk of lower extremity injury. Even though modern dancers differ from ballet dancers in their body movements and biomechanical demands, few studies exist addressing modern dance. In the few previous studies addressing modern dance, tests of postural instability have not been paired with electromyography (EMG). This study integrates multiple tests for postural instability (One- legged broad jump, single-leg drop landing, single-leg hurdle landing, and a single-leg squat) paired with a measurement of muscle activation, EMG, to gain insight into postural instability in modern dancers. Utilizing both the EMG and Force Plate allows for measurement of time to stabilization (TTS) and identifies muscular deficits. This data can be used to provide strength and conditioning recommendations to prevent lower extremity injuries in modern dancers. To date, 12 participants have been fully assessed, ranging in age from 18 to 35 years. Of these, 7 were recreationally active individuals, and 5 were trained modern dancers. Only five participants met the criteria for the single-legged broad jump test, three of whom were dancers. However, based on experience, it seems the only dancers who met the criteria

had several years of training. In both the drop and hurdle landing tests, there also seems to be an experience component to improved time to stabilization (TTS). No pattern was observed in the recreational group. Data from EMG will be analyzed at a later date to identify any differences in muscle activation patterns between the two groups. Further data collection is ongoing to increase the sample size in order to confirm the trend of experience with dancers and TTS.

Abstract Name: AI-Enabled Browser Tool for Early Detection of Cognitive Changes

Early identification of cognitive decline is often limited by infrequent clinical evaluations, which capture only small snapshots of a person's day-to-day functioning. Since people regularly interact with digital media, these online behaviors may offer an unobtrusive way to observe early changes in working memory, processing speed, and attention. Our project explores whether AI-based techniques can help monitor these behaviors in a safe and privacy-preserving manner. As undergraduate researchers, we developed a Chrome browser extension that observes how users interact with online video content and periodically presents brief comprehension questions. The extension records accuracy, response time, and viewing patterns, such as pausing or replaying. These measures provide lightweight indicators of cognitive processes that are often affected in the early stages of dementia. All data is stored locally and can be exported only by the user, ensuring personal control and privacy. In addition to the behavioral data, the system extracts transcripts from the videos and analyzes them with a natural language model to identify emotional tone and recurring themes. This allows us to explore whether the emotional nature of viewed content corresponds with changes in user engagement or response performance. By combining behavioral indicators with linguistic analysis, the tool creates a more complete picture of a user's digital interaction patterns. Our goal is to evaluate whether these combined signals can supplement traditional screening tools and offer clinicians early insight into cognitive changes. This work represents an initial step toward creating accessible, noninvasive technologies that help individuals and caregivers monitor cognitive well-being in everyday settings.

Abstract Name: Developing Cryogenic Infrastructure for SPT-3G+: Next-Gen CMB Instrumentation

Modern cosmology relies on high-precision measurements of the cosmic microwave background (CMB - the faint afterglow of the Big Bang) to investigate fundamental questions about the universe's origin, structure, and fate. One of the leading instruments in this effort is the South Pole Telescope (SPT), which has undergone several upgrades, including the SPT-3G and the upcoming SPT-3G+, to improve sensitivity and resolution. A crucial component of these telescopes is the cryostat, which cools sensitive detectors down to near 0 Kelvin to minimize noise. My project contributes to this larger research effort by repurposing the original SPT-SZ cryostat to serve as a testbed for new optical components for the SPT-3G+ upgrade. Our work fills a critical

gap in experimental cosmology, as this updated telescope has a much denser array of detectors observing at higher frequencies, which will distinguish B-modes (circular polarization patterns in the CMB) caused by primordial gravitational waves or foreground matter lensing. My methodology is to design, manufacture, and install infrared filters and optical components of the SPT-3G+ optics tube into the SPT-SZ cryostat and then test its ability to cool down and block radiation from the outside. I have already completed diagnostic testing of the original cryostat, in which I determined the system can still reliably reach temperatures sub-4 Kelvin. To do this, I integrated a new Lakeshore thermometry system into the cryostat and checked the functionality of the existing diode thermometers. I am currently installing additional diodes to monitor more points within the cryostat. Next, we need to adapt a snout design for the SPT-3G+ cryostat to fit the SPT-SZ system, which will interface with the optics tube. When the optics tube is finished, it will be deployed to the South Pole and installed in the telescope.

Abstract Name: A Different Type of Vampire

This research paper explains the role John Polidori's "The Vampyre" has played in shaping our understanding of vampires, as well as uncovering the origin of this style of vampire. This will provide insight into particular types of human behavior that persist to this very day. By reviewing accounts of the story's inspirations and creation, we can learn more about what characters represent and why it matters. By evaluating the lasting impacts of the story and its derivatives, we can understand more about what the story tells us on the societal scale. This paper asserts that vampires are more than a simple monster; they are a reflection of the worst human habits. As the mysterious, the elite, and the brooding drain the life force of those around them, they become ever-more alluring to some, and more monstrous to others. Monsters have often been created to dramatise real humans and their darker nature, yet vampires retain all the positives of a normal human, and twist them to their dark agenda. From the early days of European folk tales and disease, to Dracula's takeover at the turn of the 20th century, the mystics of Vampirism are something seen time and time again in our society. The work of Polidori has remained influential through countless adaptations, and much of his work has been revered and interpreted. This paper seeks to strip away much of the extra noise, so we might get at the heart of how "The Vampyre" did not simply tell a fantastical tale, but gives a reflection of human sociality.

Abstract Name: Enhancing Chitin Deacetylation with Dielectric Barrier Discharge (DBD) Plasma and

Chitosan, processed through the deacetylation of chitin, is an important biopolymer with applications in wound healing, drug delivery, and tissue engineering. Conventional industrial methods for chitosan production rely on high heat and large amounts of harsh chemicals, making it inefficient and environmentally unfriendly. This study examines dielectric barrier discharge (DBD) plasma as a sustainable alternative to current methods. Our hypothesis is that dielectric barrier discharge (DBD) plasma, especially when paired with carefully chosen operating conditions and additive gases, can reduce the degree of acetylation (DA) more effectively than current methods. Potentiometric titrations with chitin dissolved in NaOH and HCl were initially performed to connect observed pH with DA. However, due to chitin's low solubility, N-Acetylglucosamine, the monomer of chitin, is used as a model compound. Samples were exposed to helium and argon-based DBD plasma jets (16 slpm, 7-10kV/20-50 kHz), under varying operating conditions. Controlled oxygen flows were introduced as additive gases to assess their influence on reactive species generation and deacetylation efficiency. DA was quantified using UV-Vis spectrophotometry, with peak reductions indicating the removal of acetyl groups. Preliminary results show a measurable decrease in DA after two minutes of plasma exposure, with some conditions producing up to a 22% reduction. The introduction of oxygen as an additive gas shows potential for increasing deacetylation, suggesting that gas composition and plasma parameters can be optimized to improve efficiency. Ongoing work focuses on varying additive gas mixtures and plasma operating conditions to determine the most effective strategies for sustainable chitosan production. These findings indicate that DBD plasma is a promising and environmentally friendly alternative to biopolymer processing. Future studies can build on this work to study further plasma-biomaterial interactions.

Abstract Name: Improving Human Skin Explant Viability and Regeneration

In 2024, CeraVe released a survey stating that 40% of people visited a dermatologist that year, though 80% experienced skin concerns. In vitro skin cell and animal models allow researchers to investigate human skin behavior, providing a broadly efficient platform for research, cosmetics testing, and other applications. However, while cell culture and animal models provide insights into skin responses to specific treatments, they do not fully recapitulate the structure or functions of human skin. This project has 2 main aims. Aim 1 will develop a protocol to maximize human skin explant viability in different types of growth media and growth media contact. I will assess multiple growth media to determine which best extends the viability of the explants. Additionally, I will use several methods of medium contact for the explant: direct submersion, porous membrane suspension, gelatin sponge embedding, or agar media embedding. Explant viability will be characterized by RT-qPCR and Ki67 staining and TUNEL assays, which detect signs of proliferation and apoptosis, respectively. By comparing Ki67 staining and TUNEL assays, I will determine which media and form of contact have maximized the viability of the explants. Aim 2 is to examine wound healing in the presence and absence of an injection of the immune stimulant poly I:C using my optimized ex vivo model from Aim 1. Poly I:C is a synthetic dsRNA; in wounded mice, poly I:C injections have shown hair follicle growth, while topical poly I:C has accelerated the regeneration process of wounded human skin. However, poly I:C injections in human skin remain untested. I expect that the injection of poly I:C into wounded human skin will induce regeneration rapidly compared to a control group. These findings will help create a replicable design for researchers to maximize the contribution of scarce resources like human skin explants.

Abstract Name: Stationarity of El Niño Southern Oscillations (ENSO) Teleconnections: Evidence from the North American Drought Atlas and a Reconstruction of the Pacific Walker Circulation

The El Niño Southern Oscillation (ENSO) has a large influence on weather and climate globally, through so-called atmospheric teleconnections. Over North America ENSO teleconnections provide a critical source of seasonal hydroclimate predictability. This predictability is predicated on there being a consistent (i.e., stationary) linkage between ENSO and hydroclimate, our understanding of which is limited by a short and incomplete record of observations. Here we revisit the question of how stationary ENSO's impacts are on North American hydroclimate. To do so, we utilize recent developments from high-resolution paleoclimate, in which indirect (i.e., proxy) observations have been used to extend the record of both ENSO and North American hydroclimate over much of the last millennium. These state-of-the-art paleoclimate reconstructions are the North American Drought Atlas, which uses tree-ring proxies to quantify spatiotemporal variability of hydroclimate, and a multi-proxy reconstruction of the Pacific Walker Circulation (the atmospheric component of ENSO). Here, we examine the relationship between the Pacific Walker Circulation and North American hydroclimate in discrete 100 year intervals (the length of the observational record) spanning the last 800 years. We first correlate the Pacific Walker Circulation to hydroclimate over each 100 year interval, as this quantifies the associated teleconnection pattern, and then we employ pattern correlation statistics to assess consistency of these patterns through time. This approach allows us to determine whether the strength and spatial structure of ENSO's influence on hydroclimate have remained stationary or varied significantly across centuries. We find substantial nonstationarity in ENSO teleconnections and thus investigate the underlying causes. While we cannot rule out that the nonstationarity results from true physical changes in the climate system, it appears likely that paleoclimate reconstruction uncertainty plays an important role in producing apparent nonstationarity.

Abstract Name: Supporting Neurodivergent Learners in Undergraduate Engineering Programs

Engineering courses are often designed with standard lecture formats, fast pacing, and high-stakes assessments. While these structures may work well for some students, they can create barriers for neurodivergent learners, including students with ADHD, autism, dyslexia, dyscalculia, and similar cognitive differences. Research shows that neurodivergent engineering students often bring highly valuable strengths such as systems thinking, creative problem-solving, visual-spatial reasoning, and pattern recognition, yet these strengths are not always engaged or supported in typical classroom environments. Instead, support is often limited to accommodations, which do not address deeper questions of course design, engagement, or belonging. This research explores how undergraduate engineering students experience learning in their programs and aims to identify teaching practices that better support neurodivergent learners. The study uses a mixed-methods approach. First, a survey distributed to collect data on learning experiences, instructional preferences, and perceived challenges. Students who wish to share more volunteer to participate in recorded, semi-structured interviews conducted over Zoom. Interview recordings are transcribed and analyzed

thematically to identify common needs, successful strategies, and opportunities for change. The anticipated outcome of this work is a set of inclusive teaching practices designed to better support neurodivergent learners and likely benefit all students. Rather than focusing on “fixing” students or asking them to adapt to rigid models, this project aims to offer guidance on redesigning learning environments to activate student strengths. This work contributes to ongoing national efforts to broaden participation in engineering and aligns with the National Academy of Engineering’s Grand Challenge to advance personalized learning.

Abstract Name: Optimizing Ovine Arterial ECM Scaffolds for Coronary Artery Bypass Grafting (CABG)

Coronary artery disease, characterized by progressive occlusion of the heart’s vascular supply, remains the leading cause of morbidity and mortality worldwide. Coronary artery bypass grafting (CABG) is the gold-standard surgical intervention for patients with significant coronary occlusions and relies on the availability of suitable autologous vessels to restore perfusion to the myocardium. Unfortunately, a substantial proportion of patients lack usable vessels due to diffuse vascular disease, prior harvest, or comorbid conditions, highlighting the critical need for a reliable, biocompatible, small-diameter alternative graft. This project aims to address this unmet clinical need by developing an ovine (sheep-derived) small-diameter extracellular matrix (ECM) arterial scaffold as a potential off-the-shelf CABG conduit. Because use of xenogeneic tissues in humans requires thorough removal of antigenic components to prevent graft-specific adaptive immune responses, Aim 1 focused on optimizing antigen removal (AR) strategies to minimize immunogenicity while preserving essential ECM structure and function. Ovine carotid arteries were processed using sequential antigen solubilization (AR) and compared with sodium dodecyl sulfate (SDS) decellularization. AR-treated scaffolds demonstrated markedly reduced antigenicity relative to native tissue and SDS-treated controls. Importantly, AR preserved native collagen and elastin architecture and maintained physiologic ECM composition, whereas SDS decellularization resulted in substantial collagen disruption. Mechanical testing further confirmed that AR scaffolds retained native-like tensile strength and elastic properties, supporting their capacity to withstand physiologic hemodynamic forces. Collectively, these findings indicate that AR-processed ovine carotid ECM scaffolds achieve low antigenicity while maintaining critical structural and mechanical integrity. These results support the potential of AR-derived small-diameter vascular grafts as promising candidates for future translational development and clinical use in coronary artery bypass surgery.

Abstract Name: The Influence of High-Impact Practices on Academic and Clinical Success in Traditional vs. Accelerated Mayo Clinic Physician Assistant/Associate (PA) Students

High-impact practices (HIPs)—such as research, global learning, service-learning, mentorship, and leadership—are known to strengthen student engagement, deepen learning, and improve long-term academic outcomes. However, little is known about how these practices influence success in Physician Assistant/Associate (PA) education, particularly for students in accelerated pathways. The Mayo Clinic PA Program recently added a 3+2 accelerated track in which students matriculate at a younger age and with fewer undergraduate years than traditional applicants. Early outcomes suggest performance differences between pathways, including lower first-time Physician Assistant National Certifying Exam (PANCE) pass rates among the first accelerated cohort. These trends raise important questions about whether differences in HIP access or participation contribute to academic and clinical readiness in PA students. This study aims to (1) survey Mayo PA alumni to identify their engagement in HIPs prior to matriculation, and (2) determine which HIPs are most strongly associated with academic performance and perceived clinical preparedness, comparing results across pathways and demographic groups. We developed a survey informed by HIP literature and PA educational competencies, including measures of GPA, first-time PANCE pass rates, and validated self-report indicators of clinical readiness. Following IRB approval, the survey was recently distributed to alumni from the four most recent cohorts. Quantitative analyses will examine relationships between HIP engagement and outcomes, with subgroup comparisons by pathway, age, gender, race/ethnicity, and first-generation status. This project addresses a gap in PA education research by evaluating how experiential learning opportunities shape readiness for rigorous clinical training. We expect that greater HIP engagement will correlate with stronger academic outcomes and increased confidence entering clinical rotations. Findings may inform advising, admissions practices, and curriculum design—supporting more equitable access to HIPs and promoting student success across both traditional and accelerated PA pathways.

Abstract Name: Tracing Land Ownership in Merced's Lost Chinatown 1872-1921

Chinese communities have existed in the City of Merced since its establishment in 1872 up until the 1950s, when the Chinatown was demolished to make way for a section of California Highway 99. Tracing ownership from the creation of Chinatown in 1872 to 1921 reveals how ownership reflected legal precedents in state law and population trends. To better understand land ownership in Merced's Chinatown, I have utilized multiple different primary & secondary source collections to track the land transfers between several figures. This includes newspaper columns noting land transfers, deed sales, and purchase records from the Merced County Clerk's Office, as well as tax data ranging from 1872 to 1899. I supplemented these sources with census data from 1860-1920 as well as fire insurance maps to locate specific structures within the lots being sold and purchased. The results contrast with the California Alien Land Laws of 1913, showing land ownership in Merced's Chinatown was transferred away from Chinese immigrants several decades before any broader legal actions were taken by the State of California. Tracking the ownership of land in Chinatown contributes to a better understanding of Merced's Chinese community and how the space reflects attitudes towards Chinese immigrants at the time.

Abstract Name: Healthy and Unhealthy Depictions of Love in Black vs. White Romance Films

The purpose of this study was to examine how race influences the portrayal of romantic love in films, using the social learning theory as a framework. Specifically, it explored whether patterns of healthy and unhealthy dynamics differ in romantic movies featuring White versus Black main characters. Past research (e.g., Ward et al., 2023) indicates that Black women are often portrayed as the strong Black woman, hypersexual Jezebel, or aggressive Sapphire. These depictions contrast with that of White women, who are more frequently shown as soft, hyper-feminine, which aligns them with the “damsel in distress” trope. Such portrayals can shape audience perceptions, leading to assumptions that Black women are less feminine or friendly. Past research (Moss et al., 2022) also suggests that these stereotypes can increase acceptance of intimate partner violence (IPV) towards Black women and reduce sympathy for victims. This study contributes to the literature by comparing characteristics and relationship quality in romantic films across racial groups. The hypotheses predicted that Black romance films would depict more unhealthy dynamics and White romance films would have higher relationship scores. Three Black romance films and three White romance films with similar plots were selected based on a student pilot where popular romance films were identified. A chi-square analysis in SPSS partially supported the hypotheses. Differences in unhealthy and healthy dynamics between the two races were insignificant; however, overall relationship scores showed marginal significance, with White couples having higher relationship scores. Future studies should examine larger and more diverse groups of films. These results highlight the need for more socially responsible portrayals as well as introduce interventions that can help initiate positive change for couples and families who may base their behaviors on what they have seen in the media.

Abstract Name: Fraction Learning Starts Early: Frequency of Fraction Information Included in First- and Second-Grade Math Textbooks

Fraction knowledge is an essential building block for learning algebra and success in STEM fields (NMAP, 2008). Although formal fraction introduction doesn't occur until third grade (Common Core State Standards, 2010), recent work shows that children have some informal fraction knowledge in 1st grade, which predicts their later math achievement (Viegut et al., 2023). Little is known about where this early fraction knowledge comes from. As a starting point, we are investigating textbooks, as children's math knowledge is closely related to the structure and content of their textbooks (Siegler, 2024). Our primary goal is to discover how often and in which contexts fraction-related information is included in three popular first- and second-grade math textbooks used nationwide in the U.S.: McGraw Hill's Reveal Math, Savvas Learning's enVision Math 2.0, and Amplify's Desmos. Each content page of these textbooks is being coded for containing explicit fraction information (e.g., fraction words or symbols), implicit fraction information (e.g., quarters when referring to money), possible fraction opportunity (e.g., start with 4 bees and 4 bees join; teacher would have to expand on the content to include fraction information), or no fraction information. We expect to find a higher proportion of pages that contain fraction information in second grade textbooks (compared to first grade ones), as well as a higher proportion of fraction information-containing pages in chapters relating to measurement (including lengths, time, money, etc.), geometry, and equal sharing. We also expect to see variability across series, but overall, a higher frequency of implicit and possible fraction information than

explicit fraction information. So far in our coding, we have seen only possible fraction information. Our results will characterize how fraction-related activities are integrated into early curricula, informing future teacher interviews, and identifying plausible opportunities where teachers may expand to build strong foundational skills in fractions.

Abstract Name: The Relationship between Learning Strategies of Students and Intelligence Mindsets

Intelligence mindsets (e.g., fixed or growth) describe beliefs about whether intelligence is static and unchangeable or malleable and can expand over time (Yeager & Dweck, 2020). Individuals with growth mindsets believe intelligence can change over time with effort and work, whereas individuals with fixed mindsets believe intelligence is not malleable. Many studies indicate mindsets are related to academic success of students (Claro et al., 2016). Similarly, study strategies utilized by students are also linked to academic success (de Jesus Silva et al., 2022). We analyze the relationship between study strategy and intelligence mindset. Participants from a college sample will respond to a self-report measure related to their intelligence mindset (Dweck et al., 1995). This measure examines two subscales: growth mindset and fixed mindset. Additionally, participants will complete the study strategy scale to determine their most used study habits (MSLQ; Pintrich & De Groot, 1990). This measures four subscales: Rehearsal, elaboration, critical thinking, and help-seeking strategies. Our research questions include, 1) Are certain study habits predictive of fixed intelligence mindsets?, and 2) Are certain study habits predictive of growth intelligence mindsets? We predict that rehearsal and elaboration study habits will be positively correlated with fixed mindsets and critical thinking, and help-seeking study habits will be positively correlated with growth mindsets. Findings from this study can be used to help educators create interventions aimed at promoting use of study strategies used by individuals with growth mindsets. This may help to improve overall academic outcomes in students.

Abstract Name: Stress and the Oral Microbiome: *S. mutans* and *C. albicans*

Psychological stress has been linked to changes in the oral microbiome. To understand these changes, specific pathogens and bacteria were targeted to investigate the relationship between perceived stress and the oral carriage of *Streptococcus mutans* and *Candida albicans*. *S. mutans* are a primary species found in correlation with dental caries, with previous studies showing evidence of both physiological and psychological stress influencing colonization and activity of the bacteria. *C. albicans* is a pathogen found in the oral cavity and has been detected in the biofilms formed on teeth. Correlations between stress and *C. albicans* have been explored with animal models and are hypothesized to have a significant influence in humans as well. *S. mutans* and *C.*

albicans have been known to interact mutually, increasing each other's persistence in biofilm found on teeth, thus heightening oral disease risk. Because stress has been implicated to cause shifts in bacterial and fungal populations, studying both oral carriages offers more insight into how psychological stress may affect oral health. For this study, college student participants provided saliva samples via sterile cotton swabs, which were plated on two separate media that were selective for *C. albicans* and *S. mutans*, and were incubated and observed for 48 hours. This process allowed student investigators to observe growth and analyze the relative abundance of both microbial species. To further confirm the presence of *S. mutans*, another saliva sample via cotton swab was collected for PCR testing as participants completed the Perceived Stress Scale (PSS). The findings will be discussed in the context of perceived stress and oral health, highlighting the relationship between dental caries and perceived stress. This research aims to contribute to the broader understanding of the human oral microbiome and its psychological influences.

Abstract Name: Flourishing Together: Reciprocal Growth through Peer Mentorship in Wellbeing Education

For nearly a decade, HONR 150 Flourishing: The Applied Science of Wellbeing has served as a cornerstone of the Virginia Commonwealth University Honors College first-year curriculum. This one-credit, semester-long course introduces students to evidence-based practices drawn from positive psychology and cognitive behavioral science to support personal wellbeing, resilience, and purpose. Beyond developing self-awareness and healthy habits, the course fosters community belonging through shared reflection and experiential learning. The incorporation of trained peer mentors has proven to be a key catalyst for achieving these goals. Grounded in Sociocultural Learning Theory and Self-Determination Theory, the program situates learning within a supportive, relational context that emphasizes autonomy, competence, and connectedness. While extensive research has documented the academic and social benefits of peer mentorship for mentees, less attention has been given to the developmental outcomes for the mentors themselves. In this session, a student/mentor team will share research exploring the reciprocal learning that emerges through the peer mentorship model in HONR 150. Drawing upon qualitative feedback and reflective reports collected over five years, analyses highlight consistent themes in mentor growth, including enhanced interpersonal communication, confidence in group facilitation, relational empathy, and deeper integration of wellbeing concepts. Beyond pedagogical and interpersonal gains, mentors developed crisis intervention competencies, including emotional support and deescalation skills. Mentors report that guiding others through discussions of flourishing strengthens their own self-regulation, self-compassion, and sense of purpose. The findings position the HONR 150 peer mentor initiative as a sustainable, low-cost, high-impact model for enhancing both student education and community wellbeing in honors and first-year programs. By emphasizing mutual growth rather than hierarchical teaching, the program exemplifies a proactive approach to holistic student development and offers a replicable framework for institutions seeking to integrate peer educators into the undergraduate experience.

Abstract Name: Building a Sustainable Future: HKUST's Influence on Student Awareness in Hong Kong

This research examines how sustainability initiatives at the Hong Kong University of Science and Technology (HKUST) are perceived and experienced by students, faculty, and staff, and compares these findings with global best practices from PRME (Principles for Responsible Management Education) Champion institutions. The purpose of this study is to understand how effectively HKUST's sustainability efforts raise awareness, foster engagement, and develop sustainability literacy across different faculties, while identifying cultural and institutional factors that shape student participation. Universities globally are expected to serve as leaders in advancing sustainable development, yet research consistently shows a gap between institutional efforts and student involvement. At PRME Champion schools, sustainability is strategically embedded across curricula, student culture, and governance. HKUST, while not a PRME Champion, has developed initiatives such as sustainability core courses, a green campus plan, and student leadership programs. However, limited research exists on how these efforts translate into actual awareness and engagement among the university community. This study adopted a mixed methodology approach, analyzing semi-structured interviews with students, faculty, and sustainability staff at HKUST. Thematic coding identified five major themes: (1) Understanding and Awareness of Sustainability Initiatives, (2) Curriculum Integration and Literacy Development, (3) Student Motivation, Engagement, and Culture, (4) HKUST Campus as a Living Laboratory, and (5) Institutional Support. Findings highlight that while students possess a broad conceptual awareness of sustainability, their engagement remains largely "passive," shaped by convenience, cultural expectations in Hong Kong, and perceived career priorities. Compared with PRME Champions, HKUST lacks systematic SDG integration across faculties, sustainability literacy assessments, and strong recognition mechanisms for student leadership. The results suggest that embedding sustainability across the curriculum, fostering experiential learning, and addressing cultural barriers are critical next steps. This research contributes to the broader discussion on how Asian universities can strengthen sustainability education and align with international best practices.

Abstract Name: The Effects of Early Parental Absence on Adult Romantic Relationships

Research has highlighted the lasting influence of early attachment experiences on an adult's relationships. The present study examines the contribution of early parental absence- occurring before birth or during early childhood- to adult romantic attachment styles and partner trait preferences. 200 participants who had lost a parent early in life filled out the BFI-Short for themselves, their partners, their absent parents, and present parents. They also completed an attachment questionnaire for themselves. Survey data collected was used to assess parental characteristics, relational histories, attachment orientations, and the attributes of current romantic partners. This study investigates how an absent parent shapes an individual's later partner selection. This project also explores whether the narrative context (e.g. silence, idealization, or negative portrayals of the absent parent) mediates or moderates the link between parental absence and adult relationship patterns. Preliminary analyses suggest that early parental absence will contribute uniquely to adult romantic preferences in ways not accounted for by personality traits alone and that partner seeking motives may condition the relationship between attachment and partner selection. The discussion focuses on the psychological mechanisms through which early absence shapes an adult's intimacy.

Abstract Name: The Trump Effect on the Symbolic Economy (Pre-Post Tariff): Semiotic Analysis on Luxury Cars Marketing

This study examines how the reinstatement of President Trump's import tariffs reshapes the symbolic economy of luxury automotive marketing, with a focus on how brand meaning, cultural codes, and value propositions change across different economic conditions. Symbolic economy is the system in which products derive value from both functional performance and symbolic meanings, identity expressions and social signals (Wang et al., 2022). The research question is: As tariffs introduce cost pressures, geopolitical tension, and supply-chain uncertainty, to what extent do luxury automakers adjust how they communicate to their customer base? Prior research indicates that luxury brands remain resilient during downturns by adjusting strategies to shifts in consumer behavior and perceived value (Reyneke et al., 2012). Perceived brand global-ness also strengthens luxury appeal in crisis conditions (Hassan et al., 2015). When governments raise trade barriers, luxury advertisers shift from emotional, image-driven appeals to more factual, simplified messaging that still heightens exclusivity and global prestige through visual cues (Ahn and Mundel, 2018). These insights show how macroeconomic shocks and trade policies reshape luxury brand symbolism, offering a basis for analyzing how Trump-era tariffs may influence luxury car semiotics. The research employs a semiotic analytical framework to compare the semiotic construction of luxury in YouTube advertisements during the pre-tariff period (2022-2024) and the post-tariff period (2025) in luxury automotive messaging across 11 automakers. The method involves identifying emerging patterns using the systematic coding approach outlined by Kucuk (2015), identifying and coding visual, verbal and symbolics elements to extract the basic semiotic codes embedded within brand meaning systems (Kucuk, 2015), how these symbols function within broader cultural narratives. By comparing message structures: verbal cues, color cues, and visual symbolism across both time periods, the study reveals how luxury brands strategically negotiate economic uncertainty and political discourse through their communication strategies.

Abstract Name: Real Time Signal Processing Using Field Programmable Gate Arrays

This project contributes to the High Voltage High Frequency initiative at Idaho National Laboratory, which aims to develop a real-time Non-Intrusive Load Monitoring system capable of identifying electrical behavior on a 145 kV power line. A custom sensor collects current data at 14 million samples per second, producing massive datasets that require a highly efficient analysis method to process. To meet these demands, the project focuses on implementing a signal processing technique to achieve 1 hertz spectral resolution with microsecond-level temporal resolution on a Field Programmable Gate Array (FPGA). The pipeline uses the Sliding Window Infinite Fourier Transform algorithm, which computes spectral information recursively. This approach provides continuously updated frequency bins, supports an unlimited observable spectrogram

window, and avoids the power-of-two constraints that restrict traditional FFT pipelines. These properties make SWIFT better suited for handling high-volume, real time data while preserving the fine spectral and temporal resolution needed for signal analysis. The hardware platform selected is the UltraScale+ ZCU102 FPGA, which provides high parallelism and computational speed needed for real-time spectral analysis. For this project, implementing a signal-processing algorithm on the FPGA follows a three-phase development process. First, an Intellectual Property (IP) core is created to represent the SWIFT algorithm and define its computational behavior. Second, the custom IP is integrated into a larger hardware design that includes supporting infrastructure such as the DMA engine and memory interfaces. Third, programming the System on chip is done to manage data transfer protocols, configure DMA transactions, and handle storage of input and processed data. Completion of these stages is expected to produce a functional real-time processing pipeline.

Abstract Name: Cryptic Diversity in Excirolana Isopods from the Indo-Pacific

With over 10,000 species, isopods are amongst the most speciose crustacean higher taxonomic groups. They are found across all habitats on Earth except polar habitats and those at extreme elevation. Isopods are also known to exhibit high degrees of endemism, perhaps as a result of their biological characteristics that limit dispersal ability and may lead to local speciation. Despite this, many isopod groups remain poorly studied which limits our understanding of the biodiversity of these crustaceans. This is important, as recent molecular studies have uncovered high levels of previously unknown species in various isopod groups including genera such as *Ligia*, *Alloniscus*, *Tylos*, and *Excirolana*. The latter genus is a genus that is found world-wide and that consists of about 15 described and currently valid species. This likely represents an underestimate, as genetic lineages likely representing new and undescribed species have been found in *Excirolana* isopods in the Americas. These findings suggest *Excirolana* isopods in other regions may also harbor such lineages. Herein, we use mitochondrial markers to explore whether *Excirolana* populations from the Indo-Pacific harbor highly divergent genetic lineages that likely correspond to various species. We report the presence of multiple such lineages in a region currently thought to harbor two *Excirolana* species. Our findings expand our knowledge of the biodiversity of this genus specifically and the Indo-Pacific more generally and thus may be of importance for the conservation of biodiversity in this region.

Abstract Name: Digital Aesthetics and Identities of UW Stout Students: Perceptions of Authenticity in Identity-Driven Marketing

Gen Z is often described to value “unfiltered” authenticity on social media yet also engages regularly with aesthetic trends that are reliant on the curation of idealized visuals. Aesthetic subcultures on social media, ranging from curated lifestyle “vibes” to niche anti-modern styles, have become central online communities where Gen Z negotiates self-presentation and community belonging. This research asks, “how do Gen Z college students’ engagements with digital aesthetics influence their identity formation, sense of community, and perceptions of authenticity online?” As an exploratory mixed-method study, this study draws conclusions from a survey of 119 UW-Stout students and a follow-up virtual focus group involving 10 survey participants. Survey data suggests that students feel a general blend between their online and in-person identities, with low pressure to curate personas online, but a strong preference for authenticity on social media. Content cues such as “raw and unedited” visual representations of reality or transparent and vulnerable communication of ideas are the most impactful on students’ positive perceptions of brands and influencers. The focus group contextualizes these survey data patterns by highlighting a nuanced distinction between digital “subcultures” and “aesthetics.” The key distinction students made is that they can be connected to create value-based communities, but aesthetics cannot define entire subcultures. This narrative broadly suggests that, in Gen Z college circles, authenticity is judged more simply on consistency of character. The paradox between their value of unfiltered authenticity and their popularization of curated aesthetics may be partially explained by noting that the social media experience is structured to be curatorial and idealized, but this is not necessarily something that Gen Z likes or approves of despite their participation in it. This study, though limited to self-reported data from UW-Stout students, contributes to cultural conversations on Gen Z’s changing sense of digital identity and community belonging.

Abstract Name: The Sound of Synthesis: Using Data Sonification as a Model for STEM Education in Molecular and Cellular Biology

Although interest in STEM careers is growing, many students face academic barriers, especially when learning abstract molecular biology concepts like protein synthesis and folding, which are often difficult to grasp and not presented in engaging or intuitive ways. To address this, our undergraduate research team developed an interactive educational tool that uses data sonification to make these invisible processes more accessible. The tool translates protein sequences into music, assigning each amino acid a note based on its hydropathy value. This allows learners to “hear” how proteins are built, reinforcing their understanding through auditory and creative pathways. Our software also models disease-associated mutations by introducing audible dissonance, highlighting how even small molecular changes can significantly impact biological function. By blending molecular biology with music, this tool encourages cross-disciplinary thinking and supports diverse learning styles, particularly for students who may not thrive in traditional science instruction. To evaluate the tool’s impact, we conducted demonstrations with middle and high school students, followed by surveys measuring STEM interest, comprehension, and engagement. Preliminary results show increased curiosity, improved conceptual understanding, and enthusiastic responses from participants. These outcomes support our hypothesis that sound-based, interactive learning tools can improve student attitudes and performance in STEM subjects. This work is part of a broader transdisciplinary effort involving neuroscience, music, and genomics. Future directions include expanding the tool into a web-based app, applying it to real genomic data from cancer studies, and developing immersive 3D audio experiences

using AlphaFold-predicted protein structures. Ultimately, our goal is to transform how students experience molecular biology, making science not only more understandable, but more memorable, engaging and meaningful.

Abstract Name: Proteomic Analysis of Mitochondrial Protein Expression in ARID1A-Deficient Ovarian Clear Cell Carcinoma

ARID1A-mutated ovarian clear cell carcinoma (OCCC) is a rare and aggressive subtype of ovarian cancer, with a 5-year overall survival rate below 15%. Current treatments, including paclitaxel and carboplatin, are ineffective due to chemoresistance. Our previous work demonstrated that ARID1A deficient cells develop increased reliance on mitochondrial respiration, suggesting a potential therapeutic vulnerability. While targeting mitochondria is promising in treating chemoresistant cancers, existing mitochondrial inhibitors cause severe side effects due to their broad activity against both cancerous and healthy cells. Moreover, development of FDA-approved mitochondrial inhibitors is hindered by limited data on how ARID1A loss influences specific components of the mitochondrial electron transport chain (ETC). To address this, our study focuses on identifying which ETC components ARID1A-mutant OCCC cells depend on for a more targeted therapeutics approach. Thus, we are conducting whole-cell proteomic analysis on ARID1A-knockout clones derived from the RMG1 OCCC cell line. Metabolic stresses are induced on these cells to shift energy production toward mitochondrial respiration. This strategy activate mitochondrial pathways, allowing us to assess mitochondrial respiration through global proteomic profiling using mass spectrometry. Findings from this study may uncover differences in ETC protein expression in ARID1A-deficient cells, offering more data toward a targeted mitochondrial approach treating ARID1A-mutated OCCC.

Abstract Name: Brown, Queer, and Not from around here: Epistemic Injustice and an Intersectional analysis of Queer International Students in America

Historically, prejudice materializes and perpetuates in many forms. The systemic discrepancies in society steer the prejudice and push marginalized communities away from having a reaction to the absurd experiences which they are subjected to. One such way this happens is through Epistemic Injustice, which refers to the act of undermining an individual in regard to their ability and status as knowers, interpreters, and relayers of knowledge, whilst also violating their status or agency for arbitrary reasonings that are unnecessary to attain, cultivate knowledge. Such an injustice arises from discrimination, biases towards specific races, genders, sexualities, nationalities, and so on. One example would be people of color being

perceived as less credible and more likely to be persecuted and criminalized despite substantial evidence suggesting otherwise. There is a gap between credibility that these individuals are seen to possess in our current societal systems and the credibility everyone deserves inherently. As a brown, queer, and international student in the United States, after having faced various anecdotal experiences from my own intersectional complexities, make me a representative of this sort of injustice. My research aims to construct and clarify the basic framework as well as the state of epistemic injustice faced by queer, people of color, and marginalized individuals in the United States; specifically, by putting the experiences of such non-immigrants in the educational, academic context under a microscope. Through extensive literary review, my research would separate itself from other works in the field by capturing unique experiences and filling in a large gap that exists in the global acknowledgement and understanding of marginalized experiences that have failed to be captured by non-intersectional sources.

Abstract Name: Investigating the implications of VUS in the RNA binding protein FUS

Frontotemporal dementia (FTD) is the most common cause of dementia for individuals under the age of 60. It commonly co-occurs with amyotrophic lateral sclerosis (ALS), and when co-occurring, these diseases cause a combined syndrome called ALS-frontotemporal spectrum syndrome (FTD-MND). This syndrome is associated with a buildup of an RNA-binding protein known as the fused in sarcoma (FUS) protein in motor neurons and brain tissue. This buildup is associated with mutations in the protein that cause protein mislocalization and subsequent cytotoxic effects. This study investigates uncharacterized missense mutations in the PY-NLS domain of this protein, with a focus on arginine to glycine swaps. The goal of this investigation is to determine if a mutation will lead to a cytotoxic buildup of this protein and cause a pathogenic phenotype. The impact of these mutations is assessed using in silico prediction tools, protein modeling, conservation prediction, and molecular dynamics simulations. A total loss of function in this protein will not display a pathogenic phenotype, but a partial loss of function will. Results from these various tools and methods will be used to determine if a pathogenic phenotype will be observed.

Abstract Name: The Socioemotional Impact of Child Maltreatment and the Protective Role of Resilience

Thousands of children in the United States are subjected to child maltreatment each year, often incurring severe damage to their socioemotional development as a result. To better identify and aid these victims, an understanding of the basic socioemotional effects of child maltreatment is critical. Thus, this literature review focuses on the socioemotional impact of child abuse and neglect. Three categories of socioemotional development were studied: personality, attachment, and self-esteem. Articles regarding child maltreatment's influence on socioemotional development were compiled and analyzed to determine abuse and neglect's socioemotional impact. Maltreated children exhibited greater externalizing and internalizing issues and more

traits associated with poor adjustment, especially high neuroticism. In addition, insecure attachment, which can interfere with relationship quality, was highly associated with child maltreatment. Among those who were abused and neglected, self-esteem was also lower. Overall, child maltreatment has a generally negative impact on all three domains. However, numerous children demonstrated resiliency by not showing serious socioemotional deficits. Even so, maltreated children are less likely than nonmaltreated children to show resilience. This lack of resiliency was linked to the personality traits and insecure attachment styles associated with child maltreatment. Ergo, personality and attachment may be promising targets for future interventions aimed at reducing the negative effects of maltreatment. While the socioemotional impacts of child maltreatment are commonly severe, enhancing resiliency by focusing on certain personality traits and insecure attachment styles may be effective in mitigating its devastating consequences.

Abstract Name: Effect of NBCe1 Mutation on Molar Development in Mice

The NBCe1 gene encodes a sodium–bicarbonate cotransporter that plays a key role in maintaining systemic acid–base homeostasis. In humans, NBCe1 mutations result in an unusually low blood pH and various systemic issues, including weakened dental enamel. The renal isoform, NBCe1A, is expressed only in the kidney, where its action stabilizes normal blood pH, while the NBCe1B and NBCe1C isoforms are expressed in non-renal tissues, including ameloblasts, which are responsible for enamel formation. It has been previously hypothesized that low blood pH is responsible for enamel defects. However, in mice, incisor enamel abnormalities are present even when only NBCe1B,C are knocked out, despite normal plasma pH, suggesting a direct role for these isoforms in tooth development. In this study, we analyzed mice lacking NBCe1B,C to determine whether defects in molar enamel also occur independently of systemic acidosis. We hypothesized that NBCe1B,C directly contribute to molar development and that the loss of NBCe1 from ameloblasts would result in significant structural defects in molars. Our objectives were to: [1] compare enamel structure between NBCe1B,C knockout and wild-type molars, [2] identify developmental abnormalities present in the knockout strain, and [3] define the specific role of NBCe1B,C in molar formation. Molar morphology and mineralization were assessed using micro–CT imaging and analyzed in ImageJ. We measured the mesial root length and enamel density of the first molar. On average, root length for the wild type was 0.0137 mm, while for the knockout it was 0.0097 mm. In addition, the average enamel density for the wild type was 1863.6084 MgHA/cm³, compared with 1623.9568 MgHA/cm³ in the knockout. We conclude that NBCe1B,C contributes to normal root growth and enamel mineralization.

Abstract Name: Tensile, Compressive, and Fatigue Behavior of TPMS Gyroid Structures Made from PLA

This study examines the relationship between tensile, compressive, and fatigue of gyroid Triply Periodic Minimal Surface (TPMS) structures with the unit cell density TPMS structures are widely recognized to be useful because of their superior strength-to-weight-ratios, as they can distribute load effectively, minimize the amount of material used, and can be easily additively manufactured. However, limited research has been done to evaluate their mechanical behavior under different types of loading conditions, specifically in monotonic tension and fatigue tension. Gyroid TPMS specimens with densities of 100%, 90%, 75%, 65%, and 50% are additively manufactured and tested in tension, compression, and fatigue. All specimens are manufactured from PLA with the same print parameters. This study aims to unravel the static and fatigue properties of Gyroid TPMS in relation to their unit cell density. Fracture surfaces in monotonic tension and fatigue tension will be observed under optical and electron microscope to further understand the mechanisms for crack initiation and growth in these structures. Results of this study can shed light to applications of TPMS structures in several areas of engineering, such as biomedical, aerospace, automotive, and civil and structural engineering. Further, results of this study set a ground for understanding static and fatigue behavior of other types of TPMS structures than Gyroids.

Abstract Name: Guiding the Emerging Designer: Mentorship Practices That Build Research Confidence and Creative Agency

This paper reflects on my approach to mentoring undergraduate students as they grow into confident, research-minded design scholars. My mentoring philosophy is rooted in the belief that students' lived experiences, cultural backgrounds, and creative instincts are legitimate and vital sources of research insight. In the studio, I guide students in transforming intuitive making into intentional, research-driven design by scaffolding ideation, integrating reflective practice, and encouraging risk-taking through iterative experimentation. Drawing on the Functional, Expressive, and Aesthetic Consumer Needs Model (Lamb & Kallal, 1992), I help students build conceptual grounding for their work, connecting theory to process in ways that feel authentic and personally meaningful. Much of my mentoring focuses on giving students access to museum archives, textile collections, exhibitions, and industry networks so they can experience research as active, hands-on, and connected to real communities. Through structured critique, transparent dialogue about my own research paths, and preparation for opportunities at design exhibitions at professional conferences and on campus research symposia, students learn to articulate their design decisions, frame their inquiries, and see themselves as emerging scholars with something to contribute to the discipline. Over time, students gain confidence in situating their designs within larger cultural and social conversations, developing both research literacy and a strong sense of academic agency. Ultimately, my goal is to cultivate a studio environment where discovery feels possible. Where students recognize their own potential and step forward as thoughtful, critically engaged designers ready to shape the future of the field. Lamb, J. M., & Kallal, M. J. (1992). A conceptual framework for apparel design. *Clothing and Textiles Research Journal*, 10(2), 42–47. <https://doi.org/10.1177/0887302X920100020>

Abstract Name: Pioneering Justice: Prosecuting Genocide from Nuremberg to Rwanda

Following the atrocities of World War II, the International Military Tribunal at Nuremberg indicted major Nazi war criminals. This established a new, international precedent for prosecuting war criminals and directed future international law. Half a century later in 1994, this trial would be used as a model to help shape the International Criminal Tribunal for Rwanda (ICTR) that prosecuted the highest level of perpetrators who organized and carried out the genocide my own family experienced in Rwanda. While Nuremberg provided a structure for prosecution, it did not define genocide or other forms of war crimes. The ICTR expanded early Nuremberg concepts, making it the first tribunal to define genocide and conceptualize sexual violence as a method of genocide. This research will examine the structural frameworks from Nuremberg that influenced future international tribunals. Using the trial records, transcripts, and photographs within the Nuremberg Tribunal Papers and Photographs, 1945–1946, at the University of Kentucky Special Collections Research Center, research will explore how Nuremberg served as an original framework for future international tribunals, such as establishing fundamental concepts like crimes against peace, war crimes, and personal accountability within the realm of international law. Using the Nuremberg and ICTR trial records and transcripts, this research project will link Nuremberg’s basic foundation to the International Criminal Tribunal for Rwanda, which was the first international tribunal since Nuremberg to hand down a judgment against a head of government. ICTR then expanded early Nuremberg concepts, making it the first tribunal to define genocide and conceptualize sexual violence as a method of genocide. Understanding this linkage invites further research into how later courts, notably the International Criminal Court (ICC), build upon the ICTR’s advancements to meet the needs of emerging atrocities.

Abstract Name: Effects of acute stress and estrogen treatment on spatial performance in female rats

Our previous findings suggest the presence of stress response during learning impairs acquisition of female rats across various estrous phases in high-naturally cycling estrogens. The present experiment examined the interactive effects of acute restraint stress and estrogen treatment on ovariectomized (OVX) female rats' ability to acquire, retain, and utilize spatial information using the Open-Field Tower Maze task. Thirty-two ovariectomized (OVX) female rats were used. Estrogen was manipulated via subcutaneous implants containing either estradiol (10% in cholesterol) or cholesterol only (controls). Half of each group underwent 30 minutes of bright-light restraint stress before acquisition training. The final groups were: Estrogen-Non Stress (n=8), Estrogen-Stress (n=8), Cholesterol-Non Stress (n=8), and Cholesterol-Stress (n=8). Spatial learning was assessed using the Open-Field Tower Maze (OFTM). In a circular arena, rats learned to locate food on one of four elevated towers. Trials ended when the rat found their food or after three minutes. Each rat had a consistent “correct” tower across trials, receiving 50 acquisition trials (with/without stress) and 25 retention trials at 48 hours and 21 days (no stress). All trials were recorded and scored for the number of errors before choosing the “correct” tower. An a priori set learning criterion of 8/10 consecutively first-choice correct response was used. Videos were analyzed with EthoVision XT (animal tracking software by Noldus), providing movement and behavioral measures. Stress was found to enhance acquisition of hippocampus-dependent spatial learning in OVX-cholesterol rats but impair it in OVX-estrogen rats. Additionally, stress appeared to reduce the rate of re-acquisition during the 48-hour retention test, with no significant effects

observed on long-term retention. Estrogen-treated rats' learning in stressed environments exhibited greater fear responses compared to cholesterol-treated rats.

Abstract Name: Myc gene region rearrangements in newly sequenced *Drosophila* species

Myc is a proto-oncogene and plays significant roles in cell proliferation, programmed cell death, metabolism, growth regulation, and tissue regeneration. Aberrations which upregulate Myc signaling occur in numerous cancers and are often related to rearrangements within the genomic neighborhood of the Myc gene. Myc family genes encode transcription factors which regulate expression of many other genes needed for normal cell division and are found across different taxa. The study of Myc structure and its genomic neighborhood in closely related species provides unique insights into the changes that affect the gene and its surroundings over the course of evolution. This knowledge is highly valuable in context of the fact that Myc –related rearrangements are frequently found in cancers. This project focuses on identifying and characterizing the Myc gene and its genomic neighborhood in recently sequenced species of the *Drosophila* genus. We hypothesize that the overall structure, location, and genomic neighborhood of Myc would be conserved. To identify the location and the degree of conservation of Myc and its neighboring genes, we analyze their genomic sequences and protein sequences in *Drosophila melanogaster* and the related species. We determine whether the order and orientation of nearby genes is preserved and compare the gene expression data with the automated gene prediction models. Our results indicate that, while a substantial portion of the Myc gene is conserved, parts of the gene structure and significant portions of the surrounding genomic neighborhoods present in the newly sequenced species show extensive genomic rearrangements, including potential inversions, deletions and translations.

Abstract Name: Expanding Education and Access to Weather Satellite Imagery with Affordable Antennas

Access to live weather satellite data is constrained by the high costs of specialized equipment and inadequate signal reception, creating barriers for students and individuals interested in satellite communications. This project addresses these issues by developing a low-cost 120-degree V-Dipole antenna constructed from readily available materials, including 0.5-inch copper pipe, PVC, and 50-ohm coaxial cable. Utilizing open-source satellite tracking, recording, and demodulation software, the design successfully received imagery and data from low-Earth-orbiting weather satellites, such as NOAA-15 and Meteor M2-4. Additionally, the antenna demonstrated versatility by receiving local NOAA weather radio broadcasts at 162 MHz. Compared to a traditional double-cross antenna, the V-dipole antenna delivered a much clearer signal, with less background noise and stronger reception. In our tests near 100 MHz, the double-cross antenna produced weaker results, while the V-dipole achieved about a 13 dB improvement in signal-to-noise ratio, resulting in a noticeable boost in clarity. It means the V-dipole is more effective at capturing cloud cover and infrared imagery broadcasts. Beyond the technical gain, the work demonstrates how affordable, DIY antenna systems

can expand access to real-time satellite data, supporting education, STEM outreach, and communities in remote areas that lack reliable weather forecasting infrastructure.

Abstract Name: A Data-Driven Approach to Fine-Tuning Photochemical Immunogenic Cell Death via Verteporfin-Lipid Nanoparticles

Immunogenic cell death (ICD) is a key mechanism for generating antitumor immunity. Photodynamic therapy (PDT) has been cited as an effective method for inducing ICD by activating photosensitizers with specific wavelengths of light, which leads to the generation of reactive oxygen species (ROS). In this study, we evaluated several attributes that modulate photochemically induced ICD, including photochemical reaction type, cellular uptake efficiency, subcellular localization, and degree of phototoxicity. We formulated a panel of verteporfin-based lipid nanoparticles (V-LNPs) and analyzed their attributes in relation to the exposure of ICD markers HMGB1, HSP-70, and calreticulin. Given the large number of variables analyzed, we leveraged principal component analysis (PCA) to reduce dataset dimensionality and identify key V-LNP attributes associated with ICD marker exposure. Type I and Type II photochemical reactions were assessed through ROS production using the Singlet Oxygen Sensor Green (SOSG) and fluorescent hydroxyphenyl fluorescein (HPF) probes post 690 nm irradiation. Subcellular localization was assessed using confocal microscopy and quantified with Pearson's coefficient values. ICD markers were assessed following light activation at IC25, IC50, and IC75 doses with a panel of V-LNP constructs, and PCA was used to correlate V-LNP type with ICD marker expression. Using PCA, we identified that Type I ROS production, high cellular uptake efficiency, and subcellular localization to the ER and mitochondria were strongly associated with ICD marker exposure at all inhibitory concentrations. Conversely, Type II ROS production was the least associated with ICD marker exposure. These findings provide insights into the multiparametric processes that govern photochemical ICD by V-LNPs. These data-driven studies offer a framework for the rational development of V-LNPs, emphasizing the role of specific attributes in inducing photochemical ICD. Future work will include detailed analysis of cell death pathways and assessment of therapeutic performance in vivo.

Abstract Name: Addressing Loneliness and Cognitive Decline: The Role of Art Therapy and Mental Stimulation in Nursing Centers

Loneliness and depression have impacted over 60% of elderly adults living in nursing centers; however, studies have investigated the effects of art therapy in residents, underscoring its role in emotional well-being, behavior, and reducing cognitive decline. We aim to critically analyze prior studies, determine methodological limitations, and identify key knowledge gaps to inform future research directions and improve non-therapeutic approaches to aging within long-term care facilities. To address gaps in existing research, various peer-reviewed, edited, and scholarly research papers were analyzed. Various restrictive search factors and keywords were utilized to reduce excessive search engine feedback and target studies applicable to the thesis. The findings, results, and conclusions of each study were critically analyzed and expanded upon. Findings suggest that art therapy and cognitive interventions such as arithmetic packets and memory tests, are effective at combating the effects of cognitive decline, especially when used in group settings. By regularly working on math and reading packets, nursing home residents are consistently using problem-solving skills and critical thinking. Art therapy has shown to enhance memory through recall and image visualization and group therapy improves social wellbeing in senior citizen populations. The therapies allow seniors to communicate and create connections with researchers and fellow community members as they complete activities. Through this systematic review of this research, we found that senior citizens that engage with art and cognitive interventions can improve both emotional well being and cognitive function. To strengthen the current research, we suggest that further studies should include large and more diverse participants and explore the combination of different intervention strategies. Further, standardized outcome measures can be used to assess the real effectiveness of these two interventions and can pragmatically benefit our aging population.

Abstract Name: De-influencing You: The Effect of Social Media Comments on Responses to Overconsumption

I aim to analyze how comments on social media overconsumption content could either suppress or encourage our own consumption patterns. The rise of overconsumption on social media is well-documented, but a lack of solutions persists. Researchers recognize comments influence a user's perception of content, but I uniquely evaluate this as an overconsumption intervention. Current solutions/interventions include frameworks, online courses, and social media posts, but these methods are either difficult to scale or time-intensive. Social media comments are accessible, commonly read, and polarizing (encouraging or disapproving of overconsumption), and simply seeing negative comments on social media could inspire people to reduce materialistic desires. However, when positive comments encouraging overconsumption are most prominent, we may further encourage an excessive lifestyle. All data will be gathered through a survey. Participants first watch a 40-second overconsumption video (a skincare organization video with 150+ products displayed) alongside comments under 3 conditions; positive, negative, or a control (no comments). Next, I control for users' connection to the influencer/their lifestyle. Finally, participants complete a 10-minute guided reflection and craft a comment of their own to the discussion. Through topic modeling and sentiment analysis of written content, I evaluate what topics/behavioral traits emerge by condition and the emotional charge of responses to

evaluate alignment of condition (positive or negative) and written response sentiment. I expect the negative group will exhibit stronger reactions than the positive group to overconsumption content, and will more frequently intend to reduce consumption or re-evaluate consumption habits. However, the positive condition may encourage materialistic thinking, with participants lamenting their lesser consumption compared to the video. Final recommendations will be presented to social media stakeholders to display effects of comments, and managers of comment algorithms to display how they prioritize comments influences user response to overconsumption.

Abstract Name: Investigating the Impact of Midkine in Pancreatic Cancer Progression and Liver Metastasis

Pancreatic cancer is the third leading cause of cancer deaths in the United States. As with most cancer-related fatalities, metastasis is the primary cause of death in cases of pancreatic cancer. Patients diagnosed with advanced metastatic disease have a 5-year survival rate below 5%. Our lab previously showed that oxaliplatin (chemotherapy)-treated mice displayed accelerated liver metastasis, and identified Midkine (MDK), a growth factor, as significantly upregulated in midlobular hepatocytes. MDK is a secreted protein involved in various cellular processes such as survival, proliferation, and cancer progression, but its role in pancreatic cancer liver metastasis remains unclear. This study aims to investigate the role of MDK in pancreatic cancer progression and establishment of liver metastasis. Analysis of publicly available data reveal that high MDK expression is associated with the more aggressive basal subtype of pancreatic cancer and MDK is upregulated in liver metastases as compared to primary disease. Additionally, single-cell RNA sequencing datasets from pancreatic cancer patients revealed that pancreatic cancer cells express MDK and high levels of the MDK receptors SDC1 and SDC4. Our data further indicate that human pancreatic cancer cell lines overexpress MDK and its receptors, SDC1 and PRKCD, as compared to normal immortalized pancreatic epithelial cells. Furthermore, pancreatic cancer cells treated with recombinant Midkine (rMDK) showed increased migration compared to the vehicle control, while cells treated with the Midkine inhibitor (iMDK) showed reduced migration. These results suggest that MDK can promote tumor cell migration and potentially support metastatic progression. Our overarching goal is to test if MDK may represent a novel therapeutic target for preventing metastatic progression and, ultimately, improving patient outcomes.

Abstract Name: Investigating the Prevalence of Hypertension, Hyperglycemia, and Associated Lifestyle Factors in the Homeless Population of Dallas, Texas

Cardiovascular disease remains one of the most significant health concerns in the United States, and its effects are often magnified in underserved populations. In Dallas, individuals experiencing homelessness face unique challenges that put them at higher risk for poor cardiovascular outcomes. Limited access to healthcare, unstable living conditions, and inconsistent access to healthy food, safe environments, or substance use resources all contribute to this risk. The UT Dallas chapter of Hearts for the Homeless (H4H) is launching a study to examine how lifestyle factors influence hypertension and elevated blood glucose levels in this vulnerable population. This study will involve collecting blood pressure and blood glucose readings and administering a survey-based questionnaire that asks about participants' lifestyle habits using questions from nationally recognized surveys such as the Pittsburgh Sleep Quality Index, AUDIT-C, and U.S. Household Food Security Survey Module. Data will be gathered through screening events conducted in collaboration with local homeless shelters and food pantry centers throughout Dallas. The goal is to identify specific patterns between behavior and health to better understand the challenges this population faces. H₁: Individuals who regularly smoke or use substances will have a significantly higher prevalence of hypertension ($\geq 140/90$ mmHg) compared to non-users Substance Use $\rightarrow$ Hypertension. Variables: Substance use (binary) vs. Hypertension (binary). Statistical test: Chi-square test (one-sided). H₂: Individuals with poor sleep quality (≤ 4 hours/night or frequent sleep interruptions) will have significantly higher blood glucose levels than those with ≥ 6 hours of uninterrupted sleep Sleep Quality $\rightarrow$ Blood Glucose. Variables: Sleep quality (binary) vs. Blood glucose (continuous). Statistical test: Independent t-test (one-sided). H₃: Individuals reporting inability to afford balanced meals will exhibit elevated blood pressure and blood glucose readings compared to those with higher food security Food Security $\rightarrow$ BP/Glucose. Variables: Food security (binary) vs. BP (continuous). Statistical test: Independent t-test.

Abstract Name: Python-Based Hybrid BB84-Kyber Simulator: Quantum-Resistant DoD Network Keys vs. MITM Attacks

The rapid advancement of quantum computing has brought the "harvest now, decrypt later" problem to the forefront, making quantum-resistant security a national priority for critical infrastructure, particularly within Department of Defense (DoD) networks. This urgent need to achieve quantum-readiness by 2035 necessitates innovative cryptographic solutions. This research simulates a hybrid quantum key system combining BB84 Quantum Key Distribution (QKD) and CRYSTALS-Kyber (a NIST-selected post-quantum cryptography algorithm) using Python and Qiskit. The primary goal is to test the system's resilience against man-in-the-middle (MITM) and denial-of-service (DoS) attacks in a simulated military network environment. The approach merges BB84's inherent quantum detection of eavesdroppers—modeled by simulating light particle states—with Kyber's robust, quantum-safe key encapsulation for data encryption. A custom Python network simulator introduces real-world channel noise, interference, and active attack scenarios, alongside necessary error correction protocols. Key metrics being quantified include Quantum Bit Error Rate (QBER), key generation speed, security strength, and communication delay under combined cyber-quantum threats. Expected results will focus on quantifying the system's performance using these key metrics. We hypothesize that the hybrid system will maintain a significantly lower QBER compared to classical methods during MITM attacks, and that Kyber's key exchange efficiency will enable faster overall communication

latency under DoS pressure than the use of BB84 alone. This approach is anticipated to show strong promise for Army Cyber Command operations in defense against mixed cyber-quantum threats. This simulation effort connects physics-based security with network defense, directly addressing national quantum migration risks using accessible, open-source tools, demonstrating a contribution to military quantum readiness.

Abstract Name: Captain Kidd and the Power of Rhetoric

From Long John Silver to Captain Jack Sparrow, pirates have long held a special place in the Western imagination. When we think of pirates, images of daring sword fights, adventures to far-away lands, and treasure chests piled high with gold come to mind. This popularization disregards the truth of seafaring and obscures that piracy and commissioned sailing was essentially a way for the rich and powerful to make extra money. In this project, I examine how primary sources (from paper and digital archives) and secondary sources (public-facing and academic) present two different version of Capt. William Kidd: the legendary pirate, hanged and gibbeted in London, and the married-with-children, slightly mean New York City privateer. A circumstantial account of Kidd's life written in 1810 describes him as "neither remarkable for the excess of his courage, nor for the want of it." The debate regarding the truth of Kidd's career continues with maritime historians who either conclude that Kidd was indeed guilty of the charges laid against him or exonerate him completely. This debate largely stems from his 1701 trial, when varying perspectives on Kidd's character and activities would converge. The trial ultimately illustrates the power of rhetoric to characterize a legacy. I analyze the testimonies of Kidd's crew, Kidd's own defense for his actions, and the poetry of broadside ballads immortalizing him to reveal the fault-lines of these varying perspectives. This project examines a historical figure with nuance beyond the sensationalized image now cemented in the popular imagination.

Abstract Name: Uncovering the Intersection of Occupational Therapy and Maternal Health: A Study on the Needs, Interests, and Awareness Among Pregnant and Postpartum Women

The emerging field of Maternal Occupational Therapy presents a valuable opportunity to enhance support, resources, and education for pregnant and postpartum women. This study aims to assess the awareness, interests, and needs related to maternal occupational therapy among women in the Oklahoma City metropolitan area. Participants consisted of women within the Oklahoma City metropolitan area who were pregnant or had given birth in the past 5 years. A self-report survey focusing on experiences and perceptions of pregnancy and postpartum regarding participants' most recent pregnancy or birth was given. Data analysis revealed significant gaps in awareness of occupational therapy services and access to relevant support resources. The most significant and consistent gaps shared by participants include awareness of maternal occupational services, consistency of healthcare, mental disorder treatment, and treatments for pelvic floor

complications. These findings highlight a disconnect between available occupational therapy interventions and maternal health needs. In order to truly impact maternal health outcomes and help reduce the elevated maternal mortality rate in the United States, it is essential not only to expand maternal occupational therapy services but also to ensure that women are aware of and can access these resources through targeted education and outreach efforts. Keywords: maternal health, occupational therapy, maternal care, postpartum, pregnancy, Oklahoma City metropolitan

Abstract Name: Student Perceptions of Fairness in AI Policies

Faculty are increasingly addressing AI usage in the class through syllabus policies. However, faculty policies vary dramatically and little is known about students' perceptions of these policies. Using Tom Tyler's conceptualization of procedural justice, this study examines the impact of types of AI policies on perception of justice in the classroom. Surveys that randomly assigned one of three types of syllabi policies, one that encourages AI use, one that limits AI use and one that forbids AI use, were distributed to current college students. Fairness was measured using a modified version of a procedural justice scale. SPSS was used to analyze the relationship between AI policy type and perceptions of procedural justice, as well as how these perceptions varied by race, gender and major. The results will be discussed in this presentation.

Abstract Name: Mentor-Student Partnerships: Applying Evidence-Based Practice through The \$100 Solution

This session highlights the integration of high-impact learning practices within the curriculum through The \$100 Solution, a model that transforms service-learning experiences into research opportunities. Designed for undergraduate students in the Bachelor of Science in Rehabilitation Sciences program, this approach promotes civic engagement, critical thinking, and evidence-based practice by empowering students to identify and address real-world community needs. Working in small groups, students apply the five pillars of The \$100 Solution, partnership, reciprocity, capacity building, sustainability, and reflection, to assess community needs, implement creative interventions, and evaluate outcomes. Guided by the central question, "With this \$100 bill, what can we do to enhance the quality of life in your community?", students design and execute projects that create measurable and sustainable change. The impact of this initiative is assessed across three dimensions: (1) Participation, number of participants, hours contributed, and type of engagement; (2) Student Learning, growth in analysis, problem solving, civic responsibility, and collaboration; and (3) Community Impact, number of community members served, project effectiveness, and sustainability of partnerships. Survey results from students indicate strong outcomes: 100% agreed or strongly agreed that community service increased their awareness of community needs and enhanced their course learning; 97.1% reported greater awareness of personal biases; and 100% agreed that the experience strengthened their problem-solving skills. By merging service-learning with undergraduate research, this faculty-mentored initiative not only advances student learning and community engagement but also fosters a culture of

innovation, reflection, and collaboration, demonstrating how evidence-based practice can extend beyond the classroom to create meaningful societal impact.

Abstract Name: LLM Usage in SCADA Systems

Supervisory Control and Data Acquisition (SCADA) systems support critical infrastructure where security and dependability are crucial, like industrial manufacturing, water treatment, and power distribution. As Large Language Models (LLMs) rapidly advance, there is growing interest in using them to assist SCADA operators by summarizing system data, identifying irregularities, and providing natural-language explanations of system behavior. While these capabilities offer clear operational benefits, integrating LLMs into such sensitive environments introduces significant security challenges. LLMs can respond unpredictably to adversarial prompts, unfamiliar data, or ambiguous instructions, creating risks that are unacceptable in high-stakes industrial contexts. This project investigates the security considerations involved in applying LLMs to SCADA environments. To conduct this assessment, we created a controlled, isolated testing environment using Kali Linux and deployed an open-source LLM locally through Ollama to avoid any external dependencies. Within this setup, we developed a structured prompt-testing framework aimed at evaluating common categories of LLM vulnerabilities. These include susceptibility to prompt injection attacks that could override system-level instructions, the potential for unintended information leakage, and the possibility of bypassing built-in model safeguards through indirect or manipulated prompts. By analyzing how the model behaved across these controlled scenarios, we gained early insights into the types of weaknesses that could impact safety, reliability, and integrity within a SCADA system. These initial results highlight the need for specialized security controls when adapting LLMs for industrial environments. The findings from this phase will guide the next stage of our research: designing a SCADA-focused LLM configured with stronger guardrails, improved predictability, and enhanced protections tailored to critical-infrastructure use.

Abstract Name: Securing the Future Grid: Evaluating Strategies and Challenges to Maintaining Energy Availability Amidst Increased Projected Energy Demand in Texas

As global energy demand rises, exacerbated by heightened electrification, digitalization, globalization, population growth, increasingly severe and frequent extreme weather events, and the scaled development of data storage centers and transmission lines to power emerging technologies, energy grids must adapt to anticipated surges in operational strain. Concurrently, integrating intermittent renewable energy sources into grid systems, an expectation established in response to shifting consumer and stakeholder preferences that prioritize sustainable development, energy availability, and to remain technologically competitive on the

world stage, will introduce variability and complexity to an already labored and unreliable grid. The existing literature present that such challenges are driving more prevalent and prolonged blackouts, with notable cases taking place in Texas, California, and the Northeastern United States in recent years. This paper aims to evaluate the effectiveness of existing strategies to maintain grid security as electricity demand increases by investigating aspects such as the physical reliability, resilience, and load forecasting mechanisms of energy system infrastructure in the state of Texas. To do so, we will conduct a mixed methods analysis with comparative case studies of government reports, the academic literature, and system performance assessments in the United States. Using the E3-US energy-environment-economy model developed by Cambridge Econometrics, we will then forecast the secondary impacts of energy system changes at the state-level, providing insight for economic outcomes and strategic planning. Preliminary findings reveal that key bottlenecks exist in the limited adoption of advanced metering technologies, enhanced storage, regulatory constraints- as in the case of delayed environmental clearances, and underinvestment in adaptive infrastructure modernization- all impeding a transition to a more reliable energy system. Anticipated results will include a lanscape analysis of projected energy demand in Texas, as well as recommendations for regulatory reform and municipal, utility or source operator best practices to support long-term grid resilience and sustainability.

Abstract Name: The Capacity of AI to Assist in Learning: A Rhetorical Analysis

Generative artificial intelligence (AI) has become increasingly popular among undergraduate students for the systems' apparent ability to answer any question imaginable. As such, it becomes necessary to understand how AI systems like ChatGPT affect student learning. Existing research largely falls short, measuring 'learning' according to higher marks or assuming students use AI 'ethically' in practice. In contrast, this paper examines the ways in which AI impacts student knowledge acquisition and critical thinking. It factors in differences between student academic goals, considers studies of expertise and active vs. passive learning, and utilizes Edward R. Tufte's theory of cognitive style to illustrate how AI is detrimental for undergraduate student learning. The research emphasizes the need for prior knowledge and sufficiently developed cognitive skills in order to use AI effectively. The paper concludes by contemplating the long-term drawbacks of overreliance on AI, underscoring both the deterioration of analytical skills and the subsequent fungibility of AI-reliant recent college graduates in the job market.

Abstract Name: United under Torchlight: Valparaiso University's Student Strike of 1970

The student strikes of 1970 were the zenith of student activism, causing the closure of nearly a hundred American universities. Some strikes were deemed a threat to campuses and violently suppressed, such as the shooting at Kent State. While many studies have researched the origin of these national strikes and incidents at larger schools, this paper examines the unique case of Valparaiso University. A small Christian university

that experienced and then quickly diffused, a moment of fiery violence. By examining newspaper archives, this paper argues that Valpo's quick recovery was due to the administration maintaining regular communication channels and working with students on their concerns. Unlike universities where protests became a national tragedy after a careless university response, Valpo protected students' right to protest and the university through collaboration. This case study offers a model for fostering student-admin relations during times of student unrest, which is grounded in dialogue and mutual respect.

Abstract Name: Stories from Healthcare Providers: Narratives Behind Service

Medically uninsured patients in the US continue to experience crucial barriers to accessing healthcare. These barriers are notably higher for Spanish-speaking populations, who must overcome not only financial hurdles but also cultural and linguistic challenges when seeking care. Such inequalities are exacerbated by the reduction in funding for Medicare and restrictive policies for healthcare. These often contribute to poorer outcomes and increased disparities. Many uninsured patients rely on the initiatives of free, volunteer-based clinics running in many communities across the country, to meet their basic healthcare needs. This presentation will provide a close view of the work done by volunteer healthcare providers working in these clinics, with a particular focus on those that work with Spanish-speaking patients. My academic research draws from my experience working as a volunteer Spanish interpreter at several Richmond (VA) clinics, from conducting qualitative research that includes interviews with volunteer physicians, nurses, and administrative staff, and from my knowledge of narrative-based and narrative medicine theory. I will delve into the emotional and interpersonal complexities of serving in this environment by revealing professional experiences and realities through narratives. I will focus on the intercultural competence, empathy, and communication skills required to provide equitable care in under-resourced communities. In this presentation, I aim to emphasize the critical role of volunteer providers in bridging healthcare inequities as cultural mediators and listeners and will advocate for increased understanding of these professionals' work.

Abstract Name: Advancing Sex Education and Health Outcome: The Impacts of Education and Support Programs in Cambodia

In Cambodia, approximately 9% of girls aged 15-19 experience pregnancy, leading to mental health challenges, educational disruption, and limited socioeconomic opportunities. While research has documented various causes of adolescent pregnancy, there is limited synthesis examining how educational barriers, including the pressures surrounding academic failure, intersect with cultural norms, economic pressures, and healthcare gaps to create pathways toward early motherhood. Additionally, the effectiveness of current interventions and the adaptability of evidence-based strategies from other contexts remain underexplored.

This literature review addresses these gaps by systematically analyzing the psychological and socioeconomic effects on Cambodian adolescent mothers. Drawing on reports from NGOs and UNFPA, as well as peer-reviewed research from databases like PubMed and Google Scholar (2014-2024), this study examines how multiple interconnected factors contributed to adolescent pregnancy. The findings reveal that lack of comprehensive sex education, educational pressures that position early marriage as an alternative when girls leave school, cultural norms that frame marriage as family security, and healthcare barriers create challenges where young mothers experience severe emotional distress, educational setbacks, and intergenerational poverty. Critically, this research demonstrates that current interventions, including the Cash Transfer Programme, address immediate financial needs but fail to tackle the underlying educational, cultural, and healthcare factors that perpetuate early pregnancy. The research proposes three culturally-grounded solutions: implementing comprehensive sex education that includes life-planning and reproductive health, strengthening community support systems that provide economic alternatives to early marriage, and improving maternal healthcare access while reducing stigma. By comparing Cambodia's context with the UK's successful Teenage Pregnancy Strategy, this analysis evaluates how evidence-based interventions might be culturally adapted for Cambodia. Future research should evaluate culturally-adapted interventions' long-term impact, investigate media's role in sex education, examine community engagement strategies, and explore policy reforms addressing educational barriers, economic pressures, and cultural factors while respecting family values.

Abstract Name: Evaluating Genipin as a Low-Toxicity Crosslinker for Hybrid Lung ECM Gels to Improve In-Vitro Disease Modeling

Interstitial lung diseases (ILDs) are characterized by fibrosis and stiffening of the lung interstitium, leading to impaired gas exchange and non-physiological cell behavior. The native viscoelasticity and biochemical environments of lung extracellular matrix (ECM) cannot be replicated through traditional tissue culture flasks. Previously we have developed ECM-derived hybrid gels composed of a hydrogel embedded within a cryogel backbone, better mimicking lung tissue microenvironments. However, the majority of hybrid gels utilize glutaraldehyde, a cytotoxic crosslinker that disrupts cell adhesion. To address these limitations, genipin has emerged as a natural crosslinker with significantly reduced cytotoxicity. Despite this potential, its use in lung ECM-derived hybrid gels remains largely unexplored. This project evaluates genipin as a safer, more biocompatible alternative to glutaraldehyde for crosslinking ECM-derived cryogel-hydrogel hybrids. To create ECM gel solutions for both components, human healthy lung tissue is decellularized, lyophilized, cryomilled, enzymatically digested, and neutralized. A fixed ECM concentration and different crosslinker concentrations are used to create cryogels, including a glutaraldehyde control and genipin concentrations of 0.1%, 0.3%, 0.5%, and 0.625%. Pore structure is evaluated using scanning electron microscopy and ImageJ software. Cytocompatibility is assessed using live/dead staining A549 cells seeded into each gel. Mechanical properties are characterized through nanoindentation. In comparison to glutaraldehyde gels, we expect genipin-crosslinked cryogels will exhibit reduced cytotoxic activity and improve cell adhesion while maintaining similar pore size. ECM-derived cryogel hybrids that are safer and physiologically relevant will be defined by identifying the genipin concentration that optimizes biochemical and mechanical properties, including viscoelasticity, stiffness, and water content. The goal of this study is to enhance disease modeling and preclinical testing for ILD research by increasing biocompatibility in lung culture platforms. Future works include incorporation of hydrogel into cryogel backbone and cell proliferation studies.

Abstract Name: Centering Student Voices through the Co-Design of Authentic Mathematics Digital Clinical Simulations for Teacher Practice

Abstract: As calls grow for mathematics teachers to engage in ambitious and equitable instruction, opportunities to rehearse these practices in meaningful ways are essential. Digital Clinical Simulations (DCS) are emerging as a powerful mechanism for this, offering educators a structured environment to step into complex classroom scenarios, react intuitively, practice high-stakes decision-making, and reflect critically on their instructional approach. This vital need for simulated practice, however, leads to a critical and often overlooked question: Who is designing these sophisticated practice spaces, and whose perspectives are embedded within their structure? In most industries user feedback is essential to evaluating effectiveness and promoting innovation. Yet, in education students rarely have the opportunity to provide feedback, much less be part of the design process for teacher practice. To address this gap, we co-designed DCS with students of color, centering their lived experiences and perspectives on equity as the foundation of teacher practice scenarios. Through our design institute, students surfaced their mathematical struggles, insights, and cultural funds of knowledge to shape simulations that more authentically represent the complexities of equitable instruction. Preliminary findings highlight the emergence of *sonder* which is students' recognition that each peer's learning experience is as vivid and multifaceted as their own. After co-designing DCS, students were interviewed to reflect on their experience. Students mentioned how through designing DCS, they fostered a greater sense of empathy and understanding for teachers' work in supporting diverse learners. Students also reported feeling empowered as their narratives became sources of expertise, reframing past challenges as contributions to more humane and contextually grounded teacher learning tools. This co-design approach illustrates how centering student voices within DCS development can strengthen both the authenticity and the equity-driven aims of mathematics teacher education.

Abstract Name: Heat Stress Effects and Electrolyte Balance on Construction Workers in El Paso Texas: A Casey Study

Health issues caused by heat stress have emerged as a global public health concern. In the United States, heat exposure is responsible for as many as 2,000 worker fatalities and 170,000 injuries annually. Construction workers are a vulnerable population, who are recurrently exposed to extreme ambient heat conditions and are at high risk for electrolyte imbalance, heat-related illness (HRI), and organ dysfunction, particularly of the heart and kidneys. Exposure to high ambient temperatures challenges the kidneys' ability to regulate blood pressure, minimize fluid loss associated with severe dehydration, and excrete nitrogenous waste, leading to chronic kidney disease (CKD). CKD is one of the most common and severe complications of heat stroke and frequently reported as an epidemic occurring in regions with extreme heat (40-80% mortality rate), notably affecting young male workers exposed to intense heat conditions daily. In this study, we ask, how does high

workplace ambient temperature affect hydration and electrolyte balance? Methods: An observational, quantitative, descriptive field study was conducted on construction workers (n=4) during the month of September 2025 in El Paso, Texas. Ambient temperature was measured using the ATMOS41 Gen2 weather station. Analysis of hydration status and electrolyte loss was performed through vital signs and sweat tests using NIX Biosensors™. Results: Under a high ambient temperature of at least 85°F, the average sweat rate was 660.2 ± 460.9 ml/hr., and the average electrolyte loss rate was 882 ± 974 mg/hr. Potassium was found to be particularly high in all participants, which could be an indicator of HRI and a marker for early renal tubular disease. Conclusion: These findings can help us recognize early warning signs of electrolyte imbalance induced by ambient heat exposure with potential kidney health effects and guide workplace prevention policies that protect construction workers in high temperature environments.

Abstract Name: The Gendered Heart: Closing the Gender Gap in Heart Disease Diagnosis and Treatment

Cardiovascular disease (CVD) continues to be the primary cause of death for both men and women in the United States, being characterized and treated in a historically male-centric manner. This research paper will address the disparities in risk factors for heart disease between genders, gender differences in diagnosis, and gender differences in management/treatment, thereby demonstrating the critical importance of incorporating sex specific factors into the field of cardiology. It has been demonstrated that lifestyle changes such as physical activity and smoking cessation can reduce CVD risk universally. This signifies a necessary shift toward being proactive in the prevention of CVD. However, this does not prove that these universal factors will yield fruitful outcomes when the stigma of unique female risk factors are ignored. Unique female risk factors include aspects of reproductive history (i.e., pre-eclampsia and gestational diabetes) and anatomical differences (i.e., microvascular arterial structure and distinct genetic regulation). Most importantly, this research will demonstrate the gender gap in clinical practice, which includes the underrepresentation of women in clinical trials, delayed diagnoses resulting from atypical symptomology of women, and less aggressive medical management (i.e., lower guideline-recommended medication and diminished cardiac rehabilitation enrollment). These systemic biases provoke this disparity and therefore contribute to higher mortality rates and poorer long-term outcomes for woman than their male counterparts. To eliminate the gender gap and decrease CVD mortality, cardiology must move beyond general models. It is recommended to enhance the development and implementation of sex-specific diagnostic thresholds, risk stratification tools, and comprehensive, holistic care protocols that take into account the unique biological risk factors for women, as well as any biases that are part of institutionalized processes.

Abstract Name: First Responders and Communicating with Individuals with Dementia

First responders, such as police officers, firefighters, EMTs, and other emergency personnel, often interact with individuals who may be confused, frightened, or unable to communicate clearly during a crisis. Because

of this, the way first responders communicate can greatly influence the safety, comfort, and overall outcome of an emergency situation. As individuals age, the likelihood of developing a mental illness such as dementia or related neurocognitive conditions increases. The number of people living with the condition is projected to rise by nearly triple by 2050, from 55 million to 139 million worldwide. This study aims to better understand how first responders perceive their preparedness and communication strategies when working with individuals who have moderate to severe dementia. Using an online survey, first responders from multiple departments answered questions about their past experiences, the type of training they have received, and how confident they feel when responding to calls involving people with significant cognitive impairment. Initial results show that communication approaches vary widely across departments. Many first responders reported limited or inconsistent training on how to communicate effectively with individuals experiencing severe dementia. However, those who had received specialized training, either through their job or personal experience, expressed more confidence in their ability to communicate safely and effectively during real emergencies. These findings highlight a need for more consistent, accessible, and role-specific dementia training for first responders. Improving training in areas such as communication strategies, de-escalation, safe assistance, and reducing confusion during transport may help responders feel more prepared and may improve outcomes for individuals with dementia. By identifying gaps in current knowledge and training practices, this study provides insight that can support the development of better training programs. Strengthening first responder competence in this area may lead to safer interactions and more effective emergency care for people living with dementia.

Abstract Name: Dementia: Community Education Wider Impacts

Dementia is not a normal component of aging; it is a clinical syndrome characterized by progressive decline in memory, communication, reasoning, and other cognitive functions resulting from neuronal damage. Common etiologies include Alzheimer's disease, vascular dementia, frontotemporal dementia, and Lewy body dementia. Although most forms are irreversible, certain cases linked to medication effects, metabolic disturbances, infections, or depression may improve with appropriate treatment. Dementia affects multiple domains of daily functioning, influencing attention, problem-solving, behavior, and social engagement. As of 2024, fourteen modifiable risk factors — including untreated hearing loss, hypertension, smoking, and social isolation — have been identified as significant contributors to dementia risk and can be targeted through early intervention. As part of this project, I contribute to community-based prevention efforts by creating bilingual (Spanish and English) educational videos that have received positive public feedback, and by administering the Montreal Cognitive Assessment (MoCA) to older adults as part of early cognitive screening initiatives. In addition to reporting video development process, frequency of use, inquiry about MoCA screenings, findings will also identify themes from the video feedback. Together, these efforts underscore the importance of accessible education and proactive screening in promoting brain health and reducing dementia risk.

Abstract Name: Improving disaster aid supply chain performance in domestic hurricane responses: Where AI Comes In

Hurricanes are historically the deadliest and most destructive weather disasters in the United States, according to the National Oceanic and Atmospheric Administration (NOAA). Because logistics activities can account for up to 60 to 80% of total humanitarian costs and past disasters have shown that weak logical strategies can create bottlenecks and poor decision-making, this research evaluates whether Artificial Intelligence (AI) can strengthen these processes. It explores the question: “How can Artificial Intelligence-driven methods improve disaster aid supply chain performance in domestic hurricane responses?” AI has demonstrated strong capabilities in interpreting complex, multidimensional data in dynamic environments such as supply chain disruption, making it well-suited for disaster contexts. Considering up to 30% of delivered aid lost due to inefficiencies in past crises, opportunities exist for AI to enhance resource prioritization, allocation, and overall responsiveness. This study uses a comparative analysis to examine the differences in decision processes by Artificial Intelligence. A large language model (LLM), OpenAI’s ChatGPT-4, was tested by prompting it to develop a response plan for simulated hurricanes based on historical meteorological data from NOAA’s National Hurricane Center Data Archive and financial constraints from the American Red Cross’s publicly available Consolidated Financial Statements. The LLM’s recommendations were then compared to the American Red Cross’s Post-Hurricane Response reports. The goal is to assess whether the LLM proposes more efficient or adaptive strategies than those used historically. If so, the findings may support future integration of AI-assisted decision-making within government and non-profit disaster response operations.

Abstract Name: Dehumanized Desire: How Pornography Shapes Perceptions of Womanhood

This research explores how women’s representation in pornography has affected attitudes toward women in modern society. With the evolution of pornography from magazines and VHS to today’s digital platforms, sexual content has become more accessible than ever. Its recurring portrayals of women as objects of consumption rather than autonomous beings contribute to the perception of women as inferior, subhuman, and objectified. Mainstream porn often depicts women through themes of degradation, objectification, and infantilization. These portrayals are especially harmful to youth, as they negatively shape their perceptions of gender, intimacy, and the value of women in everyday life. These influences function on both conscious and subconscious levels, though often going unnoticed. Analyzing these depictions is necessary as digital media becomes an increasingly integral part of global society. This research examines how these portrayals affect Millennials and Gen Z’s ideas of gender and intimacy, and how access to sexual content at a younger age influences their social development and views of intimate relationships. Conducting surveys and interviews with Millennial and Gen Z participants provides insight into how exposure to pornographic stereotypes influences their expectations, behaviors, and attitudes. This analysis also assesses how existing research explains its findings, the language scholars use when discussing women’s portrayal in pornography, and how scholarly bias may overlook key perspectives. Understanding these influences offers important context in guiding strategies that support healthier social and relational development among youth exposed to sexualized media. Together, these elements demonstrate how pornography reinforces misguided patriarchal understandings of women, fundamentally highlighting the urgency for culturally informed media literacy and more accurate representation in digital spaces.

Abstract Name: An Assessment of Interactive Fiction Software as a Teaching Tool for Counseling Skills

Currently, there is an increased demand for quality mental health providers due to widespread burnout, rising mental health needs, and insufficient funding. Additionally, there has been a growing reliance upon technology-based counseling and mental health supports such as telemental health due to COVID-19. However, there is a lack of focus on integrating technology-based teaching tools that align with those utilized by telemental health professionals. While empathy development is essential for mental health professionals, a gap exists between the spheres of teaching empathy and technology. Therefore, this study seeks to identify the use of interactive fiction software as an effective tool for counselors' education and skill development. More specifically, the researchers of this study are interested in how the interactive nature of a choose-your-own-adventure counseling fiction software tool can impact student learning experiences, given the power and moral decision-making qualities inherent in this tool. Prior research on this topic has examined various age groups and fields such as nursing and medicine; however, there is a gap in the literature specifically addressing undergraduate counseling students, the focus of this research. This study employs a mixed-methods design, incorporating interviews and survey responses from students and faculty of Elon University's counseling families and individuals course in Fall 2025. The study aims to identify higher levels of engagement, reflection, and preparedness for future client interactions among respondents, which is crucial in discussions regarding the development of future educational tools. Findings from qualitative data analysis of students' reported experiences with the interactive tool will help shape future counseling pedagogy.

Abstract Name: Identifying RNA Splicing Changes During Alcohol Withdrawal Using an Optimized RNA-Seq Analysis Pipeline

Alcohol use disorder (AUD) produces lasting changes in the brain, including shifts in gene expression and RNA splicing that contribute to the neuroadaptations observed during withdrawal. The ventral hippocampus, a region involved in motivation, emotional processing, and stress regulation, is particularly sensitive to alcohol-related molecular changes. To investigate these processes, this project analyzes RNA-Seq data from the ventral hippocampus of rats exposed to chronic alcohol followed by withdrawal, with a focus on identifying transcript-level and splicing-related alterations. A reproducible RNA-Seq pipeline was developed and refined using tools such as STAR, FeatureCounts, edgeR, and WGCNA, enabling efficient processing of more than 50 million sequencing reads across 25 datasets. Pipeline improvements increased runtime efficiency by 25 - 40% and strengthened consistency across analyses. Through statistical modeling, dimensionality reduction, and functional enrichment approaches, the analysis identified expression and splicing patterns associated with neural signaling and stress-response pathways that may underlie behavioral and physiological changes during withdrawal. To support continuity within the research group, a complete RNA-Seq training guide was also created to standardize data processing and improve reproducibility across projects. Overall, this work advances efforts to characterize transcriptomic changes associated with alcohol withdrawal and provides an optimized computational framework for future neurogenomics studies. The project highlights how integrating efficient computational pipelines with transcript-level analyses can deepen our understanding of AUD-related molecular adaptations and offers attendees insight into both the biological findings and the data-science approaches used to uncover them.

Abstract Name: Parent-Performance Discrepancies in Executive Functioning Among Pediatric Oncology Patients

Pediatric patients with non-central nervous system (CNS) origin cancers are at elevated risk for executive functioning (EF) difficulties due to chemotherapy neurotoxicity, stress, and early cognitive disruptions. EF challenges affect daily life, school performance, and independence skills. These difficulties are best quantified with self-report measures and objective cognitive testing; however, the degree to which these methods align in childhood cancer survivors remains understudied. This study investigated the correspondence between parent-reported EF and performance-based EF tasks among childhood survivors of non-CNS cancers receiving neuropsychological evaluation. Parent perceptions of EF were measured using the BRIEF Global Executive Composite (GEC), reflecting behavioral regulation and metacognitive functioning. Performance EF was assessed using two D-KEFS tasks aligned with BRIEF domains: Color-Word Inhibition (inhibitory control) and Design Fluency Total Correct (nonverbal cognitive flexibility). Demographic variables included age, sex, parent education, and cancer diagnosis. 61 participants were included (mean age = 12.1 years, female = 51%). Diagnoses included leukemias (54%), lymphomas (18%), and solid tumors (28%), with acute lymphoblastic leukemia (ALL) representing the largest subgroup (51%). Results demonstrated no significant associations between BRIEF GEC and either Color-Word Inhibition ($r = -.13$, $p = .33$) or Design Fluency ($r = -.09$, $p = .49$) utilizing Pearson correlations, indicating weak correspondence between parent-reported and performance-based EF. A paired-samples t-test comparing standardized scores showed no significant difference in impairment between methods, $t(56) = .03$, $p = .97$. A regression predicting BRIEF GEC from performance EF and demographics was significant, $F(5,51) = 2.68$, p

= .032, but neither D-KEFS task predicted parent-report EF; only parent education was significant ($\beta = -.39$, $p = .004$). Findings demonstrate limited alignment between parent perceptions of EF and structured EF task performance, suggesting that each captures distinct aspects of cognitive functioning. Results highlight the need for multimethod EF assessment in pediatric oncology to support accurate identification of cognitive challenges and clinical care.

Abstract Name: Differential Associations Between Narcissistic Antagonism, Narcissistic Neuroticism, and Negative Empathy

Narcissism is reliably linked to increases in cognitive facets of empathy– the ability to understand the emotions of others. The relationship between the two facets of Narcissism (i.e., Narcissistic Neuroticism and Narcissistic Antagonism), which are associated with externalizing behaviors and negative empathy, is the ability to understand or vicariously experience the negative emotions of others, remains understudied. Participants ($N = 191$) completed self-report measures of Narcissistic Neuroticism, Narcissistic Antagonism, and negative empathy. Correlational analyses were conducted to examine the associations between Narcissistic Neuroticism and Narcissistic Antagonism related to negative empathy. A statistically significant positive correlation emerged between Narcissistic Neuroticism and negative empathy ($p = .002$). A numerically positive, but not statistically significant, correlation emerged between Narcissistic Antagonism and negative empathy ($p = .358$). Counter to our pre-registered prediction, the positive association between Narcissistic Neuroticism and negative empathy was not statistically significantly stronger than the association between Narcissistic Antagonism and negative empathy ($p = .05$). Importantly, we were underpowered to detect the size of the difference between the two dependent correlations (i.e., $r = 0.16$). Future research might use experimental manipulations of affect or examine empathic behaviors to further examine these relations.

Abstract Name: Listening to Voices: Student, Faculty, and Administrator Perspectives on Course-Based Undergraduate Research Experiences (CUREs)

Course-based Undergraduate Research Experiences (CUREs) embed authentic research projects into existing courses, enabling students to contribute to real scientific investigations while developing transferable skills and earning course credit. CUREs expand access to research opportunities for students that were once limited, allowing broader participation in research and project-based learning. While prior studies have emphasized student outcomes, fewer have qualitatively examined how students, faculty, and administrators with and without CURE experience perceive the implementation and impact of CUREs. Understanding these

perspectives is essential, as faculty play a central role in course design and delivery, administrators influence institutional funding and resource allocation, and students are the recipients of these experiences. This NSF-funded study investigates how students, faculty, and administrators in STEM fields at Kennesaw State University view the benefits, challenges, and logistics of integrating CUREs into the curriculum. Seven focus groups were conducted with participants who have and have not been involved in CUREs. The qualitative data are currently being analyzed in NVivo using a structured codebook encompassing themes such as student benefits, accessibility, institutional support, teaching logistics, and barriers encountered before and during a CURE, among others. Although analysis is ongoing, this study seeks to identify areas of alignment and divergence across participant groups to better understand the opportunities, constraints, and long-term sustainability of CUREs within STEM education. By examining these perspectives, this research aims to deepen our understanding of how CUREs can be better designed and supported, ensuring that both students and faculty benefit from meaningful, accessible research experiences.

Abstract Name: Shifting Baselines in Urban Nature: Long-Term Monitoring of Zebra Longwing Butterflies

Insect populations are declining globally, yet these losses often go unnoticed in everyday landscapes. Urban development accelerates this disconnect, fostering shifting baseline syndrome: the tendency for each generation to accept a progressively degraded environment as “normal,” making long-term biodiversity losses less noticeable. The Florida International University (FIU) Nature Preserve is a small forest fragment surrounded by campus infrastructure. From 2011 to 2017, its forested area decreased by about 33%, shrinking the perimeter from 998 m to 703 m. During this period, a community science project used mark-recapture methods to monitor zebra longwing butterflies (*Heliconius charithonia*), revealing population declines alongside habitat loss. In 2025, we repeated the survey using the same approach. Forest measurements confirmed no further clearing since 2017, yet the estimated population was only 32 individuals, lower than the minimum recorded in 2018. This suggests continued decline despite habitat stabilization. By combining updated population estimates with historical imagery, this study demonstrates how infrastructure expansion and fragmentation can have lasting impacts on urban biodiversity. Beyond documenting changes, the project engages students and local residents in fundamental research, emphasizing the conservation value of small urban preserves and the risk that shifting baseline syndrome will normalize butterfly population declines.

Abstract Name: The Latino Virginia Oral History Project: An Analysis of the Latino Immigrant Experience Through Resilience

Based on a report conducted in recent years from the National Institute of Minority Health, from 2019 to

2023, the percentage of Latinos in Virginia has increased to 10.6%. With this comes a blend of culture and a shared experience among Latinos who face different realities from their home of origin compared to the United States. The Latino Virginia Oral History Project aims to preserve these stories of resilience and showcase the various ways Latinos have contributed to this country and our state of Virginia. Through our interviews, participants recount their stories of childhood, migration journeys, hardships, and their interactions within those of the Latino community and those in the greater public. Our digital archive is a repository for the experiences of Latinos to document the community for engagement and enrich the archives to serve multidisciplinary research. In light of this objective, our research question is as follows: How does resilience among Latino immigrants in Virginia serve as a lens for understanding the shared structural challenges faced by Latino immigrants and Latino communities? Secondly, we aim to understand how the experiences of Latinos in Virginia intersect and how they relate in resiliency. Shining a light on the topic will raise awareness and increase public understanding which in turn should encourage behavioral changes, shift the stigma surrounding Latino immigrants, and foster social or political change. In this study, we will be focusing on 5 participants from our project to further explore the effects of resilience when facing similar challenges among Latinos. We have decided to use a smaller sample size to delve deeper into each story and components of resilience. Possible findings may include difficulties in employment other than labor, language barriers, family struggles, trouble adapting, and financial difficulties while immigrating to the U.S.

Abstract Name: Evaluation of Chronodisruption in Duchenne Muscular Dystrophy Patients and Mice

Background: Duchenne muscular dystrophy (DMD) is a progressive, X-linked neuromuscular disorder that is caused by a pathogenic variant in the DMD gene, resulting in the failure to produce a functional dystrophin protein. DMD can result in muscle atrophy and fibrosis, cardiomyopathy, and respiratory failure. Chronodisruption refers to the chronic disruption of the body's circadian rhythm that is moderated through transcription of thousands of CLOCK-controlled genes. These genes regulate muscle function and mitochondrial metabolism, which are both severely disrupted in DMD-affected tissues and organs. **Hypothesis:** While dystrophin loss is the cause of DMD, circadian rhythms also affect muscle health, and their disruption might worsen DMD patient outcomes. **Methods & Results:** To study circadian disruption in DMD, the expression of circadian rhythm genes and the circadian transcriptome in wildtype and mdx (DMD) mice were analyzed. Diurnal behavior analysis was also performed to study activity during light phase, activity onset, and quantified by a periodogram power score. Mdx mice exhibited increased activity onset, phase shift of activity onset, increased activity in subjective night, and significantly less robust rhythmic behavior. In parallel DMD patient studies, we used wrist wearable actigraphy monitors to measure activity and chronicity in DMD ambulatory and non-ambulatory patients of mixed aged cohorts. Significant sleep disruption, decreased sleep duration, as well as poor sleep efficiency in DMD patients were observed over a continuous two-week interval in correlation with age and dystrophic disease progression. **Conclusion:** DMD mice have progressively disrupted circadian rhythms. Our findings provide initial evidence for

investigating a novel role of dystrophin in disrupting the circadian rhythm in DMD mice and patients. Further experimentation through RNA-sequencing and Dmd conditional knockout (KO) mice may provide insight into how circadian rhythm impacts DMD disease progression.

Abstract Name: Dominance From Within and Abroad: U.S. and Russian Socio-Political Memory in the Aftermath of Nuremberg

Following the end of World War Two, an international tribunal was held in Nuremberg, Germany to prosecute Nazi officials for their crimes against humanity during and prior to the war. In the aftermath of the verdicts, the Soviet Union and United States constructed distinct socio-political memories of the Nuremberg Tribunal and WWII. In both countries, images shaped the constructed and institutionalized collective memory of these historical events. The formation of the USSR's representation of the war, named the Great Patriotic War, served as a tool for the Russian Soviet Republic to unite social memory within multiple Soviet Republic identities. The United States, comparatively, used its representation of its involvement in WWII to justify and establish military and political presence abroad. Utilizing the archival photographs in the Nuremberg Tribunal Papers and Photographs collection at the University of Kentucky Libraries Special Collections Research Center, this research will explore the difference between the creation of socio-political memory in the United States and Soviet Union in the aftermath of the Nuremberg Tribunal. Comparisons between Russian and American popular photographs, films, and other media from 1945-1950 and 2020-2025 will be used to illustrate differences in the formation of social-political memory between the two countries. This investigation will provide insight into tensions in modern-day U.S.-Russian political relations, opening avenues for understanding and diplomacy.

Abstract Name: Developing Efficient Segmentation and Radiological Tool for Stroke Outcome Prediction

Acute ischemic stroke (AIS) is caused by an arterial blood clot that reduces oxygen supply and potentially causes permanent neurological damage. Millions suffer from AIS annually, often leading to disability or death. Early prediction of patient outcomes is essential for guiding treatment decisions and rehabilitation. Traditional methods, such as the Alberta Stroke Program Early CT Score (ASPECTS), are often qualitative, semi-automated, and time-consuming. They rely on subjective assessments that require human intervention, making them susceptible to inter- and intra-reader variability. This project evaluated the deep learning model SAM-Med3D for the automated segmentation of intracranial and ischemic brain regions, aiming to improve stroke prognosis. A comprehensive dataset was first assembled, containing over 500 scans of stroke patients treated between 2019 and 2022 at participating medical centers. The dataset, including images and ground truth labels, was organized into two categories for the two stages of required segmentation: stage one for

identifying total brain volume (TBV) and stage two for isolating cerebral infarct volume (CIV). The datasets were preprocessed by resampling and standardizing input shapes through zero padding and resizing. TBV data were split into 363/91/45 cases (train/val/test) and CIV data into 106/27 (train/test). The two-stage SAM-Med3D models were trained. Models were trained for 100 epochs with a batch size of 4 for each task. During evaluation, the TBV model achieved Dice scores of 0.9231 (validation) and 0.9373 (testing), while for CIV, it yielded a test Dice score of 0.4146. Overall, the findings suggest that the model performs well in preliminary testing and holds promise for enabling physicians to quantitatively assess stroke severity while reducing human intervention and expediting the process. However, a limited number of infarct-containing slices per case reduced the effectiveness of CIV segmentation.

Abstract Name: Characterization of Expression and Localization of Downstream Proteins Following Ninein Deletion in the Central Amygdala

Anxiety disorders are associated with an increased risk of developing Alcohol Use Disorder (AUD). The Miles Lab previously identified microtubule-binding protein Ninein (Nin) as a candidate gene for the anxiolytic response to an acute dose of ethanol. Here, we hypothesize that deletion of Nin in neurons in the central amygdala (CeA) will alter the localization of downstream proteins involved in inhibitory synapses. Male and female Nin Flox mice were injected with a control virus (AAV8-hSyn-eGFP) or deletion virus (AAV8-hSyn-cre-eGFP) to delete Ninein in the CeA. Prior PCR results validated Cre deletion of the floxed Ninein exon. Animals were transcardially perfused, and brains were collected and processed for immunofluorescence. We stained for Ninein to validate our knockout model and downstream proteins, including Beta-III Tubulin, Gephyrin, and Dynein, to see if the deletion of Ninein affected downstream protein localization/expression. Surprisingly, we observed no overall decrease in Ninein staining in Cre mice, but did see changes in Ninein localization from a speckled staining to a more diffuse, cytoplasmic staining. Changes were also identified in Beta-III Tubulin, Gephyrin, and Dynein expression as a result of Ninein deletion. In normal cells, Beta-III tubulin had a different localization pattern: more circular and organized staining. In the deletion cells, Gephyrin had a more diffuse and less clustered staining when compared to normal cells. Dynein showed brighter overall staining and no localization differences. While we were not able to validate that our knockout model worked based on our immunofluorescence results, Ninein staining showcased differential localization, indicating we are disrupting an aspect of Ninein function. This was also seen with the localization of other proteins known to interact with Ninein. Future studies will conduct electrophysiology experiments to measure GABAergic signaling and focus on RNA sequencing data to analyze differential expressions, alternative splicing, and further validate our knockout model.

Abstract Name: Designing for Bi-directional Trust in Agentic AI Systems: Design Patterns for Safe Human-Agent Teaming

As agentic AI systems gain popularity by operating with autonomy to execute decisions, the trust paradigm is dynamically changing from the unidirectional trust from human to machine into a model of bidirectional trust for successful collaboration. While existing work in Explainable AI (XAI) emphasizes transparency and user control, it largely fails to address the reciprocal dynamic in understanding how the agent can evaluate the reliability of human input and adapt its behavior to achieve mutual understanding. This paper addresses this gap by defining the functional interface design patterns necessary to calibrate bidirectional trust Through a qualitative study involving semi-structured interviews with 8 design professionals and students, four key findings emerged, highlighting that users currently view the agent as a productivity amplifier requiring constant supervision. Participants indicate that auditability and the ability to intervene are critical for delegation, and that iterative prompting serves as a signal of low human confidence that agents currently fail

to interpret. Based on these insights, we propose a Bidirectional Trust Design Framework as a set of design patterns. Based on these findings, we propose a Bidirectional Trust Design Framework built upon three core patterns: Audit & Trace (enabling logic scrutiny), Control & Override (establishing functional recovery), and Agent Confidence Check (empowering the agent to interpret human reliability). This research is significant to the HCI community as it shifts the discourse from static transparency to dynamic, mutual reliance. The proposed framework offers concrete, actionable design patterns to achieve necessary trust calibration, providing a framework for an agent to interpret the reliability of its human partner and enabling safe human-agent teaming.

Abstract Name: From Risk to Opportunity: The Paradoxical Link Between Alcohol Use and Colorectal Cancer Screening Among Older U.S. Adults

Alcohol consumption, particularly high-risk drinking behaviors, is assumed to impede engagement with preventive health services, like colorectal cancer screening (CRC). However, the relationship between alcohol use patterns (current and binge drinking) and CRC screening remains unclear, especially within diverse population subgroups. Thus, the objective of this study is to investigate the association between current and binge drinking and adherence to CRC screening guidelines among U.S. adults, and to examine how these relationships are influenced by sociodemographic, behavioral, and healthcare access factors. A cross-sectional analysis of 7,871 adults aged 45 and older using the 2023 Behavioral Risk Factor Surveillance System dataset was conducted. Multivariable logistic regression models assessed the associations between alcohol consumption patterns and CRC screening, adjusting for various factors. Effect modification by age and race/ethnicity was explored. Essentially, 6.4% of participants who underwent CRC screening were binge drinkers, while approximately 41% of the total population had undergone CRC screening. Multivariable analysis showed that binge drinking, physical activity, health insurance coverage, and depressive disorder were significantly associated with higher odds of CRC screening. In the stratified analysis across age groups, binge drinking and current drinking were positively associated with increased odds of undergoing CRC screening across all racial groups. Both binge and current alcohol use were independently associated with modestly increased odds of CRC screening, particularly pronounced among Hispanic adults (55–64) and White adults (65 and older). These results show that colorectal cancer screening is more common among those with higher education, income, insurance, and regular healthcare access. Leveraging these encounters with targeted outreach could help address ongoing gaps in CRC screening for underserved groups. Unexpectedly, current and binge drinking were modestly associated with increased screening rates among older Hispanic and White adults. This suggests that higher-risk individuals may have more opportunities for preventive care through increased system contact.

Abstract Name: Barriers to Postpartum Depression Treatment: Availability and Accessibility of Maternal Behavioral Health-Inclusive Support Groups for Low-Income Populations

The maternal health crisis is a prevalent and concerning issue in the United States. Along with socioeconomic status (SES), racial injustices, inadequate coverage, the lack of efficient availability and accessibility to health care services plays a significant role in augmenting this problem. One health care service that is often undernoted is maternal mental health care services, for prevalent issues like Postpartum Depression. Considering the socioeconomic burdens of low-income mothers, this paper analyzed the accessibility and availability of maternal health support groups across counties in Florida, with varying amounts of individuals below the federal poverty level (%BPL). Essentially, Florida counties were divided into one of four categories depending on their %BPL. A Fisher's Exact Test was performed to see if there was an association between the category type and the number of counties in it that provided support groups. The study then conducted a thematic analysis on the highest-%BPL and lowest-%BPL counties' support programs to study their accessibility to mothers, in terms of cost and transportation. A significant association ($P=0.0124$) was found between the category type and the availability of support groups in that region, with the proportion of support groups decreasing from counties with low %BPL (categories 1 and 2) to counties with high %BPL (categories 3 and 4). Additionally, transportation and cost options were limited or made unavailable, adding on to the burden for low SES mothers. This paper essentially found that apart from the mother's individual SES, the community she lives in can contribute to the burden of finding proper health care resources. Additionally, limited accessibility of certain programs can take away from the positive value added by its availability.

Abstract Name: Linguistic Indicators of Positive Emotion Predict Long-Term Eating Disorder Symptom Change

Disordered eating behaviors impact an estimated 10–20% of young women, yet access to care remains limited. Digital interventions, including chatbot-delivered programs, have gained popularity due to their accessibility and scalability, but further research is needed to clarify which user–chatbot interaction mechanisms predict treatment response. Because all interactions occur in text and language may reflect users' emotional states, this secondary analysis of a randomized controlled trial of a two-month, rule-based chatbot prevention program examined whether positive emotional language predicted longer-term changes in eating disorder symptoms. Accordingly, 199 young women ($M_{age} = 21.08$, $SD = 3.09$) at risk for eating disorders who were randomized to a chatbot intervention, completed at least one follow-up assessment, and had at least one interaction with the chatbot assessed. Participants self-reported eating disorder symptoms at baseline, three-month, and six-month follow-ups using the Eating Disorder Examination Questionnaire. User-authored messages were quantified using the National Research Council Emotion Lexicon to assess the degree to which participants expressed four positive emotions, joy, trust, anticipation, and surprise, during user–chatbot interactions and were combined into a composite index using principal component analysis. Linear mixed-

effects models tested whether positive emotional expression during the two-month prevention program predicted changes in eating disorder symptoms across the six-month follow-up. Participants who expressed more positive emotion language in user-chatbot interactions showed greater decreases in eating disorder symptoms from baseline to six-month follow-up ($b = -0.14$, $SE = 0.05$, $p = .007$, partial $\eta^2 = .04$). This association did not emerge at the 3-month follow-up. This pattern suggested that positive emotion language, and the emotional states it reflects, may signal later symptom improvement following chatbot-delivered prevention programs. Consequently, fostering such expression could potentially support longer-term symptom reduction. Future work should test whether positive language uniquely predicts improvement beyond other established predictors.

Abstract Name: Inhibition of Glutamine Metabolism is Essential in Decreasing the Hallmarks of Atopic Dermatitis Pathogenesis

Atopic Dermatitis (AD) remains one of the most chronic inflammatory skin diseases and is strongly associated with other atopic diseases like asthma. Although the Th2 response is known to be the primary humoral response in AD, follicular helper T (Tfh) cells have been recently identified as key mediators in AD pathogenesis. AD presents with increased serum IgE levels and associated cytokines, IL4 and IL13. Our lab has shown that upon stimulating dendritic cells with *Alternaria alternata* (a fungal allergen) in an allergic asthma model, there was an increase in the glutamine metabolic pathway. Upon inhibiting the glutamine metabolic pathway, we observed a reduction in downstream Tfh2 polarization and reduced IgE production. We therefore hypothesized that Telegnastat (CB-839), a glutaminase I inhibitor, would decrease Tfh2 responses in AD. Auricles of C57BL/6 mice were treated with MC903 and house dust mite for a period of 15 days. Ear thickness was measured throughout the model. Mice received topical treatment with CB-839 after day six. Mice were euthanized on day 15; organs were harvested and processed for flow cytometry, sectioning, and RNA isolation for gene expression analysis. Topical treatment with CB-839 inhibited AD in treated mice with a reduction in IgE+ and IgG1+ plasma cells as well as Tfh2 cells, while an increase in T follicular regulatory cells was observed. AD-associated genes such as GATA3 and CARD11 were observed to be decreased in CB-839-treated mice. Overall, topical treatment of AD with GLS-1 inhibitor, CB-839, in mice is associated with a decrease in the hallmarks of AD.

Abstract Name: A Parametric Investigation of Droplet Motion on Twisted Wires

Research was conducted on the effectiveness of bead-on-fiber systems for use in wet scrubbers, which

normally utilize liquid drops falling in air where drops fall at their terminal velocity. Prior research has shown that a drop falling down a fiber (a bead-on-fiber system) travels at a lower terminal velocity, enhancing the ability of a wet scrubber to remove particles from a gas. That prior work showed that though the liquid viscosity primarily determined the bead-on-fiber terminal velocity, the fiber geometry might also play a role. The goal of this research was to determine whether the use of twisted wires impacts the terminal velocity of a bead-on-fiber drop, demonstrating the potential for increased tuning of droplet motion by altering the fiber geometry. Silicon oils of a range of viscosities are tested flowing down vertical twisted wires with various diameters and twist densities in order to study primarily the relationship between these parameters and the drop velocity. The experimental setup allows the fluid to be pumped down a vertical wire and recorded with a high-speed camera; this, combined with a MATLAB script to identify and track the drops, allows several parameters to be measured, including the drop diameter and velocity. The results were then used to develop a more detailed picture of the bead fall velocity, which is affected by its contact with the wire and surrounding air. Ultimately, through the results of this and previous experiments, we developed an understanding of the relationship between the drop speed and the wire geometry and identify the optimal parameters for enhancing wet scrubber performance.

Abstract Name: Generalization of AI Fake News Detection Across Prompting Styles

AI-generated fake news can be produced under a wide range of prompting strategies, yet most detection models are trained under a single generation setting, raising concerns about their ability to generalize across unseen prompting styles. This study investigates whether machine learning models trained on AI-generated fake news produced using one prompting strategy maintain reliable detection performance when tested on AI-generated fake news produced under different, previously unseen prompts. Using real news, human-written fake news, and AI-generated fake news, detection models are trained under a fixed training prompt and evaluated under cross-prompt testing conditions. A structured feature representation capturing document length measures, sentence structure, lexical diversity, punctuation and capitalization usage, standard readability indices, and fine-grained sentiment and emotion scores is used for model training and evaluation. Multiple classifiers, including logistic regression, random forest, support vector machines, extreme gradient boosting, and a deep neural network, are evaluated under this cross-prompt generalization setting. Model performance is assessed using accuracy, area under the receiver operating characteristic curve, and precision-recall analysis, and performance degradation between within-prompt and cross-prompt testing is used to quantify generalization failure. This study evaluates whether detection performance changes when models are applied to AI-generated fake news produced under unseen prompting strategies and examines the extent of prompt sensitivity and potential distributional shift. This analysis informs the robustness of detection systems trained under limited generation conditions and supports the development of prompt-robust misinformation detection models that can better adapt to evolving AI generation behaviors.

Abstract Name: Multimodal Framework for Semantic Video Search

Traditional video search systems rely on manual tags or simple keywords, which often fail to capture the actual meaning of video content. Modern semantic search tools fix this problem but typically depend on expensive cloud services, raising issues around cost, privacy, and data control. This project presents a local, open-source video semantic search engine designed to overcome those limitations. Our system uses two key models: Whisper for accurate speech-to-text transcription and CLIP for extracting visual features from video frames. We combine these text and image representations into multimodal embeddings and store them in a local vector database. This allows users to search videos using natural language queries—for example, “a lecture about quantum mechanics” or “a car driving in the snow”—and receive precise, timestamped results. The project demonstrates that advanced semantic video retrieval can be achieved on standard hardware without relying on proprietary cloud APIs. By keeping all processing local, the system offers a cost-effective and privacy-preserving solution for universities, researchers, and organizations managing large video archives.

Abstract Name: Comparing Olivine Geochemistry From Two Volcanoes In Iceland To Understand Magma Sources

Recent volcanic episodes in the Reykjanes Peninsula of Iceland began in 2021 in Fagradalsfjall and are continuing today in Sundhnúkur. The two neighboring eruptions are similar in style (effusive lava flows). Observing basalt lava hand samples from both eruptions show the presence of magnesium-rich and iron-rich olivines in very close proximity. Preliminary differences in whole rock chemistry analyzed using Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES) show a higher average iron content from Sundhnúkur basalt and a higher average magnesium content in samples from Fagradalsfjall. Fagradalsfjall basalts have relatively larger olivine crystals than those from Sundhnúkur. Under a petrographic microscope, samples from Sundhnúkur basalt show large clusters of olivine, pyroxene, and plagioclase crystals. Olivine is the first mineral to form from cooling basaltic lava. The chemical and textural differences between olivine crystals in the lava from these volcanoes may indicate the location of the magma source and cooling history. Using data from Powder X-ray Diffraction (PXRD), ICP-OES, and textural analysis under a petrographic microscope, we can observe the differences between the olivine crystals in the same sample as well as differences in samples from Sundhnúkur and Fagradalsfjall. This poster will present data from hand samples, ICP-OES, and PXRD showing the differences between the basalt from the two volcanoes, along with an analysis of the olivine present in both.

Abstract Name: Who We Want, Why We Want Them: An Investigation of Mate Preferences Among Lesbian Women

One of the most important decisions people make is choosing a romantic partner. But how do people make these decisions, and what factors shape their preferences? Research in social psychology has provided some answers—particularly among heterosexual individuals. On average, heterosexual men tend to prefer short-term relationships with younger, physically attractive partners. In contrast, heterosexual women often seek long-term, committed relationships with partners who are older and financially stable (Kenrick & Keefe, 1992). However, less is known about whether these patterns apply across people of different sexual orientations. For example, studies suggest that gay men, like heterosexual men, are drawn to younger, attractive mates. But the preferences of lesbian women remain less clear and results are more inconsistent across studies (e.g., Bailey et al., 1994; Silverthorne & Quinsey, 2000; Conway et al., 2015). The present study aims to further explore these inconsistencies by conducting an online survey experiment investigating how different groups (heterosexual men, heterosexual women, homosexual men, and lesbian women) rate 16 excerpts of dating profiles in which targets vary in gender (man or woman), attractiveness (more attractive or less attractive), age (young or old, relative to participants), and status of their job (high or low). This work seeks to advance our understanding of people's attractiveness preferences in general, as well as contribute to our understanding of these preferences in non-heterosexual populations, who are often understudied in the research.

Abstract Name: Before Silicon: Charles Babbage and the Birth of Mechanical Computing

This study investigates how Charles Babbage's (1791–1871) designs of the Difference Engine and the Analytical Engine advanced nineteenth-century computational mathematics, while examining the social, financial, and technological barriers that prevented their completion during his lifetime. Babbage's designs have since become a focal point for historians tracing the origins of computational thought and the evolution of mechanical reasoning in the nineteenth century. Numerous scholars, including Doran Swade and Allan Bromley, have completed detailed research on Babbage's devices and have gone so far as to build one of his machines in the late 20th century to better ascertain the ingenuity of his work. Despite the technological limitations of the nineteenth century, Babbage's vision for mechanical calculators would have represented a revolutionary step toward automating mathematical calculations. Designed to automate the computation of polynomial functions, the Difference Engine would have significantly reduced human error in mathematical tables. In contrast, the Analytical Engine introduced core modern computer components such as the CPU, memory, and storage. Perhaps the most groundbreaking concept introduced by the Analytical Engine, however, was the idea of user programming, discovered by Babbage's contemporary, Ada Lovelace (1815–1852). Babbage's work serves as a window into the timeless tradeoff between the possibilities of new technologies with the constraints imposed by contemporary attitudes and costs. His work thus demonstrates that innovation is not always the sudden breakthrough of a single idea; rather, it is more often an evolutionary process dependent on inventions being both practical and affordable. Future research could examine how Ada Lovelace's early insights influenced the evolution of artificial intelligence.

Abstract Name: Stakeholder Interviews of Partners: Understanding the Impact of a Community Care HUB

Abstract: The Omaha Pathways HUB is an initiative of the Omaha Community Foundation. According to the Center of Excellence to Align Health and Social Care, a community care hub (CCH) “serves as a community-focused regional, statewide or multi-state umbrella organization that coordinates, centralizes and scales administrative functions and operational infrastructure on behalf of a network of community support providers”. The Omaha Pathways HUB focuses on maternal child health connecting pregnant women with a community health worker to help them navigate pregnancy and the post-partum experience. This initiative helps connect pregnant and postpartum people at elevated risk with coordinated health and social services. To inform ongoing evaluation and guide program growth, semi-structured interviews with participants and community health workers are being conducted. These interviews will be conducted through a process of audio recordings that were then transcribed, de-identified, and analyzed using a codebook developed by the lead evaluator with two trained student coders. The team will independently apply the codebook and come up with themes through team discussion. Themes and recommendations will be extracted for the purposes of program evaluation. The project is currently under approval by the Institutional Review Board and results will be shared at the conference.

Abstract Name: Photocatalysis of Organic Reactions Using Crude St. John's Wort

Natural products, like hypericin, have attracted interest as cost-effective, safer photocatalysts in organic synthesis. They effectively absorb light and offer an alternative to metal-based catalysts like ruthenium and iridium. Hypericin and its derivatives are naturally found in the supplement St. John's Wort, but isolating pure hypericin is difficult due to the low concentration. Although bioengineering microorganisms to produce hypericin is possible, it is technically complex. Instead, we explored using St. John's Wort supplement capsules directly as the photocatalyst in arylation reactions with diazonium salts and aromatic rings. Reaction conditions were optimized by purifying the capsules, using an everyday sun lightbulb, and irradiating for 48 hours. To evaluate the efficacy of this approach, the recyclability of the St. John's Wort will be tested using eco-friendly deep eutectic solvents and room temperature ionic liquids. The results of this research should highlight the potential for natural product mixtures to serve as effective and simple photocatalysts for organic reactions.

Abstract Name: Krüppel-Like Factor 4 Downregulates Fatty Acid Synthesis Related Genes Clara Vickery and Engda Hagos Department of Biology, Colgate University, Hamilton, NY, 13346, USA

KLF4 is a zinc-finger transcription factor involved in cellular processes such as cell proliferation, cell cycle regulation, differentiation, autophagy, and genomic stability. Prior work in our lab has indicated in the absence of KLF4, mitochondrial damage may facilitate a shift towards glycolytic metabolism, indicative of the Warburg effect. However, the role of KLF4 in lipid metabolism as a method of maintaining genomic integrity remains to be elucidated. Given that cancerous cells tend to upregulate levels of lipid metabolism to benefit off of by-products to proliferate and evade chemotherapies, we wanted to investigate the connection between KLF4 and lipid metabolism. This study seeks to address the role of KLF4 in lipid metabolism in both mouse embryonic fibroblasts (MEFs) and human colorectal cancer cells (RKOs). We specifically looked at key lipid biosynthesis enzymes acetyl-CoA carboxylase (ACC), fatty acid synthase (FASN), pyruvate kinase M2 (PKM2), and ATP citrate lyase (ACLY). When treated with 2-DG, a drug that inhibits glycolysis, cells lacking KLF4 upregulated FASN and PKM2, indicating the role for KLF4 as a tumor suppressor to downregulate the enzymes involved in lipid biosynthesis. Furthermore, cells treated with TOFA, an ACC inhibitor showed upregulation of lipogenesis and fatty acid oxidation enzymes FASN, PKM2, ACC, and ACLY. Next, in order to visualize intracellular lipid storage, we employed the use of Oil Red O staining and found that cells lacking KLF4 exhibited higher levels of lipid droplet accumulation. Finally, in order to determine cell viability, we conducted a Trypan Blue cell death assay. We found that cells containing KLF4 are more sensitive to glucose starvation and dying at higher rates as compared with cells lacking KLF4. Taken together, our findings provide a rationale for the impaired metabolism in cells-null for KLF4 and how KLF4 regulates various metabolic enzymes to maintain metabolism homeostasis and genomic stability.

Abstract Name: Depicting Diversity in Dentistry: Analyzing Racial, Gendered, and Ethnic Representation in Textbooks

This project examines representation of human variation in dental education materials, specifically within textbooks published from the early twentieth century to the present. The field of dentistry continues to reflect major inequities, including the severe underrepresentation of Black dentists within the profession. These disparities coexist with persistent gaps in oral-health outcomes, which includes higher rates of edentulism and delayed diagnoses of disease in marginalized communities, making it essential in understanding how educational materials contribute to these patterns. The central research question asks: How are racial, gendered, and ethnic diversity portrayed in visual and written content within dental textbooks? To answer this, we selected textbooks from different areas of dental education (e.g. dental anatomy, general dentistry), then systematically abstracted visual and written information on features including oral health, oral pathologies, and patient/provider characteristics including skin melanation, gum melanation, hair color, gender performance, and other features. We completed a textual analysis to identify how dental textbooks portrayed racial, ethnic, and gender normativity and non-normativity among patients, providers, and oral pathology. Preliminary findings reveal a severe underrepresentation of minority patients and clinicians, with depictions primarily reflecting light-pink gingival tissue and predominantly white, male providers. This lack

of visual and textual diversity indicates that dental students are trained with a limited understanding of normal variation in oral presentation and clinical relationships. These may partially explain dentistry's slowness to diversify, especially relative to other health professions, and, may contribute to implicit biases in diagnosis and treatment. By applying these findings within the broader context of systemic inequities in healthcare and education, the project seeks to highlight the urgent need for inclusive reform. Ultimately, this research emphasizes how more representative educational materials can contribute to a dental workforce more representative of the U.S. demographic makeup, improved outcomes, and a more equitable standard of care for all patients.

Abstract Name: Aging and Alzheimer's Disease Impair Vascular BKCa Channel Function

Large-conductance calcium-activated potassium (BKCa) channels help regulate the cerebral vascular tone by responding to localized calcium signals in vascular smooth muscle cells (VSMCs). These channels are activated by calcium sparks that originate from lysosome-dependent calcium release and sarcoplasmic reticulum stores. BKCa function can also be altered by oxidative post-translational modifications that change channel gating. Aging and Alzheimer's disease (AD) have both been associated with reduced BKCa activity, but it is unclear whether similar upstream mechanisms contribute to this dysfunction in each condition. This project examines lysosomal acidity and BKCa channel function in VSMCs from aged wild-type mice, 5x-FAD mice, and adult healthy controls using lysosomal imaging and patch clamp electrophysiology. Cerebral VSMCs were freshly-isolated and all experiments were performed on these isolated cells. Lysosomal acidity

imaging was performed using a pH-sensitive dye that accumulates in the lumen of lysosomes. VSMCs from aged and 5x-FAD mice showed decreased lysosomal acidity relative to healthy adults, which was recovered with EN6, a lysosome acidifier. Reduced acidity can decrease calcium release from lysosomes and alter calcium signaling dynamics in VSMCs. Thus, we used perforated patch clamp to address this possibility, a technique that maintains intracellular signaling. We observed reduced BKCa currents in both aged and 5x-FAD mice compared to healthy adult controls; both were recovered with EN6. Single-channel inside-out recordings measured BKCa open probability in response to calcium alone and calcium plus dithiothreitol (DTT), a reducing agent that can reverse certain oxidative modifications. In aged mice, DTT partially restored BKCa activity, suggesting the presence of reversible oxidative modifications. Together, these findings suggest that impaired lysosomal acidity and oxidative modifications may both contribute to reduced BKCa function in aging and AD. Ongoing work will further compare BKCa impairment in 5x-FAD mice to clarify whether aging and AD involve similar upstream mechanisms influencing cerebrovascular dysregulation.

Abstract Name: Optimizing Specificity of Fluorogenic Carbonates for Human Carboxylesterase 1

Carboxylesterase 1 (CES1) is a serine hydrolase that plays a vital role in metabolism of many drugs. Despite this established role, CES1 remains understudied compared to other drug metabolic enzymes. To address this, we are interested in making fluorogenic chemical tools that can report on the activity of CES1 in living cells. Recently, our group developed a fluorescein-based carbonate as a CES1-specific fluorogenic chemical tool. This project focuses on optimizing the carbonate substrate for enhanced CES1-specificity. Following synthesis of 11 fluorescein-based carbonates, we evaluated their stability in solution and determined their specificity for CES1 and CES2 in vitro. Our results indicate that a few carbonates may be more specific for CES1 over CES2 than our existing substrate. After determining that these carbonates are suitable for use in live cells, we are now evaluating their specificity. The more specific fluorogenic chemical tools we develop in this study will aid in creating a better understanding of CES1's role in drug metabolism enhancing human health.

Abstract Name: Jamie Reid: Anarchist of the British people

During the 1970s, Britain was facing deep economic struggles, inflation was high, the unemployment rate was rising and the people were doubting the monarchy. Out of everything going on during these times, a specific theme stuck out, Punk. It was a raw cultural response to society that was in utter chaos. Punk wasn't just about sound or style; it was a way of rebellion. At the center of punk's identity stood Jamie Reid, a

designer who turned that rebellion into art. Reid was not only creating graphic design for the Sex Pistols, He was using his visual styling of punk to create a weapon to attack the monarchs in Britain. From his use in ransom - note typography, and provocative imagery gave the people who were voiceless a way of protest. Reid's background in political art and his connections to Situationist ideals shaped his belief that design could challenge authority rather than be a serving tool. Throughout his work one of the most influential was his work with the Sex Pistols, he transformed graphic design into a form of protest that was able to attack the monarchy, capitalism and fake promises made by the mainstream media. His work wasn't made to define punk - it was to prove that design could be more than just logos and branding. He wanted to express a communication that wasn't just for the Man but for the peoples voices who were left unheard.

Abstract Name: A Personal Reason for Theistic Belief: Epistemic Trust, Proper Functionalism, and An Awareness of Persons

In philosophy, a belief is either rational or irrational. Since the end of the medieval period, the view that belief in God is irrational has grown to be ubiquitous. In my research, I have focused on whether it is or isn't. I argue that for belief in God, especially the kind where God is a person of some sort, it is rational to believe based on the testimony of others that God exists. This is so because we're more than ready and would never think twice to believe that (1) we have met at least one other person and/or (2) that others have also met at least one other person. If this is the case, then we should not doubt when others tell us that they have met or encountered God in their lives. I also exploit the popular, implicit assumption that if all the people we have encountered are human, all people must be human. Though it is similar in many respects to other views in philosophy, it is a novel view which combines several elements of philosophical inquiry: trust, testimony, personhood, and properly working faculties. Throughout the research and writing process, I have studied formal logic and have read many works of epistemology and the philosophy of religion. This project is quite important to me, as it has been my conviction, even before my belief that there is a God, that all should strive to be rational people. I believe that this research promotes rationality amongst believers and non-believers of God alike; but I also hope that it unites scholars and intellectuals of these kinds in the academy.

Abstract Name: Investigating the Therapeutic Potential of Dose-Dependent Cannabinoids in Repairing β -Oxidation in MASLD

Metabolic dysfunction associated steatotic liver disease (MASLD) is the leading chronic liver disease globally with incidence rates on the rise. MASLD is diagnosed when there is a $\geq 5\%$ build up of lipids in the hepatocytes and is not associated with high alcohol consumption. MASLD is closely linked to insulin resistance (IR). IR can impair β -oxidation resulting in MASLD due to the insufficient conversion of FA to

acetyl-CoA to generate ATP, thus leading to decreased lipid droplet breakdown. Moreover, the body upregulates β -oxidation in order to compensate for excess FA, though this can result in reactive oxygen species, highlighting the need for metabolic balance. Currently, there are no pharmacological treatments for MASLD. Cannabinoids come from *Cannabis sativa* and have increasing popularity from a pharmaceutical lens. Two major cannabinoids are cannabigerol (CBG) and cannabidiol (CBD). CBG has shown anti-inflammatory and agonist properties. CBD has also shown anti-inflammatory properties and is used to treat neurological disorders. However, the effects of these cannabinoids on β -oxidation is still unclear, therefore, the purpose of this research is to determine if CBG and/or CBD can restore normal β -oxidation in relation to alleviating MASLD. 8 week old male and female mice (n=32) were randomly assigned to control (CTRL) (n= 8) or high-fat, high-fructose diet group (HFD) (n= 24) for 16 weeks. At week 8, HFD mice were subdivided into HFD, HFD+CBG, and HFD+CBD groups, supplemented with 1.23 μ g/day of CBG or CBD via gummy. In week 17, mice were sacrificed and livers were harvested. Mitochondrial function was assessed using the Seahorse XF Cell Mito Stress Test. Lipid accumulation was evaluated via Oil Red O staining in MASH liver tissue. Detection of β -oxidation via western blot was observed using CPT-1 and PPAR α antibodies and densitometry using ImageJ and statistical analysis via GraphPad Prism.

Abstract Name: Breaking the Ice: Assessing Films as an Introduction to Asian Culture at Southwest Texas College

Southwest Texas College (SWTX) in Uvalde, TX is an institution with predominantly high numbers of Hispanic students. With three main campuses in the southwest region of Texas, the Hispanic enrollment rate reached 91% in 2025, with a recorded student population of 1% of Asian descent. At a social level, lack of cultural differentiation correlates with low cultural knowledge, low multicultural competence, and poor educational experiences. At a personal level, a lack of cultural heterogeneity correlates with low self-awareness, low cognitive skills, and decreased scholarship. A survey conducted at SWTX showed that only 25% of students were able to locate China, The Republic of Korea, and Japan correctly on a world map, whereas 35% were incapable of locating any. In an attempt to recognize a means of introducing Asian culture, a small student group completed film analyses of films that crossed over cultural borders. The films were selected for a variety of reasons: critical acclaim, commercial performance, and award-winning status. Each of these films stemmed from the countries listed above were assessed for their ability to introduce Asian customary knowledge to an otherwise deficient student community. Additionally, interviews were conducted

with natives and descendants of the respective countries and presented with data compiled from the film analyses to determine the quality of the cultural knowledge attained. Preliminary analysis of the data compiled and assessed for accuracy between cultural presentation in film and the experiences of the interviewees suggest the usefulness of film as an introductory means to cultural knowledge attainment.

Abstract Name: Environmental exposures in neurodegenerative disease: Effects of copper on post-translational histone modification levels in *S. cerevisiae* ALS/FTD models

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease associated with motor neuron deterioration and loss of voluntary muscle movement. ALS forms a disease continuum with frontotemporal dementia (FTD), which is connected to the death of neuronal cells in the frontal lobe of the brain. Interestingly, exposure to environmental toxins - including heavy metals like copper - has been linked to an increased risk of ALS. In fact, an elevated level of copper has been observed in neuronal matter of ALS patients, potentially causing copper toxicity connecting to the protein aggregation present in ALS. We and others have revealed that ALS/FTD is associated with certain epigenetic changes, including changes on the post-translational modification profile of the DNA-packaging histone proteins. The addition of chemical groups on histone tails, like methylation and phosphorylation, can impact gene expression. However, the exact post-translational histone modifications affecting ALS/FTD is still not certain. We hypothesized that copper exposure may impact the post-translational histone modification landscape in yeast. We treated *S. cerevisiae* with different concentrations of copper chloride and measured the changes of post-translational histone modifications through Western Blotting. Upon treatment with copper, we found an increase in the levels of H3S10ph and H3K14ac with decreases in H3K36me3. Meanwhile, the levels of H3K79me3 and H3K27ac remained unchanged. Some of these changes mirror those observed in overexpression models for neurodegenerative disease proteinopathies, such as TDP43 and PR50. For instance, decreases in H3K36me3 are connected to TDP43 toxicity while increases in H3S10ph are linked to the PR50 proteinopathy. These changes in the levels of histone modifications can potentially reveal connections between environmental exposures, protein aggregation and cell death associated with ALS/FTD and neurodegeneration. Such connections can be used to find treatments for these neurodegenerative diseases that target their mechanistic pathologies.

Abstract Name: Ways of Rhetoric, Ways of Life: Persuasion and Performance in the Language of Poets and Lawyers

This project explores the central question: how does rhetoric function as a shared mechanism of persuasion between poetry and law? Both poets and lawyers rely on language to shape perception, evoke emotion, and argue for truth, whether in the courtroom or on the page. Through a comparative rhetorical analysis, this research seeks to uncover how these disciplines converge in their use of argumentation, performance, and audience engagement. Drawing on primary texts such as Layli Long Soldier's *Whereas*, Amanda Gorman's "The Hill We Climb," and Johnnie Cochran's closing argument in the O.J. Simpson trial, the study will analyze rhetorical devices including repetition, syntax, humor, rhyme, and metaphor—the latter serving as a critical bridge between poetic and legal persuasion. The theoretical foundation will incorporate Aristotle's Five Canons of Rhetoric and scholarly works by Kenneth Burke, S.W. DeLong, Louise Rosenblatt, and James Boyd White. Methodologically, the project employs close reading and viewing, with rhetorical analysis to compare legal and poetic texts, both written and bodily performed forms of discourse. This interdisciplinary approach aims to reveal how each practice uses language as a performance of ethos (character), pathos (emotion), and logos (reason). The expected outcome is a demonstration that rhetorical awareness not only binds poets and lawyers in their persuasive endeavors but also deepens our understanding of language as an instrument of justice, art, and human connection.

Abstract Name: Developing In Silico Models of Breast Tumor Tissue to Assess Biomechanics of Tumor Microenvironment

The differences and interactions between cancerous and noncancerous tissues within breast tumor microenvironments present numerous obstacles to research, varying case by case and dependent on location. The current study aimed to develop in-silico models of patient-specific breast tumor tissue which will then be applied to assess the tumor's malignancy through quantifying the forces within the breast tumor tissues. We used the standard and high-definition Fourier Transform Infrared (FTIR) imaging to image and classify forty tissues to four distinct breast tissue pathology types: "Normal Breast Tissue," "Hyperplasia," "Invasive Carcinoma of No Special Type," and "Invasive Lobular Carcinoma." Using an FTIR imaging microscope, we will first record high-definition data and apply numerical noise reduction methods to provide high spectral signal-to-noise ratio. Standard definition data then will be recorded on the same breast tissue samples. The FTIR images were received in MATLAB file format and processed to extract six individual tissue components present in each sample: malignant epithelium, noncancerous epithelium, dense stroma, loose stroma, reactive stroma, and other (e.g., blood vessels, inflammatory cells). In total, 101 FTIR files were processed. The extracted tissues were segmented in MIMICS to generate two-dimensional STL representations of each tissue type. To obtain the quantity of each tissue type present in each sample, MATLAB was used to calculate the surface area of STLs exported from MIMICS. Ongoing study focuses on developing three-dimensional, particle based, in-silico models of breast tumor tissue by leveraging patient-specific data using the segmented image files exported from MIMICS into LAMMPS (Large-scale Molecular Dynamics Massively Parallel Simulator). Because mechanical properties of breast tissue are hallmarks for cancer initiation and progression, our models aim to quantify the von Mises stress distribution within the tissues. This study plays a critical role in developing targeted interventions and advancing our understanding of the biomechanical factors influencing cancer progression.

Abstract Name: Yarkovsky Effect for Particles in Circumlunar Space

The concept of Kessler Syndrome concerns the eventuality that increasing amounts of “space junk” in orbit around Earth will inhibit our ability to safely launch spacecraft from the surface of the planet into orbit and/or deep space. While countermeasures are slowly being taken for Earth, this is still an issue that persists for other celestial bodies. One solution that shows promise for solving this problem is utilization of the Yarkovsky Effect, which theorizes that objects in orbit are perturbed by photons as a result of illumination from sunlight. Our goal in this study is to review the feasibility of applying this in conditions that are void of atmospheric drag and perturbed by solar activity such as The Moon. From our review of the available literature on this hypothesis, we show that the default effect on space debris orbiting Earth is miniscule, but a shift in the semi-major axis of any given piece of debris can be altered by changing the spin axis with respect to the Sun. Another caveat of this theory is that timescales for such perturbations must be large due to the slow rate at which orbits may shift when this technique is utilized. However, in the absence of atmospheric drag, we theorize that Yarkovsky effect is more predominant among possible sinking and decaying mechanisms. Through our investigation, we aim to explain why spherical bodies may be less impacted by the Yarkovsky Effect compared to uneven surfaces. The data referenced from studies are all Earth based data. In the future, we plan to investigate how the impact of the Yarkovsky Effect varies for different materials (in addition to different shapes and roughness); with this research, we hope to provide insights into finding a solution for Kessler Syndrome via the intersection of orbital dynamics and materials science.

Abstract Name: Adsorptive Cathodic Stripping Analysis of Xylazine Within Fouling-Resistant and Nanomaterial-Enhanced Modified Electrode Sensors

Xylazine (XYL), an FDA-approved veterinary tranquilizer, is being abused both as an opioid adulterant in a street drug known as “Tranq-dope” and as a date rape drug. Given its now nearly ubiquitous use with fentanyl and fentanyl derivatives across the globe, XYL has become a primary target for researchers seeking to develop portable and cost-effective sensors for its detection. Electrochemical sensors based on the oxidation of XYL, while useful, have limitations due to certain interferents and inherent electrode fouling that render the approach less reliable, especially in certain sample matrices. In this work, modified electrode platforms incorporating layers of multi-walled carbon nanotubes for sensitivity, along with semi-permeable polyurethane (PU) layers and host–guest chemistry using β -cyclodextrin for selectivity, are deployed for XYL

detection using complementary adsorptive cathodic stripping analysis. The modified electrode sensors are optimized to minimize high potentials and maintain fouling-resistant capabilities, and investigated to better understand the function of the PU layer. The use of adsorptive cathodic stripping differential pulse voltammetry indirectly indicates the presence and concentration of XYL within complex sample media (beverages and synthetic urine). When used in this manner, the modified electrodes exhibited an overall average sensitivity of $\sim 35 (\pm 9)$ nA/ μ M toward XYL with a limit of quantification of < 10 ppm, while also offering adaptability for the analysis of XYL in different types of samples. By expanding the capability of these XYL sensors, this study represents another facet of tool development for use by medical professionals, first-responders, forensic investigators, and drug users to limit exposure and help stem the dangerous and illegal use of XYL.

Abstract Name: Design and Synthesis of Potential Antimicrobial Drugs

Microbial infections are some of the leading causes of death in the population at large, and antimicrobial-resistant “superbugs” have become a growing issue, so there is a great need to explore new and alternative pathways for fighting these diseases. One method for doing this is by exploring Methionine synthase (MetSyn), which plays a critical role in cellular one-carbon metabolism, catalyzing the methylation of homocysteine to form methionine, an essential amino acid required for protein synthesis and methyl group transfer reactions. Key differences between the B12-independent fungal MetSyn enzyme and the B12-dependant mammalian form can allow for selective targeting of the fungal enzyme. Inhibition of MetSyn disrupts central metabolic pathways and offers a promising strategy for therapeutic and antimicrobial development. One focus of this research is the design, synthesis, and evaluation of a novel inhibitor selective for cobalamin-independent MetSyn. Computational modeling and molecular docking were used to guide structural optimization of lead compounds. This interdisciplinary approach, integrating computational chemistry, organic synthesis, and quantitative chemistry, aims to elucidate the structure-activity relationships governing MetSyn inhibition. Another avenue for developing new antimicrobial drugs relies on plant-derived phytochemicals for plants with ties to traditional medicine. We have been exploring berberine, which we initially isolated from the *Argemone mexicana* plant. Numerous structural derivatives of berberine have been prepared in our lab, with many showing significantly improved antimicrobial effects, and greater microbial selectivity. Ultimately, the findings of this project will contribute to the broader understanding of drug design and may support the development of new antimicrobial agents.

Abstract Name: Integrating AI-Based Photogrammetry to aid Custom Pediatric Prosthetic Socket

Development

Rejection rates for upper limb myoelectric prostheses remain high at upwards of 35%. The prosthetic socket, serving as the primary interface between the patient's residual limb and their prosthesis, is a key contributor to device abandonment due to uncomfortable fittings. Conventional socket designs often fail to account for the complex geometry of residual limbs. Utilizing photogrammetry may provide an alternative method to generate accurate 3D limb models to serve as the basis for personalized sockets. Photogrammetry determines an object's dimensions and shape by analyzing images taken from multiple viewpoints, using geometry to calculate camera orientation and object coordinates. Previous research has demonstrated photogrammetry's feasibility in socket design workflows to digitize socket interiors and to model patient residual limbs via smartphone scanning. Compared to other modeling techniques, photogrammetry offers a cost-effective and accessible alternative for generating high-resolution 3D models. This research introduces the design of a low-cost, automated photogrammetric enclosure that enables 360-degree capture of a patient's residual limb instantaneously. The setup includes 28 Raspberry Pi Camera Modules, arranged in seven clusters of four cameras each, managed by seven Raspberry Pi 3B+ microcontrollers. A central Raspberry Pi 5 coordinates all image capture. A Python script executed on the Pi 5 signals each Pi 3B+ to capture and return images from its cameras. The resulting 28-image set is then processed using Apple's RealityKit API, which integrates artificial intelligence (computer vision algorithms) to construct a high-fidelity 3D model of the limb. This automated workflow shows promise to substantially automate the modeling procedures while reducing errors during image acquisition. Once the model is complete, a custom socket interface is generated procedurally; this offers a faster, reproducible, and more comfortable alternative to traditional manual methods.

Abstract Name: Predicting Applicant Acceptance of AI in Hiring

Organizations are increasingly using artificial intelligence (AI) in hiring processes, such as sourcing candidates, screening résumés, and analyzing interviews. We anticipated that applicants might feel concerned about this trend, so the present study examined what people know and believe about AI and how these views shape their reactions to AI-assisted hiring decisions. Sixty-three adults completed a survey measuring their familiarity with AI, perceived effectiveness of AI, and perceptions of AI's usefulness and ease of use in hiring. We also assessed their views of the procedural and interactional fairness of AI. Afterward, participants read a scenario in which an AI system contributed to a hiring decision that resulted in their rejection. All responses were rated on a 1 (strongly disagree) to 7 (strongly agree) scale. Correlational analyses showed that several factors predicted more acceptance of the negative hiring decision. Participants who were more familiar with AI ($r = .40$), who viewed AI as more effective ($r = .78$), more useful or easy to use ($r = .82$), or as procedurally ($r = .78$) and interactionally fair ($r = .68$) were more likely to accept the decision ($ps < .05$). The study is limited by its small sample size and potential measurement issues, particularly item wording. Future research should replicate these findings with stronger measures and consider experimental designs to clarify causal relationships. The results suggest that organizations may foster more positive applicant reactions by using AI tools that are fair, user-friendly, and clearly improve hiring quality. Educational institutions may also help by increasing familiarity with ethical and effective AI practices. Understanding these predictors can assist organizations in addressing applicant concerns about AI-driven hiring.

Abstract Name: Reconstruction in the North Carolina Piedmont

Reconstruction (1865-mid to late 1870s) was a time of great change and violence for the former Confederacy. Into this chaos, millions of formerly enslaved people tried to create freedom and new lives out of emancipation. They enjoyed newly won political, social, and economic freedoms across the South, but were met with hate and violence by many in the white community who sought to reestablish white supremacist rule across the South. White violence was extreme in North Carolina, where many historians have studied the Kirk-Holden War of 1870, when the state government repressed the Klan in Alamance and Caswell Counties. My research, instead, emphasizes the effects of the Kirk-Holden War on Black laborers on the North Carolina Railroad. In North Carolina, the Klan intimidated, attacked, and murdered Black freed people and white Republican allies as a means of suppressing Black organizing, social life, and enjoyment of civil and political rights across the Piedmont. After Governor William Holden called out the militia to suppress the Klan, white Conservatives took control of the State Government and impeached him, reestablishing white supremacist rule across the state. Even though they no longer had formal state protection, Black people, in particular Black railroad workers, carved out bits of freedom from this hostile system during the 1870s. Unlike sharecroppers, railroad workers had cash wages in a cash-poor South that enabled their families to send their children to school and for wives to choose to work for themselves and their families instead of for white people. This self-determination highlights the economic independence and security that these railroad workers gained from their labor, which enabled them to survive in a hostile white supremacist environment.

Abstract Name: Understanding Interactions of PFAS with DNA: A Potential Tool for Sustainable Degradation

Per- and Polyfluoroalkyl substances (PFAS) are known for their persistence and bioaccumulation within humans, wildlife, and the environment, earning the title “forever chemicals”. Previous research on PFAS removal includes graphene, active charcoal, and numerous other techniques, whereas degradation of such chemicals is still underexplored. The UV/sulfite system has been considered one of the best working models of PFAS degradation via aqueous electron generation, but this process involves 254 nm UV light, which is toxic as well as not scalable. Our research broadly focuses on a sustainable degradation method of PFAS at UV 365 nm which is available in sunlight. We hypothesize such degradation can potentially be facilitated by DNA, which allows us to study the interaction of DNA with PFAS chemicals. DNA has previously been reported as a biosensor (aptasensor) for PFAS, showing successful binding of DNA to perfluorooctanoic acid (PFOA). We have studied interactions of small strand DNAs with PFAS materials at both 365 nm and 254 nm to better understand the effect on degradation of PFAS using the UV/sulfite system in water.

Abstract Name: Investigating the neurodevelopmental effects of PFAS mixtures in a chicken embryo model

Per- and polyfluoroalkyl substances (PFAS) are a diverse group of synthetic compounds widely used in industrial and consumer products. Their strong carbon-fluorine bonds make them extremely resistant to breaking down, leading to environmental persistence, bioaccumulation, and both human and environmental health risks. Research has shown that early life exposure to PFAS compounds in humans can affect growth and development. While this is compelling, these studies have primarily been done in individual compounds, rather than PFAS mixtures, even though organisms are almost always exposed to these toxicants in combination. This study investigates the developmental effects of PFAS mixtures on chicken embryos, a model system with early developmental processes that are comparable to those of humans. Mixtures of five compounds (PFOA, PFOS, PFBA, PFBS, or PFHxS) were injected into fertilized eggs at an environmentally relevant range of concentrations, ranging from 100nM to 100µM. After 48 hours, embryos were then dissected and neural tube sections explanted. Neural crest cells were analyzed the following day using fluorescence microscopy to quantify cell death and mitochondrial quantity. Cell health was evaluated using Sytox Green live/dead staining, MitoTracker fluorescent dye was used for labeling for mitochondrial density, and NucBlue for visualizing the nuclei. Early results indicate that higher PFAS doses result in changes in development, reduced cell survival, and changes in mitochondrial abundance and quantity, with these effects increasing with the dose. These findings suggest that even relatively low PFAS mixture exposures can negatively affect development. Understanding how PFAS mixtures impact development is important for protecting environmental and human health. This research adds to the growing evidence that realistic, everyday levels of PFAS exposure may be harmful, highlighting the need for stronger policies that address PFAS mixtures rather than individual compounds.

Abstract Name: PECS: A Sustainable Model for Near-Peer Mentorship in Bolstering Postsecondary Education Enrollment

Around 67% of Virginia high school graduates enroll in institutions of postsecondary education. The Richmond Public School System, however, is reduced, at a rate of just around 54%. These disparities are indicative of larger trends in educational inequity: lower-income, minority students have higher dropout rates and attend schools that receive lower state funding, altogether leaving students inadequately prepared for higher education. While previous models have called for mentorship programs as a solution to these inequities, these programs often struggle to maintain participation and engagement. Personalized Exploration for College Success (PECS), a student-led 501(c)(3) nonprofit sponsored by the Virginia Commonwealth University Honors College, was created to address these disparities and to help students approach the college and scholarship application process with high-quality guidance, comprehensive resources, and a peer-driven support network. PECS employs a near-peer model, pairing high school students with mentors close in age. This model facilitates more effective engagement from high school students and draws on mentors' recent firsthand experiences navigating the college process. Through partnerships with two local school districts

(spanning eight high schools), the organization works to close opportunity gaps by providing individualized support, skill-building workshops, and accessible college application resources tailored to students' needs. Since its inception, PECS has engaged over 200 undergraduate students to volunteer in impactful ways, form close connections with younger students, and collaborate at a high level with University and high school district administrators. Participating high school students improve not only the quality of their college essays but also their motivation and autonomy, increasing student confidence and enthusiasm surrounding the college application process. The success of our program shows that, by connecting mentorship to real-world challenges, programs following the PECS model can empower every student – regardless of background – to engage and thrive in higher education.

Abstract Name: Exploring Participant Experiences in a Community-Based Prescription Produce Program: A Qualitative Analysis

Since 2016, the Virginia Commonwealth University School of Nursing and its community partners have collaborated to address persistent food and nutrition insecurity among older adults and individuals with disabilities living in federally subsidized housing across Richmond's urban food deserts. Over time, this collaboration has grown into the Mobile Health and Wellness Program (MHWP) and its signature Prescription Produce Program (PPP), a community-driven Food-is-Medicine model designed to expand access to fresh foods, strengthen social connectedness, and improve health outcomes. Previous scholarship focused on (1) early screening efforts that identified high rates of food insecurity and facilitated referrals to CSFP, SNAP, and local food assistance programs; (2) grassroots organizing with food justice partners to launch a community-led Healthy Meal Program; and (3) implementation of an innovative PPP that trains the next generation of health professionals. Despite these programmatic successes, a critical gap remains: little is known about the lived experience of individuals who participate in the PPP. Understanding how participants interpret program components, navigate social and structural barriers, and integrate PPP guidance into their daily lives is essential for strengthening program delivery and informing future interventions targeted toward marginalized older adult populations. The purpose of this project is to conduct a qualitative thematic analysis of 2023 PPP participant data to understand their experience of participating in a Food-Is-Medicine program. Findings will inform ongoing refinement of the PPP and contribute to the broader evidence base in interdisciplinary aging research.

Abstract Name: Empowering Future Nurses: The Importance of Advance Care Planning Education Through a Facilitation Event

Background: During Health Care Decisions Day, we held an Advance Care Planning (ACP) facilitation event. Event topics and instructional strategies reflected a literature review that highlighted the benefits that these events can have in increasing confidence in leading end of life discussions among nursing students (NSs), registered nurses (RNs), and nurse practitioners (NPs). Methods: The event included a keynote presentation on ACP, informational handouts on how to conduct ACP discussions, and a simulated end-of-life conversation using varied scenarios. To evaluate the effectiveness of the event, we used a pre- and post-survey to measure differences in knowledge and confidence between the two measurement times using the Mann-Whitney U test ($p < .05$). The pre-/post-survey was developed to measure educational content. Results: Significant differences were found in answers to seven survey questions. Participants reported increased familiarity with advance care planning ($p < .05$), greater confidence in facilitating ACP discussions ($p < .001$), and enhanced comfort with effective communication skills ($p < .001$). Additional gains were seen in confidence and ability to assist individuals in selecting and preparing a healthcare agent ($p < .001$), understanding of cultural and spiritual influences on decision-making ($p < .05$), perceived importance of ACP facilitation skills ($p < .05$), and preparedness for engaging in end-of-life conversations with patients ($p < .05$). Conclusions: This event highlighted the effectiveness of this educational method. Future researchers could replicate this event to support learning among health care students about ACP. ACP continues to be an underutilized resource for community members in clarifying goals of care. Enhancing healthcare students' familiarity, confidence, and communication skills can lead to improved patient and family experiences surrounding end-of-life conversations.

Abstract Name: Characteristics of Human, Pet and Deer Contact Captured on Social Media and Implications for Zoonotic Disease Transmission, 2015-2025

Increasing urbanization has led to more frequent interactions among humans, deer, and pets, raising concerns about the risk and emergence of zoonotic diseases. This highlights a need to monitor behaviors associated with disease transmission. Social media platforms offer an opportunity to collect data and identify emerging trends in human-wildlife contact. However, their potential remains underutilized, as few systematic approaches exist to effectively collect and analyze this data. Using an adapted systematic literature review protocol, videos posted on Facebook, TikTok, and Instagram from 2015-2025 that met the inclusion criteria ($n=1182$) were collected and reviewed. Extracted data included contact type, demographics, personal protective equipment (PPE) use, presence of pets, and metadata (season, number of likes, and location). Results show that the TikTok videos collected have the most likes and shortest duration. Most of the videos

were recorded in the spring and summer during the daytime. The highest rates of geotagged videos per 100k population were in Montana, Alaska, and Wyoming. The demographic distributions of the video's recorders were 90.3% white, 55.4% female, and 96.2% middle-aged (18-64 years old). 25.0% (n=295) of videos included a pet where 84.1% (n=248) of these included an interaction between the pet and deer. The most common contact types of deer/human were observing only (55.8%, n=660), touching/scratching/petting (37.5%, n=443), hand-feeding (13.3%, n=158), and rescuing (9.1%, n=108). Only 3.24% (n=38) of videos included PPE use. This protocol provides a valuable framework for researchers seeking to systematically use social media data to study human-animal interactions. The behaviors identified through this approach underscore significant public health concerns regarding zoonotic disease transmission, animal welfare, and injury risks. Furthermore, the role of domestic animals as potential intermediaries in disease transmission is an avenue for further examination. Overall, targeted interventions are needed to mitigate health risks associated with increased interactions.

Abstract Name: (Dis)enchanted Islands: Dubious Commemoration and Questions of Culture in the Jewel of Ecuador

My research focuses on the human history of Isla Isabela, Galápagos, Ecuador, specifically the public and social memory of the penal colony. After the Americans left their World War II military base on the Island, the Ecuadorian government created a penal colony. This colony, which lasted from 1946 to 1959, treated its prisoners very inhumanely, like by forcing them to construct El Muro de las Lágrimas (Wall of Tears): a stone wall that they were forced to build, deconstruct, and rebuild. After the 1958 prisoner escape, the Ecuadorian government closed the penal colony and formed the Parque Nacional Galápagos (Galápagos National Park). The legacy of the penal colony has only lasted in the social memory: the memories of witnesses, their descendants, and others who have heard the stories. My research explores four relevant themes to public and social memory theories. First, I explain the contradictions in information regarding the history and memory from my sources, including: 16 interviews, experiences, and texts. Second, I investigate how tourism is central to Galapagueñan life and how the role of the Muro (Wall) as a tourist site has created tension in this dark history. Third, I describe how after a history of conflict and stereotypes, there is still an everyday impact of the penal colony on the people. Finally, I explore the lack of commemoration or official history due to the official focus in natural sciences. This impacts the people, as they lack a commemorated history with which to construct a culture Isabeleña. Without a culture, the society risks a collapse of connection or integration. Above all, my research addresses the memory and effects of the penal colony in Isabeleña society today – a unique contribution to the field as my work is the first to explore the memory of the penal colony.

Abstract Name: Investigating the function of alternative 3' UTRs of the Drosophila translation elongation factor eEF1a1 in developing neurons using in-vivo reporters

After mRNA is transcribed from DNA, it must be modified in order to be translated into protein. One part of this processing is called polyadenylation, in which numerous adenosine nucleotides are added after the 3' end of the mRNA. For some genes, there are multiple possible cleavage sites, some closer (proximal) and others further (distal) from the end of the coding sequence. Distal cleavage results in a longer 3' untranslated region (UTR). These 3'UTRs directly determine RNA fate, as they contain binding sites involved in regulation of stability, localization, and translation. Selection of one cleavage site over the other is known as alternative polyadenylation (APA). Genes expressed in neurons tend to utilize the distal cleavage site more often. The consequences of APA are not fully understood, but its effect on RNA localization within the neuron (e.g Axon/Dendrite vs Soma) is thought to be important. By analyzing neuronal gene expression over development in the *Drosophila* visual system, we found a subset of genes which deviate from this trend. These genes utilize the distal cleavage site early in neuronal maturation, but undergo a switch to the proximal site later. We are focusing on the gene encoding eukaryotic translation factor eEF1a1, which participates in mRNA translation. Preliminary investigations found that the long UTR is only in the cell body and is prominent in the first 24 hours of neuronal development, while the short UTR localizes to the distal processes and is almost exclusively expressed later. We hypothesize that each UTRs has unique contributions to differential localization. Because eEF1a1 is essential for protein synthesis, we predict that changes in APA may reflect changes in where proteins are being made during development. We intend to investigate localization using GFP reporter plasmids for each UTR, and investigate regulation using microRNAs specific to one UTR.

Abstract Name: A Method for Portfolio Creation Utilizing Triangulated Maximally Filtered Graphs and Duality

This research project introduces a novel graph-theoretic method for creating stock portfolios utilizing Triangulated Maximally Filtered Graphs (TMFGs) and their dual graphs. TMFGs are created by using the highest values of a covariance matrix made from the daily percent changes of several stocks to identify pairs of stocks that rise in price together. In this framework, stocks are represented by nodes and trends shared by two stocks are indicated by edges. Utilizing the maximal planar property of TMFGs, dual graphs are made, in which every node represents a face from a TMFG and nodes are connected if they represent adjacent faces. Because every face in a TMFG is a triangle—which is also a clique of three stocks—each face is associated with a unique set of three stocks that have experienced similar trends. Thus, a unique portfolio of three stocks can be made for each node in a dual TMFG. After using Lagrange multipliers to create portfolios of minimal variance, statistical and machine learning methods are utilized to analyze centrality measures of dual TMFGs and the dynamic structure of TMFGs. Statistically significant patterns have been detected in the structure of both TMFGs and dual TMFGs that can be used to create subsets of the portfolios created by dual TMFGs that have an increased likelihood of outperforming the S&P 500.

Abstract Name: Can We Exploit Abnormal Stock Returns from Effective Date Delays?

This study examines the effect of governmental policy shock and stock market reactions due to delayed effective dates. The Efficient Market Hypothesis (EMH) has dominated modern financial literature since the 1970s. This paper seeks to determine whether abnormal returns can be exploited in the energy sector through governmental policy delays in announcement dates and effective dates. The daily stock prices of two energy sector market leaders were extracted from the beginning of the year when the announcement was made and through the second half of the year of when the policy took effect. Energy market leaders were determined by the criteria of market capitalization (Stock Price x Number of Shares Outstanding). By testing the Efficient Market Hypothesis (EMH) through an analysis of variance (ANOVA) and t-testing, the expected finding is that the semi-strong form of the theory holds, as the information delay is only short-term, but not long-term. Additionally, this study will also test the theory of Behavioral Finance, as this area of the Finance literature seeks to explain market behavior through investor sentiment. It is inferred that this is due to abnormal returns findings only occurring after the announcement date, but not after the effective date. The overall implication that this study seeks to accomplish is to determine whether certain sectors are efficient, the degree to which they are more efficient, or if the overall market is efficient. As a result, this study paves the way for further research through sector analysis in different industries to examine market efficiency.

Abstract Name: Beyond Dobbs: Public Opinion and State-Level Shifts in Abortion Law in Colorado, Nevada, and New York

This research evaluates shifts in the American public opinion and state policy on abortion rights by examining legislative changes and expert perspectives in Colorado, Nevada, and New York, comparing the period before the establishment of *Roe v. Wade* in 1973 with the period following its overturning in 2022 after the Supreme Court ruling on *Dobbs v. Jackson Women's Health Organization*. Existing research often emphasizes the federal and national implications of the overturning of *Roe v. Wade*, and few studies examine how individual states have distinct approaches to abortion and how these legal shifts intersect with changing public opinion, narratives, and lived experiences. Thus, this study examines the implementation of abortion legislation in Colorado, Nevada, and New York pre-*Roe v. Wade* and after its overturning, along with how these policies have been shaped and supported by public opinion by utilizing expert narratives and legal analysis, such as the story of abortion provider Ruth Barnett and the perspective of Dr. Mary Ziegler at UC Davis School of Law. This research concludes that there is a pattern of increasing abortion liberalization in parts of the United States, as proven by the legislative responses and changes within Colorado, Nevada, and New York, combined with the broader shifts in public opinion. This contrasts with the belief that the ruling of *Dobbs v. Jackson Women's Health Organization* greatly restricted abortion nationally. This study is limited to developments up to December 2023 and to the states of Colorado, Nevada, and New York. Therefore, future research should examine more recent legislative changes and other states' legislation to assess how abortion rights are evolving in the United States. Keywords: Abortion Rights, Pro-Life, Pro-Choice, *Roe v. Wade*, *Dobbs v. Jackson Women's Health Organization*, Colorado, Nevada, New York

Abstract Name: Fermentation Trends and Microbial behavior in Herbal Tea-Based Kombucha

Kombucha is a fermented tea beverage produced by a symbiotic culture of bacteria and yeast (SCOBY). Kombucha has been investigated for its functional properties and potential food safety applications. Natural additives, including honey and raspberry juice, may further modulate its microbial composition and antimicrobial activity; however, comparative evidence across tea substrates remains limited. This study aims to identify the fermentation dynamics, microbial profiles, and antimicrobial activities of green and chamomile kombucha and evaluate their antioxidant capacities and chemical compositions. Green and chamomile teas were fermented under controlled conditions for up to 14 days, with optional secondary fermentation using honey and/or raspberry juice. The fermentation progression was monitored through pH and °Brix measurements. The microbial population, including yeast, mold, and lactic acid bacteria (LAB), was quantified using 3M Rapid Yeast and Mold petrifilm plates and MRS agar. Antimicrobial activity of unfermented teas and kombucha samples was assessed against *Staphylococcus aureus* and *Escherichia coli* using a disc diffusion assay. Fermentation followed expected biochemical trends, with the pH decreasing from 7.28 on day 1 to 2.82 on day 14, and °Brix decreasing from ~9% to 5.8%, confirming active sugar metabolism and organic acid production. Yeast and mold growth peaked on day 7, decreased on day 10, and day 14. LAB colonies were observed on MRS agar plates by day 14, indicating the development of probiotic-associated microbiota. Preliminary antimicrobial data indicate a measurable zone of inhibition of 17 cm against *S. aureus* with green tea kombucha, while no inhibitory activity was detected against *E. coli*. These findings provide an insight into early fermentation behavior and microbial dynamics in green and chamomile kombucha systems. Ongoing analysis will determine how natural additives influence antioxidant properties, organic acid formation, and microbial interactions, supporting future development of functional kombucha beverages with enhanced health and food safety relevance.

Abstract Name: Sucrose vs. Nicotine Consumption in Male and Female Rodents

Nicotine usage persists among younger generations and continues to be a global health concern. Nicotine is a primary reinforcer that enhances the reinforcing effects of other rewarding stimuli, yet research on how sex differences influence nicotine and sucrose as a reinforcer in rats is limited. This experiment seeks to determine the way in which nicotine affects sucrose consumption and if it modulates sucrose drinking behavior in male and female subjects. In this experiment, both male and female rats were tested across a range of nicotine dosages. Current results show that across doses of nicotine there was a decreased consumption in both males and females. Females may show a greater decrease in consumption rates than males at a higher dose. This confirms that nicotine's impact on sucrose consumption appears to vary by sex, suggesting potential differences in how male and female rats respond to the combined reinforcing effects of nicotine and sucrose. This study continues to add information on how sex differences affect nicotine consumption with expectations of increased female sucrose-nicotine intake. It is also expected that females will show greater effects of nicotine with increased dosages across longer exposure.

Abstract Name: Effectiveness of Dried and Fresh Marigold (*Tagetes erecta*) in Adsorbing Methylene Blue from Aqueous Solutions

Dyes such as methylene blue pose significant risks to both human health and ecosystems, yet many existing removal methods are costly, generate secondary pollutants, and remain inaccessible in many regions. Marigold petals pose a promising alternative, as their porous, high-surface-area structure enables effective removal of methylene blue while remaining biodegradable, cost-effective, and readily accessible. This study investigates the effectiveness of *Tagetes erecta* (marigold) as a bio-adsorbent for the removal of methylene blue (MB) dye from aqueous solutions. The experiment specifically examines whether the physical state of marigold petals, fresh or dried, and the use of sulfuric acid activation impacts their effectiveness as a bio-adsorbent, an area not well-explored in existing research. Each preparation method followed a distinct sequence of activation and drying. Fresh petals were tested both with and without sulfuric acid activation, while dried petals were prepared using either sun-drying or oven-drying methods. These variations allowed for a direct comparison of preparation techniques and their influence on overall adsorption performance and efficiency. Overall, it was determined that dried marigold petals outperformed fresh marigold petals regarding MB removal from aqueous solutions. Kinetic studies were performed using first order and pseudo-second order models to understand the adsorption process. Comparisons of the adsorption performance of dried versus fresh marigold petals provide insights into the efficiency and process of bio-adsorbents. The findings suggest that marigold petals show potential as a cost-effective and environmentally sustainable bio-adsorbent for the removal of MB from aqueous solutions.

Abstract Name: Determination of K_m and V_{max} for Turnip Peroxidase and Catalase via Lineweaver-Burk Plots

This study investigates the enzyme kinetics of two distinct peroxidases: turnip peroxidase and catalase, utilising spectrophotometric assays at 470 nm and 240 nm, respectively. Substrate concentrations and reaction velocities were systematically varied to generate Lineweaver-Burk plots, enabling the determination of

kinetic parameters such as K_m and V_{max} for each enzyme. For turnip peroxidase, absorbance measurements at 470 nm were used to calculate product formation rates across a range of substrate concentrations. The resulting data yielded a V_{max} of approximately $-1.80 \mu\text{mol/min}$ and a K_m of 0.35 mM , indicating the enzyme's affinity and catalytic efficiency under the tested conditions. The negative V_{max} suggests possible experimental error or substrate inhibition, as noted in the dataset. Catalase kinetics were assessed using absorbance at 240 nm, with substrate concentrations spanning from 1 mM to 880 mM . The Lineweaver-Burk analysis produced a V_{max} of $1.97 \times 10^{-5} \mu\text{mol/min}$ and a K_m of -0.48 mM , again suggesting substrate inhibition or experimental anomalies. The instructions provided in the dataset emphasise the use of reciprocal plots and trendline analysis for accurate kinetic parameter estimation. Overall, the comparative analysis highlights the importance of precise experimental design and data interpretation in enzyme kinetics studies. Both datasets underscore potential challenges such as substrate inhibition and experimental error, which must be carefully considered when evaluating enzyme activity and efficiency.

Abstract Name: An Adult Attachment Style Approach to Understanding Musical Genre Preferences

Background: A newer area of adult attachment research addresses potential links between attachment styles and musical preferences; data suggest that people favor songs that reflect their attachment style. However, limited research has explored the connection between attachment security (vs. insecurity) and musical preferences. A key objective of this study was to investigate differences in attachment styles and their relationship to musical genre preferences. Method: The sample consisted of 505 undergraduate students at a mid-Atlantic liberal arts university ($n = 353$ females and $n = 152$ males; mean age = 19.13 years [$SD = 1.31$]). The survey was administered through an online research portal. Measures included: Demographic items and the Short Test of Music Preferences (STOMP; comprised of four musical factors: Reflective/Complex; Intense/Rebellious; Upbeat/Conventional; and Energetic/Rhythmic); and a four-category (Secure, Dismissing, Preoccupied, and Fearful) forced-choice measure of adult attachment styles. Results: A 2 (biological sex) $\times$ 2 (attachment security/insecurity) factorial ANOVA was performed for each of the four STOMP factors. For the Intense/Rebellious factor, there was a significant main effect for attachment style, $F(1, 501) = 8.90$, $p = .003$, with insecurely attached participants scoring significantly higher than securely attached participants. For the Upbeat/Conventional factor, there was a significant main effect for biological sex, $F(1, 501) = 9.18$, $p = .003$, with females scoring significantly higher than males. For the Energetic/Rhythmic factor, there was a significant main effect for biological sex, $F(1, 501) = 4.16$, $p = .042$, with males scoring significantly higher than females. Discussion: Obvious biological sex differences were to be expected with regard to musical genre preferences. However, the fact that attachment security (vs. insecurity) exerted an effect only for the Intense/Rebellious factor of the STOMP merits further consideration and exploration.

Abstract Name: An Attachment Styles Approach to Understanding the Burden of Somatic Symptom Disorder in a College-Age Sample

Background: Somatic symptom disorder (SSD), characterized by excessive thoughts, feelings, and behaviors surrounding physical sensations that cause distress or impairment, is increasingly understood to be influenced not only by physical factors but also by relational and psychological processes that shape how bodily sensations are experienced and interpreted. Research indicates that insecure adult attachment is linked to greater somatic symptom burden, including severity (e.g., reporting of higher somatic distress) and impaired emotional processing. The purpose of this ongoing study is to examine associations between adult attachment styles (secure vs. insecure) and somatic symptom severity among undergraduate students. Method: The current sample comprised 89 undergraduate psychology students with mean age = 19.57, SD = 2.13), who completed an online survey comprised of: Demographic items; the Somatic Symptom Scale-8 (SSS- 8; developed to assess severity of burden associated with SSD) and a four-category forced-choice measure of adult attachment styles (Secure, Preoccupied, Dismissing, & Fearful). Results: Preliminary analysis with a 2 (biological sex) x 2 (attachment Security vs. Insecurity) factorial ANOVA on SSS-8 total scores was significant, $F(1,88) = 4.80$, $p = .03$. Participants endorsing an Insecure attachment style had a significantly higher SSS- 8 total score ($M = 19.13$ [very high symptom burden], $SD = 5.88$) compared to participants who endorsed the Secure attachment style ($M = 15.72$ [high symptom burden], $SD = 5.86$). There were no other significant effects. Discussion: Preliminary results from this ongoing study trended in the expected direction, with an Insecure attachment style being associated with a greater somatic symptom burden. Interestingly, however, is that these preliminary data indicate a high symptom burden even for those participants who endorsed a Secure attachment style. Further data collection will be important to more fully assess this phenomenon and determine the existence of a possible cohort effect.

Abstract Name: Proteomic and Metabolomic Characterization of *Paruroctonus boreus* Venom

Very little is known about *Paruroctonus boreus*, (*P. boreus*), the Northern Scorpion. Venom proteomic and metabolic components will be identified and evaluated for potential anticancer properties. Interest is relevant in this potential anticancer property as other potential anticancer uses from scorpion venom arise. *P. boreus* specimens were collected at field sites outside of Warren, Montana. Venom was collected via manual milking, frozen, reconstituted into high purity samples and clarified before analysis via high-contrast UHPLC Q-TOF mass spectrometry. Identified molecules from raw venom will be searched against relevant databases for potential function. Bulk venom and specific proteins and/or small molecules of interest found in the venom will be used to assay biological effects on cancerous melanoma cells.

Abstract Name: How Witches Got Woke

This paper discusses how the word “witch” went from a term which denoted participation in criminal magical activity which was mostly forced onto people by their accusers to a label with which over one million Americans identify. It primarily focuses on analyzing how and why the modern witchcraft movement became disproportionately queer, female, and politically left-wing. In summary, those prosecuted for the crime of witchcraft did not all participate in any specific spiritual practice or share any specific demographic characteristic, but certain groups are overrepresented among them, namely gender nonconformity. The creator of the modern witchcraft movement posited that witches had been a secret group of pagans who secretly practiced pre-Christian rituals with fabricated evidence. While he took largely conservative positions on gender and sexuality, conflicts within the movement quickly led to rival factions which advocated for agitation against patriarchal gender norms and eventually eclipsed the influence of the conservative faction. The Internet era has seen the number of witches grow remarkably quickly, but also seen the movement more fragmented and less organized. While there is a fair amount of scholarship about specific events which contributed to the outsized presence of queer people, women, and leftists in the modern witchcraft movement, there is significantly less scholarship in which researchers make hypotheses for its cause. This paper argues that the causes for their outsized presence in the witchcraft movement is that their demographic characteristics are similar to those of people charged with the crime of witchcraft and an identification with a group which faced arbitrary violence for non-conformity. This paper is far from a definitive statement on this matter and instead intended to inspire future research.

Abstract Name: Hemin-Adsorbed Carbon Nanotube-PEDOT Coatings on Flexible Wires for Selective H₂S Detection

The detection of low concentrations of gaseous compounds, collectively known as gasotransmitters, such as NO, CO, and H₂S, is critical for understanding physiological mechanisms and pathways. Unfortunately, detection techniques encounter unique challenges when exposed to biological environments. Electrochemical methods offer multiple advantages for these investigations, including quick response, high sensitivity, and the potential for miniaturization. Carbon fiber microelectrodes are often used in these studies; however, they are limited due to both their high cost and fragility. The long-term goal of this project is to fabricate a flexible microelectrode with carbon-like surface properties and the dexterity of a metal wire, then modify this surface with an electrocatalyst to selectively detect the gasotransmitter of interest. Previous work focused on coating flexible PtIr wires with electrochemically reduced graphene oxide (ERGO) with and without polymerized 3,4-ethylenedioxythiophene (PEDOT). These efforts did not yield a carbon surface suitable for practical applications. This presentation will involve two phases towards the long-term goal of this project. The first phase involves polymerizing EDOT with polystyrene sulfonate (PSS) and acid-washed carbon nanotubes (CNTs) to function as a conductive layer on the electrode. These surfaces were probed using cyclic

voltammetry and scanning electron microscopy with energy dispersive X-ray (EDX) spectroscopy to ensure good coverage and electrochemical response. The second phase of this project applied these results towards fabricating a flexible microelectrode that can selectively sense H₂S against CO and NO. Here, hemin was initially adsorbed to the CNTs before entrapping them in PEDOT. Following polymerization, the electrode surface was treated with KCN in a pH 9.6 carbonate buffer to coordinate cyanide ligands to the Fe center of hemin. Amperometry was used to analyze and compare the microelectrode's response toward H₂S, CO, and NO.

Abstract Name: Visual Storytelling: Philadelphia's Resistance Against Gentrification

Philadelphia, PA is the city of black visual storytelling. Philadelphia preserves black spaces and its rich black history through movements such as the 'Mural Arts Philadelphia', the nation's largest public art program, and installation art dedicated to black people. Murals and installation art that captures blackness have become intertwined with Philadelphia's spatial design. Scattered across the city, there are creative public displays that empower black joy, black growth, black unity, and black history. When admiring 'Threads of Joy: Celebrating the Golden Years' by artist Kelley Prevard exhibited on 2000 S 58th St Philadelphia, 19143, she encourages viewers to gracefully embrace ageing while paying homage to Philadelphia's historical block parties and the residents of Ann Thomas, a senior housing facility. As gentrification stretches through neighborhoods, Black Philadelphia residents sustain its posture as a refuge for the Black community through visual storytelling. This presentation strives to magnify Philadelphia's black history and culture and cultivate appreciation for the efforts of its residents to preserve it through murals and installation art. By surveying murals and installations of art representative of black history and culture, there is evidence and inspiration on how to resist, preserve, and empower communities. I reason that visual storytelling is not simply ornamentation or an attempt to ignite change, but is an act of defense against gentrification. The murals and installations of black history and culture are barriers that Philadelphia residents use to protect themselves from the threat of unwanted reconstruction in their neighborhoods. This presentation will dissect the effects of visual storytelling in Philadelphia through the examination of murals and installations and bring understanding to how these artistic displays resist gentrification.

Abstract Name: A Comparative Study of Yoruba and Yakama Beadwork of the 20th Century: The Unseen Consequences of European Trade

This research investigates the 20th century similarities between the beadwork done by the African group based in Nigeria, the Yorùbá, and the Native American group based in Washington State, the Yakama. Of the many native cultural expressions beadworking itself is one of the most well known practices of colonized groups around the North American and African continents. Contemporarily, the Yakama use of glass beads is common though the practice has no basis in their ancestral roots. At the same time, the Yorùbá, known to

develop their own glass beads from around the 11th - 15th centuries, would suddenly lose the knowledge of their practices during colonial glass bead trade. Consequently, over time, components of the Yakama and Yorùbá beading arts have become more similar to each other while using the same materials and processes under colonial rule. Other historians have explored the topic of beadworking through the analysis of French documents and describe the trade agreements as a closed loop between “sellers”, French colonists, and the “buyers”, the Yakama and Yorùbá native peoples. This research will instead explore the reasons behind the Yorùbá and Yakama’s artistic similarities through analysis of their trade relationships to France and through a comparison of each group’s beadwork, formally, as well as historically. Research in this area brings to light the cultural loss of native groups during the bead trade and highlights the ways that native cultures in America and Africa have lost their original cultural practices due to trade agreements made during the 1500’s.

Abstract Name: Exploring The Links Between Water Quality and Social Equity In An Urban Stream Watershed

Reducing disparities in stream water quality is a key state-level priority in Georgia, USA. However, efforts to target communities for assistance are often hindered by the limited availability of empirical evidence identifying populations disproportionately impacted. This study seeks to address that gap by examining the relationship between stream water quality and social equity, with a focus on identifying the types of communities most burdened by water contaminants. We hypothesized that watersheds predominantly composed of low-income residents and minority groups (Hispanic and non-White populations) are more likely to experience degraded water quality. Our analysis focused on an urban stream network encompassing two creeks—Proctor Creek at Burbank Drive (AW-BB) and Proctor Creek at Grove Park (AW-GP)—as well as the Chattahoochee River (AW-CHR), which collectively represent communities with diverse socioeconomic characteristics. Water quality was assessed through physicochemical parameters measured with a Horiba U-50 portable meter, alongside microbial indicator testing conducted using IDEXX standard methods. In addition, windshield surveys provided observations of visible pollution differences, with affluent areas displaying cleaner environments compared to economically disadvantaged neighborhoods. Laboratory microbial analysis revealed significant variability in contamination levels, with higher microbial counts particularly evident at AW-GP, a predominantly low-income site. These findings highlight the complex interplay between socioeconomic disparities and contemporary water quality challenges. Results underscore the urgent need for targeted interventions that address environmental justice concerns and ensure equitable access to safe, clean water across Georgia. This research contributes to a broader understanding of how socio-environmental dynamics shape water quality disparities. By clarifying the connection between sociodemographic inequities and environmental conditions, the study emphasizes the importance of inclusive and equitable water management strategies that both advance environmental justice and safeguard public health.

Abstract Name: Identification and Exploration of a Parasitic Trematode (*Saccularina magnacetabula*) in Tampa Bay Ladyfish

Within Florida waters, the species richness of parasitic worms, specifically trematodes, has not been cataloged since the early 20th century. There have been few updates in recent years, leaving space for the question of existing host-parasite relations for the Gulf of Mexico and the Atlantic. In a 2022 study, a new genus and species of parasitic trematode in the family Didymozoidae was discovered in the fins of ladyfish, *Elops hawaiiensis*, and named *Saccularina magnacetabula*. A genetic and anatomical analysis was performed, laying the groundwork for new comparisons to this established species. In the fall of 2024, yellow parasitic worms were discovered within the fins of *Elops saurus*, a species of ladyfish in the Tampa Bay area. Since this initial discovery, we have performed thorough data collection, anatomy comparison, and genetic analysis of our unidentified worm and compared it to *S. magnacetabula*. This project explores the ecological, genetic, and anatomical aspects of this parasitic trematode. Here, we have performed DNA analysis on two specific genes and used an image analysis software for anatomical measurements. With this knowledge, we contribute to the newly developing list of parasite species inhabiting Florida and the geographical distribution of possible *S. magnacetabula*, which opens the floor for further study on host specificity for this trematode.

Abstract Name: Thematic Analysis of Queer Aesthetic and Identity in Rural Georgia

This study utilized Photovoice, a qualitative community-based participatory action research (CbPAR) technique, to explore how queer GCSU students define their own aesthetic and identity. Queer students may feel uncomfortable when directly asked about their identity; therefore, Photovoice can help participants share about their identity through a more conversational anchor point. Participants responded to the prompt “How do you present yourself to others?” by selecting photos that reflect their identity and aesthetic as queer individuals. Each participant then completed a semi-structured individual interview via Zoom and participated in an in-person focus group. During the focus groups, participants discussed how they hoped their data could be used to foster positive change at Georgia College & State University. I analyzed individual interview transcripts with Dedoose and used a phenomenological approach to uncover themes related to queer aesthetic and identity. After both transcript cleaning and coding, each participant read their transcript and codes to confirm that the results reflected their story. Emergent themes included: Stereotypes are unfortunately normal, People have multiple layers to their identity, Look good, feel good, play good, Strong and positive sense of self, and I’ve felt safe to express myself at GCSU. CbPAR and Photovoice help foster trust between researchers and historically exploited and excluded groups in science (HEEGS), as well as amplify marginalized voices in a research setting. They help to facilitate more ethical, empowering research with queer individuals. As a final showcase, I plan to create encouraging, bite-sized flyers, videos, digital galleries, and resource guides tailored to the needs of various campus groups, including athletic teams, academic departments, and diverse student and faculty demographics.

Abstract Name: Prevalence and effectiveness of visual abstracts in peer-reviewed scientific articles

Science communication has evolved drastically over the decades transitioning from solely peer-reviewed journals intending to communicate exclusively to peer scientists, to the usage of news outlets and social media venues to span diverse audience spanning both the scientific community and the general public. Paradoxically, the language complexity used in peer-reviewed journal articles has concomitantly increased. Filled with jargon and convoluted statements, science communicators and journalists—who frequently lack specific high-level training in the sciences—are left with minimal understanding of the articles they frequently report on. This communication gap opens new doors for misinterpretation of scientific findings, which in turn influences the way the public learn about and perceive science, oftentimes leading to misinformation and negative views towards science. In more recent years, some scientific articles have introduced visual abstracts to increase engagement and comprehension. Research shows that graphical and video abstracts have the ability to reach a wider audience when properly designed, regardless of their reading ability and knowledge of science. Despite their effectiveness, to date only a limited number of journals require or encourage the use of visual abstracts—and those that do range greatly in quality and effectiveness. My research seeks to examine the prevalence of visual abstracts in STEM and discuss existent research on their effectiveness, addressing their benefits and limitations. This work offers evidence-based suggestions on improvements regarding the implementation of more visual abstracts, and what this would mean for the future perception of science in the eyes of the public.

Abstract Name: Using Visual Data to Identify Deep-Sea Corals: Taxonomy, Abundance, and Distribution

Tropical and subtropical zones in the Atlantic Ocean harbor extensive mesophotic coral reef communities at depths from 30 meters to greater than 150 meters. Similar to shallow-water reefs, mesophotic reefs contain anthozoans of two classes: hexacorallia and octocorallia. Despite these reefs being more widely distributed than shallow-water Atlantic reefs, the identity, abundance, and distribution of community members remains cryptic when compared to shallow-water reefs. In part, this is due to the challenges that come with studying mesophotic communities - increased depth comes with increased difficulty in surveying and sampling. Furthermore, members of Octocorallia specifically are complicated to identify, with genetic sequencing or scanning electron microscopy (SEM) of sclerites (calcium carbonate pieces localized to soft tissue) being the main methods. Genetic barcoding of octocorals is tricky and limited, plus the number of taxonomists trained on sclerite identification is small. This project sought to: 1. Identify the abundance and distribution of both a mesophotic reef-building hexacoral genus, *Oculina* and additionally, an octocoral genus by the name of *Bebryce* in the Gulf of America. 2. Use SEM to confirm the identity of members of the mesophotic octocoral genus *Bebryce*, also sampled from the Gulf of America. For data regarding distribution and abundance, ROV footage was annotated using the platform TATOR, then verified and processed using Excel, RStudio and ArcGIS. *Bebryce* samples were prepared and then imaged using light microscopy and SEM. The results of this work showed distribution and abundance of both genera consistent with previous literature as well as support for the ability of *B. parastellata* and *B. cinerea* to hybridize.

Abstract Name: Characterization of the phage PaL41501, a potential therapeutic agent for treating multidrug-resistant *Pseudomonas aeruginosa* strains

Background: *Pseudomonas aeruginosa* is a primary pathogen that infects diverse tissues, including the ear, nose, urethra, soft tissues, lungs, and burn wounds. Some strains of *P. aeruginosa* are multidrug-resistant (MDR). We previously isolated and partially characterized a strain of Litonavirus named L41501 using the *P. aeruginosa* strain Boston 41501 as the host. Here, we present further virological findings for this bacteriophage strain regarding its potential as a phage therapy agent. Methods: Bacterial strains, including some MDR strains, were obtained from ATCC/BEI (Manassas, VA). The host range of the phage, its minimum inhibitory multiplicity of infection (MOI), phage-antibiotic synergy, and its ability to inhibit the host cell's biofilm formation were assessed using standard virological methods. Results: L41501 infected five MDR strains and two non-MDR strains, but was unable to infect eight other strains. L41501 remained biologically active after incubation of the phage for 75 minutes at pH 3-11 and temperatures from 37°C to 67°C, but was inactivated at 77°C. It causes lysogenic infections in the strain Boston 41501, and the resulting lysogens are resistant to reinfection by L41501. L41501 was unable to completely inhibit the growth of the host strain at an MOI of 1-1000. However, the phage reduced the minimum bactericidal concentration (MBC) of neomycin for the host strain by 4-fold at an MOI of 1. L41501 also decreased the host bacterial strain's biofilm formation by 6-fold at an MOI of 10. Conclusions: L41501 is stable across a broad pH and temperature range. It inhibits biofilm formation by *P. aeruginosa* strain Boston 41501. A pure preparation of L41501 cannot be used for phage therapy because of lysogenic infection, but it can be combined with antibiotics for similar applications. We are currently studying the mechanisms of lysogenic infection to develop a mutant L41501 that lacks the ability of lysogenic infection.

Abstract Name: Documenting a Regional Legacy: Tracing the Collaboration of Hank Marr and Rusty Bryant, 1954–1968

From the beginnings of jazz during the early twentieth century, the state of Ohio played an important role in the development and mobility of the genre. Predating the prevalence of air travel, Ohio served as a frequent stop for touring acts due to its location in the United States.. Although the idea of Ohio as a musical crossroads is what the state is most remembered for today in the context of jazz, it created and was home to

many local jazz musicians who never moved to a larger city, such as New York, Chicago, or Los Angeles. In an effort to preserve the local jazz history of the state of Ohio, this paper investigates the rich history of the relationship between two of the state's most revered local jazz musicians: Hank Marr (1927-2004) and Rusty Bryant (1927-1991). Although there is existing literature about these two musicians as separate performers, they had a lifelong musical relationship that has gone largely unnoticed since Bryant died in 1991 and Marr's death in 2004. By referring to existing literature in addition to thorough research of newspaper and music periodical archives, this study aims to provide a new, fuller, and comprehensive history of the complex and exciting relationship between Marr and Bryant. The overview begins with the release of "All Nite Long," the first major recording success on which the two collaborated, and ends with the musical separation of the two artists due to Bryant being signed to Prestige Records in 1968. Ultimately, through reconstructing the musical biographies of these two important musicians, the paper sheds light on a largely forgotten era in Ohio jazz history and aims to inform those who otherwise would remain in the dark about these two Ohio Jazz Musicians.

Abstract Name: Seeing into the Past: FSA Photographers Addressing the Medical Neglect of Rural Black Communities in the South

This project is an analysis of why and how the Farm Security Administration documented and portrayed Black people with visual impairments, particularly from rural areas of the southeastern United States, during the late 1930s and early 1940s. This project will emphasize the photographs and works of one of the FSA's key players, Marion Post Wolcott, in conversation with the general treatment of these individuals. The primary audience for my project is historians along with those interested in themes of race, class, and medicine. My research began with the Library of Congress, in which I noticed how often Wolcott took photos of African Americans with visual impairments (with most of them being blind or in clinics having their eyes checked). Since then, health records from 1944 have been located regarding eye health statistics across FSA borrower families, and they left a lot to be desired in discussion with possible racial bias and medical neglect of Black communities as few Black people were included in the physical examinations among said families. This discussion cannot take place without the consideration of location and redlining, thus making medical bias all the more possible. The goals of my project are to break down these photos so I can identify the purpose of why they were taken, what they say about rural Black communities across the southeastern United States, and explain exactly how these photos aided the greater Farm Security Administration in conversation with social and medical programs for those in need. As a result, the audience can thus understand the importance and meanings behind Wolcott's captured imagery.

Abstract Name: The Effect of Childhood Trauma on Associations Between Sleep and Emotions in Young Adults

Sleep plays a key role within socioemotional functioning, however the ways in which sleep interacts with experiences early on in life that can further moderate this relationship of emotional regulation are still misunderstood. This study aims to examine whether early exposure to childhood trauma moderates associations between sleep and everyday socioemotional outcomes in young adults. This work draws on data on a project led by Dr. Cara Palmer from the Sleep and Positive Socioemotional Dynamics Study (SAPS). This is a two week sleep assessment that is designed to better understand objective behaviors of sleep related to positive and negative socioemotional experiences in young adults. Participants ages 18-25 wore actigraphy sleep watches continuously for 14 days to assess sleep duration, sleep efficiency, and overall sleep quality. Each morning and evening participants completed surveys that further assessed their moods, social emotions, and depicted interactions they had each day before bed that are later assessed and coded on the Levels of Emotional Awareness Scale assessing levels of emotions. There were baseline assessments that included the Childhood Trauma Questionnaire (CTQ) and the Positive Childhood Experiences (PCE) measures to evaluate early adversity and protective relational factors . We expect that adequate sleep will be connected with more socioemotional functioning processes functioning, including greater positive affect and reduced emotional reactivity. Individuals with poorer sleep are anticipated to report greater emotional dysregulation and more negative emotional responses. Trauma exposure is hypothesized to strengthen these associations as participants with higher CTQ scores are expected to experience amplified negative effects of insufficient sleep. Findings from this study aim to clarify how sleep, trauma, and positive childhood experiences interact to shape emotional awareness. This work may inform prevention and intervention efforts by identifying trauma as a moderating factor that can impact socioemotional challenges among young adults.

Abstract Name: BORDER CORRIDOS: THEMES OF US-MEXICO RELATIONS AND HOW THE CORRIDO MAY HELP INFORM OUR PERSPECTIVE ON THE POLITICAL STATE OF THE BORDER AND IMMIGRATION POLICY TODAY.

The Mexican corrido has been a popular musical form of storytelling throughout the country's history. The corrido offers unique insight into historical events and figures that represent changing popular sentiment, cultural values and traditions. While corridos have certainly existed in Mexico prior to musical recordings, a corrido genre became very popular in the 1990's and early 2000's with acts such as Los Tigres Del Norte, Los Tucanes De Tijuana and Chalino Sanchez to name a few. Today, the corrido has evolved into many sub-genres, gaining huge audiences of younger fans, still maintaining the traditions connection to popular sentiment among the newer generations, as well. Broadly speaking, some topics discussed in the corrido include colonialism, regional and national politics, narco-culture and the US-Mexico border among many others. Interaction and relations between Americans and Mexicans have been widely expressed throughout the history of the corrido. This presentation will be an investigation into how the ever-changing relations between the United States and Mexico can be understood through the corrido, and how this history may help inform our perspective on relations between the two countries today.

Abstract Name: Storm Chasing Documentary: The Making of a Film on Severe Great Plains Storms

The Storm Chasing Documentary explores the University of Wisconsin–Whitewater’s field-based course GEOGRPY 492: Forecasting and Verification of Severe Weather, a program that provides hands-on training for future meteorologists and storm chasers. This project aims to document how the course enhances weather literacy, fosters collaboration between students and mentors, and deepens understanding of severe weather forecasting through experiential learning. The film captures students as they apply classroom knowledge to real-world storm environments, using forecasting tools, safety protocols, and data collection techniques. Through a combination of interviews, field footage, and reflective commentary, the documentary showcases how students analyze storm systems, navigate unpredictable weather conditions, and develop a scientific appreciation for atmospheric phenomena. The purpose of this project is not only to highlight the educational value of storm chasing but also to illustrate the ethical considerations and personal growth associated with participating in such high-risk, high-reward experiences. The documentary emphasizes mentorship, showing how experienced meteorologists guide students through both technical and emotional aspects of storm observation. By integrating storytelling and science communication, this project demonstrates how media can serve as a bridge between academic research and public understanding of weather. Ultimately, the Storm Chasing Documentary aims to inspire future students to engage with environmental sciences and to promote awareness of the power and beauty of severe weather while underscoring the importance of safety, ethics, and preparation in the field. I edited the Storm Chasing Documentary, organizing and refining field footage, interviews, and sound to craft a clear and engaging story. My goal was to balance the scientific aspects of storm chasing with the emotional and educational experiences of the students in the field.

Abstract Name: The Hinge of Collapse: Bodily Micromanagement in the “Unhinged Woman” Genre

This chapter argues that contemporary "unhinged woman" narratives reveal capitalism's gendered promises of success as structurally unattainable through what I term "bodily micromanagement" — the repetitive regulation that operates between conscious control and unconscious compulsion. These practices function as paradoxical bridges between the illusion of agency and its systematic negation, promising coherence while accelerating the very collapse they seek to prevent. The argument proceeds in three stages. First, I trace how concepts of gendered success shift across historical periods while remaining fundamentally unattainable for women. Second, through close readings of Sylvia Plath's *The Bell Jar*, Margaret Atwood's *The Edible Woman*, and Ottessa Moshfegh's *My Year of Rest and Relaxation*, I analyze how protagonists retreat to intensive bodily self-regulation when external promises of fulfillment fail. Esther's contraceptive obsession, Marian's systematic food refusal, and the unnamed narrator's pharmaceutical scheduling represent sophisticated attempts to control corporeal experience that ultimately intensify estrangement. Third, I develop a framework that reconceives these practices as active processes occupying the liminal space between social alignment and complete detachment. Rather than static symptoms, micromanagement unfolds temporally, allowing us to trace how tension between conscious intention and unconscious compulsion develops over time, revealing the gradual estrangement between mind and body that precipitates collapse. This analysis intervenes in both literary and feminist criticism by repositioning the "unhinged woman" genre as cultural diagnosis of how capitalism exploits and intensifies the fundamental tension between mind and body in women's experience. By theorizing micromanagement as process, the chapter reveals how capitalist ideologies intervene in the psychosomatic split, promising that rational self-control can master bodily experience while systematically generating the very mind/body estrangement that renders such control impossible. The conscious/unconscious split characterizing micromanagement becomes emblematic of how

gendered subjects navigate impossible positions through corporeal practices that contain the seeds of their own destruction.

Abstract Name: Analysis of early childhood sensorimotor control: A computer vision approach to motion analysis

Currently, there are limited standardized sensorimotor tests for young children under 5 years of age. This leaves out a significant period of growth where children with delayed motor development could be helped before entering schools. Atypical somatosensory processing may impact motor development, but children often do not receive a formal diagnosis until they are older where symptoms of dyspraxia or developmental coordination disorder (DCD) become more apparent in a structured environment. The Sensorimotor Performance and Rehabilitation Engineering Lab (SPRE), led by Dr. Chu, has developed the Somatosensory Test of Reaching (STOR). STOR is an assessment tool meant to evaluate a young child's somatosensory processing by using stickers in and out of a child's field of vision. A pilot study was conducted and determined that STOR would most likely present accurate results for children aged 10 months or older. Early detection plays a critical role in motor development, yet the current STOR assessments rely on labor-intensive manual analysis of video data. The purpose of this project is to determine the feasibility and accuracy of using computer vision algorithms to analyze children movement data. First, simplified videos will be used to test the computer algorithm. Then, through secondary data analysis, videos from actual data collections will be sampled to represent a range of participants. Feasibility of using computer vision algorithms will be determined by evaluating circumstances that the algorithm can function appropriately. Accuracy will be determined by comparing the computer vision analysis with original manual analysis. If this process can accurately code data, this would reduce the amount of time needed to code each video and streamline the process of simplifying analysis for STOR. This methodology can also be expanded to other motion analysis in children and potentially adapted into clinical use with mobile applications.

Abstract Name: Older Adults' Trust in Extreme Weather Information

With the increasing frequency of extreme weather events, older adults face higher risks in disaster situations due to health vulnerabilities and limited access to risk information. In this context, existing research has examined disaster risk communication, yet there remains a lack of research on how older adults evaluate the trustworthiness of different channels in a multi-channel media environment and on how trust functions within the information-seeking process. Drawing on the risk information seeking and processing (RISP) model, this study focuses on multiple stages that can lead to seeking and accepting relevant information and ultimately taking protective behavior. Key early stages in this process include risk perception and information

insufficiency. We aim to also place special focus on trust as a key psychological mechanism that can lead to positive outcomes for older adults. Specifically, this study investigates how older adults evaluate trust across four categories of channels: traditional media, professional meteorological platforms, social media, and interpersonal communication. Furthermore, it analyzes the role of channel-level trust in the relationships among information insufficiency, information-seeking, and decision-making, for several extreme weather scenarios: hurricanes, floods, tornados, and heatwaves. The research consists of a cross-sectional online survey to be conducted with older adults in Florida, and the data will be analyzed with multiple regression models. The findings are expected to provide more in-depth information about how older adults navigate the complex information environment about weather-related risks, and can guide improvements to emergency management, public policy, and media alerts.

Abstract Name: Wealth, Power, and Reform: A Global and Historical Approach to America's Pathways to Equity

Since 1989, the United States has remained trapped in a persistent cycle of wealth inequality that only continues to increase today. Whether driven by market failures or deliberate public policy decisions, this disparity is not accidental- it is systemic. This paper seeks to uncover the reasons behind the lack of meaningful progress over the past three decades and to explore potential pathways toward a more equitable society. It begins by acknowledging the importance of understanding how these disparities persist, particularly through the division of the population along both material and inherent lines as a necessary first step in recognizing the core issues at hand. Furthermore, by examining historical precedents and comparable global cases such as Vietnam, Iraq, and the recent Nepali Revolution, the analysis identifies strategies that may be adapted to contemporary conditions. The central argument emphasizes the necessity of gradual yet revolutionary policy reform grounded in socialist principles, aiming to curb excessive wealth accumulation and promote sustained redistribution. Furthermore, the paper highlights the importance of ensuring that economic justice extends beyond the middle class to include society's most vulnerable populations through continuous redistributions of wealth downwards through increased welfare programs. In an era defined by political polarization and rising living costs, this study contends that the United States must move away from systems rooted in exploitation and toward policies that foster collective well-being and economic fairness despite the continued propaganda against such.

Abstract Name: Structural Optimization of Saponin Adjuvant to Boost Immune Response

Many vaccines contain adjuvants, compounds that boost the immune response to a vaccine and allow for smaller dosages and fewer immunizations. Saponin-based adjuvants have gained more attention due to the

clinical success of the saponin QS-21, which is the current industry gold standard. However, though it is effective, QS-21 has inherent drawbacks that make it increasingly important to develop alternative adjuvants. One such alternative is VSA-2, a semisynthetic saponin adjuvant consisting of a synthetic side chain attached to the natural product Momordica saponin II (MS II). Its immunological effects are comparable to that of QS-21, with the added benefits of also being more sustainable to isolate and chemically stable. To investigate the effects of the side chain on the immunological function of MS II, structure-activity relationship (SAR) studies were conducted to evaluate the impact of the side chain's length and internal functionality. Taken together with previous SAR studies, the results indicate that both the terminal functional group and internal structure of the side chain greatly influence the adjuvant activity of semisynthetic saponins.

Abstract Name: Earthovia: Full Stack System For Interdisciplinary Education

This study examines how Interdisciplinary learning objectives, such as the United Nations Sustainable Development Goals (SDGs) and UNESCO AI competency framework can be effectively integrated into higher education curricula. These interdisciplinary objectives are often neglected as their integration requires educators to work with domains beyond their primary areas of specialization. Large language models (LLMs) have demonstrated immense potential to generate content across numerous domains. Nevertheless, existing literature shows that LLMs remain susceptible to hallucination and struggle with domain-specific questions requiring factual precision. To address this gap, we introduce Earthovia, a full-stack interactive web application, that employs a Hybrid Dense-and-Sparse Retrieval Augmented Generation (RAG) approach grounded in vector embeddings generated from United Nations Education for Sustainable Development (ESD) and UNESCO AI Competency educational frameworks. Earthovia supports educators in backward-design curriculum development starting from curating the course structure to module learning objectives to assessments, homeworks, and the last step being reading materials to ensure tight integration of interdisciplinary learning objectives at each step. Earthovia's interface provides clear Create, Read, Update, and Delete (CRUD) operations for every AI generated material to ensure final materials reflect educator's informed judgment. Earthovia is evaluated through a workshop with faculty participants using a within subjects, mixed methods approach where the participants engage in a manual and an Earthovia assisted integration round (IRB-26-0011). The changes are recorded as modifications in learning objectives, class structure, assessments, and curriculum materials on a worksheet. After each round, the participants complete a survey where we collect both quantitative data and qualitative reflections. The workshop concludes with a focus group semi-structured interview to collect user stories. All data collected is analyzed using the grounded theory approach to create en-vivo, procedural, and descriptive axial codings from which broader thematic categories are derived.

Abstract Name: Preconception and Prenatal Lifestyle Behaviors as Predictors of Labor and Delivery Outcomes

Preconception health reflects the physical and behavioral well-being of individuals of reproductive age, and unhealthy habits during this period may increase the risk of pregnancy complications. This study examined whether lifestyle behaviors before and during pregnancy were associated with adverse outcomes, including labor induction and cesarean delivery. A descriptive cross-sectional survey was conducted in April among 15 postnatal women aged 18–50 living in the Hampton Roads area. Participants were recruited using snowball sampling and completed an anonymous online questionnaire with approximately 76 items assessing sociodemographic characteristics, physical activity, nutrition, sleep, stress, physician guidance, and delivery outcomes. Women who were currently pregnant or had pre-existing chronic conditions were excluded. Results indicated that participants had a mean age of 26.67 ± 5.07 years. The average pre-pregnancy weight was 145.93 ± 19.93 lbs., which increased to 168.93 ± 15.82 lbs., representing an average weight gain of 23 lbs. Overall, 20% of women experienced medically induced labor due to preeclampsia, and 33.3% underwent emergency cesarean sections, most often because of difficult labor. Unhealthy lifestyle behaviors were also prevalent: 40% reported being “not very active,” 73.3% consumed processed or fast foods multiple times per week, and 60% slept fewer than six hours per night. Additionally, 93.3% stated they received no preconception physical activity counseling from healthcare providers. Findings suggest that lower physical activity levels, poorer diet, inadequate sleep, and elevated stress may contribute to increased pregnancy complications. While the results support the study’s hypothesis, the small sample size and demographic similarity of participants limit generalizability. Larger, more diverse studies are needed to further examine these associations and to support improved preconception counseling that encourages healthier behavioral practices.

Abstract Name: Effects on Mental Illness in Individuals with Familial History of Alcohol Use Disorder

This study aims to explore the differences in rates of depression, anxiety, stress, and alexithymia (a diminished capacity to both identify and describe emotions and appropriately manage problematic emotional states) in those with and without a family history of alcohol use disorder (AUD). Previous research has found that there's an increased risk of an individual developing AUD if it is present in their family history due to a combination of genetic and environmental factors. Approximately 50–70% of individuals with an AUD will be diagnosed with comorbid psychiatric disorder, including depression and anxiety. Although previous research has focused on how having a family history of AUD is associated with an individual's risk of other mental health issues the goal of this study is to bridge a gap in research by examining how those with and without a family history with AUD will score on multiple mental health related measures. This study also focuses on college aged students who are in environments more susceptible to experiencing these negative mental health challenges. Data was collected via SurveyMonkey from a college sample using the following questionnaires: Toronto Alexithymia Scale TAS-20: A 20-item self-report questionnaire that assesses questions related to alexithymia. Alcohol Use Disorder Identification Test: A 10-item screening questionnaire regarding alcohol use disorder. Depression Anxiety & Stress Scale: A 21-item scale self-rated questionnaire consisting of questions related to depression, anxiety, and stress. Demographic information such as age, sex, gender identity, a history of mental illness for both for the participant and their family

members. We expect individuals with a family history of AUD to score higher on all mental health and alcohol use measures than participants who do not have a family history of AUD.

Brogan Ward

Discipline: Dance

Authors:

Abstract Name: Fragments of One

This dance explores themes of overcoming internal barriers and the mental "fronts" people put up when in different situations. The choreography blends hip hop with contemporary movement in a way that captures constant shifts and waves of emotion representing the pullbacks of fear and false comfort, contrasted by the pushes of optimism and self-growth. The nine dancers represent the various internal "masks" that an individual might rely on as they navigate these competing forces. The aim of the work is to show that hope is rarely linear in its progression; instead, it appears in powerful surges that mirror the same speed at which insecurities can return. Through this interplay, the piece highlights how difficult finding clarity and strength within one's own mind may be to some. This choreographic research builds on the idea of using movement to make internal experiences visible to its audience, as well as exploring how to portray emotional tension by patterns of expansion and contraction. The work also experiments with how the body can reflect vulnerability, resistance, and growth through shifts in dynamics and intention in spacing. The central purpose of this project is to investigate storytelling through movement, translating emotion into a physical vocabulary. That purpose continued to guide my creative process in structure and phrasing. The expected outcome of this research is a deeper understanding of how physicality can make emotions legible, both for the performers and audience members. Through creating and rehearsing this work, the project has expanded my creative process by refining my use of dynamics, timing, and dancer interactions to explore more abstract concepts.

Abstract Name: Anti-Augustan or Pro-Augustan: The ending of the Aeneid-An inquiry into the language

"Imperium sine fine"- "empire without end"- are the words of Vergil, Rome's greatest poet. His monumental epic, The Aeneid, was written to evoke the mythic foundations of Rome and to trace a divine lineage from Aeneas to Augustus. The poem's climatic finale in book XII concludes with the death of Turnus. The Aeneid's final scene has been greatly debated amongst scholars. Two views have come from this debate: anti-Augustan and pro-Augustan. The focal point is the anger of Aeneas. Furthermore, the violence of Aeneas has been viewed as a critique on Augustus. This paper argues that the anger of Aeneas is justified. Moreover, that it is not a critique on Augustus but recognition on his rule. Vergil indicates that Turnus' was destined to die for his killing of Pallas and his taking a spoil of war, the belt of Pallas. By applying a philological analysis of key passages in the Aeneid combined with a look at the historical background in which the Aeneid was produced helps in understanding these passages. This also includes ancient commentators and evaluating the work in relation to the moral values of the ancient Romans. As stated by Karl Galinsky: "The Roman reader would not have been concerned about his capital punishment in the final scene of the epic."Throughout the Aeneid,

Vergil sharply contrasts Aeneas and Turnus. Vergil makes it clear that it was destined that Aeneas would establish Rome, and Turnus was destined to die.

Abstract Name: Conjugation of the Proteasome Inhibitor Bortezomib to the TROP2 Antibody to Directly Target TNBC Cells

Triple-negative breast cancer (TNBC) is an aggressive form of breast cancer with low survival rates after metastasis. Bortezomib (BTZ) and other proteasome inhibitors (PIs) have been shown to kill TNBC cells in vitro at similar rates to Multiple Myeloma (MM), a blood cancer for which PIs are FDA-approved treatments. However, TNBC is a solid tumor, making it difficult to target with PIs, as the body clears them out before they reach the tumor site. BTZ also has off-target effects, leading to cardiovascular, gastrointestinal, and neurotoxicity. Identifying a way to directly target the TNBC cells provides a solution to reduce the toxic effects of BTZ while also ensuring the cancer receives the drug prior to systemic clearance. One way to target TNBC is by synthesizing an antibody drug conjugate (ADC) attached to BTZ. TROP2 is overexpressed in TNBCs, making it an ideal target for ADC therapy using TROP2 antibodies. My goal in this project is to synthesize an antibody drug conjugate with BTZ linked to a TROP2 antibody, sacituzumab, leading to direct targeting of BTZ to TNBC cells. This requires a novel multiple-step synthesis to create a linker in which the drug is attached to the antibody, so that it can be cleaved within the cell to release the drug. During the synthesis phase, many steps will be taken to ensure the linker is following the desired formation, including using analytical devices like NMR. After the linker is successfully made, it will be added to the TROP2 antibody using previously optimized conjugation conditions. After successful conjugation, the ADC will be tested in vitro alongside free BTZ to see if the ADC gets cleaved and releases BTZ in biological conditions, and if it kills TNBC at similar rates to free BTZ, ensuring its structure and function were not affected.

Abstract Name: Carl Jung's Cognitive Function Theory: Beyond the MBTI

In this work, we apply computational methods and machine learning to evaluate Carl Jung's original personality theories using quantifiable data. We derive mathematical proxy equations for Jung's eight cognitive functions and calculate them using a publicly available dataset of approximately one million responses to the statistically supported Big Five Inventory (BFI). While contemporary personality psychology relies on trait-based models such as the Big Five, Jung's cognitive-function framework remains influential despite its limited empirical validation and its popular association with the Myers-Briggs Type Indicator (MBTI). This study returns to Jung's Psychological Types to isolate the conceptual definitions of each function and map them onto measurable Big Five traits through theoretically informed weighting schemes.

These proxy functions are then evaluated using a permutation-based null model to assess whether their interrelationships align with Jung's predicted function pairings. Finally, we apply Principal Component Analysis (PCA) to visualize the latent structure of the computed functions and examine whether they form distinct dimensions or collapse into broader trait components. This approach provides a large-scale empirical test of Jung's typological claims, assessing whether these constructs meaningfully align with measurable trait dimensions or whether their structure diverges from current scientific models.

Abstract Name: Nucleoid Compaction and Chromosome Segregation in a Filamentous Sporulating Soil Bacterium

The increased frequency of antibiotic-resistant organisms is a major medical, agricultural, and ecological concern. *Streptomyces* are Gram-positive, filamentous, sporulating soil bacteria that produce a majority of medically relevant antibiotics. *S. coelicolor* is the typical model species used to study the genus, and is an excellent model organism to study cell division due to its complex life cycle. To increase understanding of the *Streptomyces* life cycle, strains that express deletions of conserved cell division genes *ftsK* and *ftsQ* have been constructed. Previous lab members have identified additional genes that may act in a compensatory manner for each gene deletion. *ftsK* is a DNA translocase that encodes an ATPase, which uses energy from ATP hydrolysis to ensure each spore receives a complete chromosome. Despite this gene being conserved, its deletion in *Streptomyces* does not result in a significant aberrant phenotype. A conserved gene encoding a Type VII Secretion System (T7SS) encodes an ATPase that exhibits high sequence similarity to the ATPase encoded by *ftsK*. To determine whether this T7SS compensates for a deletion of *ftsK*, strains expressing deletions of *ftsK* and the T7SS-encoding gene have been constructed. If a significant aberrant chromosome segregation and compaction phenotype is observed, it indicates that this gene product likely impacts cell division. *ftsQ* encodes a protein that acts as a scaffold to recruit the master cell division protein, *ftsZ*, and other essential cell-division machinery. *ftsQ*-null mutants can accumulate mutations that restore sporulation. One set of these mutations is in the *lsr2* gene (*lsr2**), which encodes a transcriptional repressor of biosynthetic gene clusters. To determine how this set of mutations in *lsr2* suppresses the deletion of *ftsQ*, various genetic fusions to the reporter gene, EGFP, have been constructed to assay activity under mutant conditions, which will likely reveal a mechanism of suppression.

Abstract Name: The Hobo Code: A Language Unspoken

This research delves into the inner workings of Hobo culture and the vast visual language shared by immigrant workers, okies, bohemians and famous blues artists in America - the Hobo Code. With a broad system of pictograms, Hobos were able to covertly communicate with an entire subculture of workers across

the American West. Whether it was to signal that water and food was available in an area, or to alert Hobos of police enforcement, this shared language strengthened a marginalized community. By examining the extensive history of U.S migration and unravelling the social hierarchies in the 1900s West, this topic questions how Hobos are commonly generalized today, and analyzes what their true nature and intentions were. This research on the Hobo code uses the history of a form of visual communication to look inside the minds of both men and women who dedicated their lives to travelling on the rails, seeking work, and creating adventure along the ride.

Abstract Name: A Regional Differences Approach to Understanding Ageist Views and Behaviors among University Students

Introduction: Ageism remains prevalent in the U.S., manifesting in discriminatory behaviors typically displayed by younger populations. However, there may be regional variations in ageism, particularly in regions of the U.S. where there is a high percentage of older adults (65+). The purpose of the present study was to determine if regional differences in ageist views and behaviors exist among university-age students. Method: The sample consisted of 521 undergraduate students (mean age = 19.56 years) enrolled in psychology courses at liberal arts universities in Virginia (n = 288) and Florida (n = 233). In addition to the collection of demographic information, measures included the 29-item Fraboni Scale of Ageism (FSA), which measures cognitive and affective qualities of ageism, and the 20-item Relating to Old People Evaluation (ROPE), which measures positive and negative ageist behaviors exhibited by individuals throughout their everyday activities. Results: Independent samples t-tests were performed to compare data from students at the Virginia and Florida universities on the ageism and ageist behaviors measures. Results of the t-test for FSA scores were statistically significant [$t(519) = -2.30, p < .05$]. The subsample of Florida university students had significantly greater ageist views ($M = 57.41, SD = 9.95$) compared to the subsample of Virginia university students ($M = 55.51, SD = 8.88$). Results of the t-test for the ROPE were not statistically significant [$t(519) = .84, p > .05$]. Discussion: Where one lives may play a pivotal role in their experience of growing old in America. Age friendliness may vary by state, depending on age demographics and population aging rates. These findings aligned with a study of all 50 states, where ageism was found to be more prevalent in northeastern and southeastern states (including Florida). Further research in this area is required to elucidate the impacts of this societal phenomenon.

Abstract Name: From the Feed to the Bleachers: Student Perspectives on Social Media Production and Game Attendance

This study examines the extent to which institutional social media production influences student attendance at

college basketball games, an increasingly relevant but understudied aspect of sports communication. As athletic departments enhance their digital presence through cinematic edits, motion graphics, trailers, and promotional storytelling, questions remain about whether these production efforts actually motivate students to attend games in person. Existing research often focuses on digital engagement metrics such as likes, views, and comments, yet provides limited insight into how production quality shapes physical attendance decisions. To address this gap, the project centers on qualitative insight grounded in student experiences. By interviewing one student from an HBCU (North Carolina A&T State University) and one student from a PWI (University of North Carolina at Chapel Hill), this research explores how fans interpret, respond to, and engage with their school's official men's basketball Instagram content. These conversations, supported only by past attendance numbers for contextual background, highlight how production style, financial considerations, and perceptions of authenticity influence whether students choose to attend games. Prioritizing lived experience over numerical correlation, this approach highlights motivations, expectations, and barriers that traditional quantitative research methods can often overlook. Comparing responses across an HBCU and PWI setting further illustrates how differences in resources, media strategy, and school culture shape the effectiveness of digital promotion. Ultimately, this study aims to expand the broader conversation about sports marketing in higher education by providing insight into how students perceive institutional social media and how those perceptions relate to in-person attendance. By prioritizing lived experience, the project emphasizes the value of student voices in understanding contemporary fan behavior.

Abstract Name: Mechanical Properties of Tough & Stretchable Slide-Ring Hydrogels

Two polymer chains, joined by a fixed crosslink have limits to their stretchability, however, Slide-ring materials which resemble molecular necklaces have greater stretchable properties. Slide ring hydrogels are a hydrogel composed of a polymer string which is threaded through lamp shade shaped rings, capped on the ends with larger molecules keeping the rings trapped in the structure, and having its rings crosslinked with other rings on different strands. The Hydrogel formed now gets its stretchable properties not from chemical bonds but from the mechanical sliding of the rings on the polymer strands. The benefit of this slide ring hydrogel is that there is very little wear and tear after repeated usage compared to other gels and rubbers as there are no chemical bonds being stretched only mechanical sliding. The research of these hydrogels included overall synthesis, tensile testing, and figuring out applications. For the main chemistry portion of the presentation it will include things like Polyethylene glycol bis(amine)(PEGNH₂) synthesis from polyethylene glycol(PEG), getting the inclusion of the rings in the structure using hydroxypropylated α -cyclodextrin (HP α CD) as the rings, the end capping, and the cross linking using Divinyl Sulphone (DVS). For the other portions of the presentation, it will include applications of the hydrogel like flexible electronics, tissue engineering, membrane technology, and sustainable soft materials.

Abstract Name: Mitigating Climate Change Through the Application of Thermoelectric Effects in Waste Heat Recovery

My project addresses society's need of growing demand for renewable energy. My research developed a novel apparatus that will generate electricity from extreme temperature differences. The temperature difference will come from harvested waste heat in order to further cool down the atmosphere. Since there is a high societal demand for a diversification of energy that does not depend on fossil fuels, or have loud moving machinery that disrupts neighborhoods, I anticipate this generation technology will contribute to the future of renewable energy. The technical methodology of my generator only requires an electrical current and temperature difference between two surfaces. I will analyze how thermoelectric effects heat convert to electricity through using a thermoelectric effect apparatus as a thermoelectric effect generator (TEG). The TEG developed in this experiment performs the Seebeck effect in which the temperature difference between the hot junction and the cold junction produces a voltage that sends a current to flow in this open circuit. My hypothesis is that if the temperature gradient is higher, in the range of 100°C-120°C, the voltage output will increase, in the range of 1mV-5mV, therefore producing more electricity. The results of this research show that the relationship between voltage generated and temperature difference is a linear increasing relationship. I have also analyzed the direct relationship between platinum resistors and temperature and inverted relationship between thermistor output data and temperature. I plan to expand my research to increase the scale of the generator. I anticipate that the larger scale will produce more electricity. I also plan to modulate the parameters set for platinum resistance and thermistors in order to maximize the amount of electricity generated.

Abstract Name: Microfluidic Diode Valves for Point of Care Diagnostics

This study looks at how microfluidic diode valves can be used to create point of care testing devices with similar efficacy to PCR tests. The goal is to develop portable, timely, and accurate point of care testing devices capable of performing more complex detection methods. The microfluidic diode valves are constructed of an inlet and drain made of conjugate pad with a channel in between, which are then covered by mylar on the top and bottom. A solution is added to the inlet, which flows through the channel and to the drain. By manipulating the surface of the mylar in the channel with hydrophobic materials, the flow speed of the solution can be controlled. Ultimately a scalable time delay will be created that can manipulate the timing of reactions to improve the clarity of the results. Data was collected to see how well these time delays work. Preliminary results show that while it is possible to create them, keeping them consistent is challenging. Further analysis will be presented, including steps being taken to help improve the reliability of these time delays, as well as what it could mean for the future of point of care testing in a resource limited setting.

Abstract Name: Ultrasonic Information Broadcasting for Multi-Device Communication in High-Noise Environments

This project will introduce a new encoding format utilizing ultrasonic signals for wireless data transmission between several devices in noisy, chaotic environments. Unlike optical methods, like QR codes, that require line-of-sight or visual clarity, ultrasonic communication (ranging between 18-22 kHz) uses inaudible sound to carry encoded data to nearby receivers omnidirectionally. This will allow continuous communication between a large number of devices without needing paired connections or a WiFi network. The encoding scheme will be based on the frequency-shift keying (FSK) method and will use error-correcting algorithms to ensure data can still be obtained in the presence of noise, reverberations, and signal loss. The encoding will allow a variable data transmission rate from 100-1000 bps and a data range from 1-15 meters, depending on the various environmental conditions. Use cases for this transmission method can include, but are not limited to, contactless check-ins, proximity authentication, IoT device configuration, information for museums/exhibitions, and cellular-like emergency broadcast systems in areas without internet access. This research will assess the packet delivery rates and reliability in different noise conditions (as high as 85 dB) and in different architectural environments. Because the communication method relies on low-cost hardware (i.e., standard speakers/microphones) and has no internet capabilities, this method may prove advantageous for resource-limited situations. The approach will yield proof-of-concept results and performance evaluations suggesting its potential for real-world settings.

Abstract Name: The Colonial Mindset Behind Blood Quantum: A Tool of Indigenous Erasure

This research examines the colonial origins and ongoing impacts of blood quantum laws on Indigenous tribes in the United States. Introduced by colonial and federal authorities in the late nineteenth and early twentieth centuries, blood quantum policies served as tools of settler colonialism designed to diminish Indigenous populations over time. The purpose of this research is to demonstrate how these policies function as instruments of erasure and statistical genocide. This project examines how the colonial mindset behind blood quantum has been internalized and adopted by some Indigenous communities. As blood quantum requirements grow more restrictive with each generation, many tribes continue to experience population decline. Some have already moved away from using blood quantum for enrollment, while others are considering similar changes. To complete this project, I used a combination of qualitative methods, including analysis of historical government records, tribal enrollment policies, and key scholarly works such as *Beyond Blood Quantum* and *The Great Vanishing Act*. I conducted interviews with Norbert Hill, a contributor to both volumes, along with Megan Minoka Hill. Both are Indigenous scholars and leaders who discussed the implications of blood quantum and potential alternatives. The goal of this project was to better understand how blood quantum laws, originally imposed by colonial and federal authorities, continue to affect how Indigenous people define identity, claim tribal membership, and uphold sovereignty. This research also examines how current enrollment policies might be reformed through a decolonizing approach that moves away from colonial frameworks. By exploring alternatives such as lineage-based or reduced-fraction criteria, the project aims to halt the decline of sovereign Native nations and support their continued survival.

Authors:

Abstract Name: The Effect of Suburbanization on Biodiversity

Since the introduction of Levittown in the 1940s after World War II, suburban communities have been the fastest growing developments for families. (Nelson, Williams, L.J., 1999). The introduction of the first G.I. bills after the second world war subsidized the construction and purchase of single-family homes, and there have been additional government subsidies to encourage the sprawl of suburban life since the initial introduction to facilitate this rapid growth. There is a correlative relationship between the growing suburban and single-family living and the damage to local ecosystems and diminishing populations of native species due to the negative externalities of the added pollution and depletion of resources. The research intends to solidify the connection between horizontal building expansion to the declining population of pollinating species by examining the behavior and externalities of growing suburban communities and their ability to support natural ecosystems.

Abstract Name: The Evaluation of the role of the transcription factor PU.1 in breast cancer cancer-associated fibroblasts

Macrophages are normal immune cells. In tumors, they are convinced by tumor cells to promote tumor

progression. Here, tumor-associated macrophages (TAMs) provide tumor growth, survival, and metastasis signals. We found that the protein PU.1 is essential for normal macrophages to become TAMs. Here, PU.1 deletion in TAMs in mice reduces BrCa growth. Another key cell type in tumors are fibroblasts. Like TAMs, cancer-associated fibroblasts (CAFs) 1) are present in great number; 2) drive tumor progression; 3) suppress the immune system; and 4) promote treatment resistance. Therefore, like TAMs, CAF density is linked to a poor prognosis. Interestingly, PU.1 has been shown to have functional relevance in fibroblasts, with inhibiting PU.1 reducing their function in non-cancer models. From our background in studying PU.1 in BrCa and its discovered function in fibroblasts, our objective is to evaluate the role of PU.1 in BrCa CAF function. Our hypothesis is that like in non-cancer models, PU.1 will have functional relevance in CAFs. First, using cell proliferation assays and gene expression analysis, we found that inhibiting PU.1 reduces mammary fibroblast proliferation and fibroblast marker and function gene expression. We then exposed fibroblasts to triple negative breast cancer (TNBC) and luminal B BrCa cells. Interestingly, TNBC, but not luminal B BrCa, cells promoted increased PU.1 levels in fibroblasts. Last, we used genetically engineered mice to delete PU.1 specifically in fibroblasts. Like our cell assays, PU.1 deletion in fibroblasts reduced TNBC, but not luminal B BrCa, growth. Total findings indicate that PU.1 in CAFs promotes tumor progression in TNBC, but not luminal B BrCa. From this, therapeutic targeting of PU.1 in CAFs could be a viable strategy to treat TNBC, which has a high degree of treatment resistance and limited effective treatment options.

Abstract Name: Prominence of Antisocial Personality Disorder in Violent Crime

Violence has become a widespread and growing phenomenon, with rates of violent crime increasing despite professional efforts to reduce it. The cause of violent crime across the world is something that these professionals have wondered about for generations. While many researchers have investigated external influences, one influence that should be considered is mental health. Antisocial personality disorder (ASPD) has been shown to be associated with behaviors that result in criminality. To research this relationship, a collective meta-analysis was conducted. While much of the research done on this topic was qualitative, seven studies provided sufficient data for a quantitative analysis. From these sources, five commonalities were discovered: (1) aggression, (2) impulsivity, (3) psychopathy, (4) recidivism, and (5) substance use disorder. Preliminary analysis identifies a significant relationship between antisocial personality disorder and these five characteristics. These prominent characteristics have been established with violent behavior, resulting in violent crime. The prominence of this disorder within the criminal justice system could provide insight into how to reduce the rising number of violent crimes across various societies. With this information, professionals can take a step back and reassess their approach to reducing violent crime.

Abstract Name: IgM hantavirus (Sin Nombre virus) ELISA for free-living deer Mice from northwest Oklahoma

Hantaviruses are an emerging zoonotic disease and are the etiologic agents of severe acute respiratory diseases: hantavirus pulmonary syndrome (HPS) or hantavirus cardiopulmonary syndrome (HCPS). Human hantavirus infection occurs through inhalation of excreta from reservoir hosts, which include rodents, shrews, moles, and bats. We are conducting a hantavirus (Sin Nombre virus [SNV]) surveillance in a free-living deer mice population located in northwest Oklahoma. To do so, we optimized an ELISA method for the detection of SNV IgM and IgG antibodies. The development of an SNV IgM ELISA complements another project that characterizes horizontal SNV transmission of wild-caught deer mice in a semi-natural enclosure.

Abstract Name: Oral administration of fluoxetine with L-Dopa further disrupts behavioral self-control in male *Betta splendens*

Recent research examined whether *Betta splendens* can exhibit behavioral self-control in a discrete-choice instrumental task for food reward. Male, but not female, bettas spontaneously preferred a larger-later (LL) reward over a smaller-sooner (SS) reward across repeated trials, demonstrating self-control without specialized training such as fading-delays procedures. Follow-up work showed that oral administration of the dopamine precursor L-DOPA disrupted this self-control, shifting preference strongly toward the impulsive SS option. Because selective serotonin reuptake inhibitors (SSRIs) like fluoxetine reduce impulsivity and aggression across species, the present study tested whether fluoxetine could restore self-control impaired by L-DOPA. Male bettas were randomly assigned to either a fluoxetine-only group (F) or a fluoxetine-plus-L-DOPA group (FD). Starting one week before testing and continuing throughout the study, all subjects received a daily oral dose of fluoxetine (2 mg/kg) at 9 a.m. Before each behavioral trial, FD subjects received an additional L-DOPA dose (60 mg/kg). During testing, fish completed three daily trials in a submerged T-maze, choosing between an immediate SS reward (1 pellet) and a delayed LL reward (3 pellets after 15 seconds). More than half of all subjects were removed due to abnormal swimming or atypical task performance, with attrition nearly twice as high in the FD group as in the F group. Among the remaining subjects, outcomes in the F group were variable: twice as many stabilized on the impulsive SS option as on the LL option. In contrast, all surviving FD subjects responded exclusively for the SS reward. These results indicate that this fluoxetine dosage does not rescue L-DOPA-induced reductions in self-control. Moreover, fluoxetine alone may further impair self-control in this paradigm. Future work could test alternative fluoxetine dosages, other SSRIs (e.g., sertraline), or co-administering carbidopa to isolate peripheral effects of L-DOPA on behavioral regulation.

Abstract Name: Rescue of cell viability in an optimized in vitro model of radiation induced anemia

Erythropoiesis is the generation of red blood cells (RBCs) through progenitor expansion during development. When exposed to radiation during cancer treatment progenitor cells may undergo programmed cell death due to DNA damage from radiation. This often leads to secondary anemia. Anemia is a condition where the body is unable to circulate enough oxygen to the cells due to a loss of RBCs or decreased oxygen carrying capacity of RBCs. Erythropoietin (Epo) Receptor (EpoR) is a crucial regulator of RBC progenitors. Epo binding causes a cascade of events in the cell, driving expansion of RBCs. EpoR knockout in mice is embryonic lethal, showcasing the importance of EpoR in erythropoiesis (Lee et al., 2001). Bcl-xL is an antiapoptotic protein that leads to increased cell division and pro-survival signaling downstream of EpoR. In the absence of Bcl-xL, red blood cell progenitors are pushed towards apoptosis (Güler, 2025). In our lab, when exposed to UV radiation, K562 cells have significantly reduced cellular growth and cellular viability. However, overexpression of the anti-apoptotic protein, Bcl-xL, rescued cellular viability post UV radiation in K562 cells, suggesting that Bcl-xL overexpression may recover cellular growth quicker than cells without the overexpressed protein. Since K562 cells are not an accurate model for erythroid maturation and development, we further used KITCAT cells, a cell line that has the ability to mature similarly to RBCs. KITCAT cells when exposed to radiation also exhibit significantly reduced cellular growth and cellular viability. We will present data on the ability of Bcl-xL to rescue from radiation induced death in KITCAT cells. Morphology data will show what KITCAT cells look like pre and post radiation. Therefore, our data supports that we have an efficient model for radiation induced anemia and have demonstrated that Bcl-xL overexpression is a potential approach to protecting erythroid cells from radiation-induced apoptosis.

Abstract Name: Maternity and the aging brain : Understanding the link between reproductive trauma and dementia risk in women

The prevalence of dementia and its associated costs are on the rise, as the total number of people with dementia is projected to reach 82 million in 2030 and 152 million in 2050. As research continues to explore the biological and ecological factors that may aid in its manifestation, it is important to understand sex-based biopsychological experiences that may affect an individual's long-term brain health. This project aims to examine the biological factors surrounding pregnancy, specifically traumatic birthing experiences, and how they correlate with the increased risk for women that gave birth developing dementia in later life. This project focuses on three major forms of reproductive and birthing trauma that are statistically linked with the increased risk of cognitive decline in older women who gave birth during their reproductive period. Additionally, it synthesizes information from cohort research studies examining physical indicators of traumatic birthing experiences (e.g., pre-eclampsia, stillbirths, and recurrent miscarriages) and their association with dementia diagnosis. The conditions explored in this paper are commonly related to dementia through shared pathways such as vascular abnormalities (specifically in relation to hypertensive disorders and dysregulation) and impaired endothelial function. By identifying these overlapping pathways, this project aims to clarify which traumatic birthing physical indicators may serve as early indications of cognitive decline as well as understand how both biological and psychological mechanisms work simultaneously. Determining these risks will contribute to improved risk assessment for women and aid in building efficient dementia preventive methods, as well as to develop ways to enhance the birthing experience.

Abstract Name: Comparative Analysis of the Cultural Values of 20th Century Nigeria and the United States Through the Depiction of Christ in Art

In the early 1900s, both the United States and Nigeria experienced significant Christian movements that reshaped cultural values and practices in the respective societies. In the United States, the American Liturgical Movement, stemming from the Roman Catholic Church, promoted active participation in Christian practices, countering the observational participation of the time. In Nigeria, Episcopalian prophets such as William Wadé Harris revitalized Christianity in West Africa, opening doors of personal relation and reflection through Christianity following the Age of Prophets in sub-Saharan Africa. This study examines these Christian movements through artistic interpretation, focusing on the depiction of Christ in art, and interpretation of common stories focusing on Christ in order to compare values of Nigeria to the United States due to the similar timing of Christian movements in the 20th century. In order to compare and contrast the aesthetics of art, artworks such as "Head of Christ," created by Waller Sallman in 1940 in the United States will be compared to "Veronica Wipes the Face of Jesus," created by Bruce Onobrakpeya in 1969 in Nigeria. In the United States, interpretation includes relaying the cultural values of individual connection through the active personal reflection deriving from the American Liturgical Movement, comparing it to the aftermath of the Age of Prophets in Nigeria, promoting allegory of societal hardships and individual reflection through the historical context of each Christian transformation going on at the time. Using the aesthetics of art to relay interpretation and importance of each culture displayed through the figure of Christ, the cultural values of the United States and Nigeria will be compared through each respective scope of Christianity.

Abstract Name: Creating 3D Digital Twins of Civil Infrastructure Using Visual Sensors

The goal of this project is to use an array of visible light cameras to generate a 3D surface model (digital twin) of roadways while driving over them. Currently, there are other methods of generating these models, the closest one being LIDAR, which uses pulses of light to measure the distance from the sensor to an object. The methods the project uses are Structure from motion, which is well established as a computer vision system for robotics to detect objects in 3D space. This method uses multiple images of the same scene to triangulate the relative location of points in the image to the camera sensors. Doing reconstructions this way requires that the cameras be calibrated to find their intrinsics and extrinsics (internal properties like focal length, central point, and distortion, and their external position and orientation). This is done using OpenCV, a Python package designed for photogrammetry, which has functions to calculate the properties based on a known checkerboard pattern captured in several images varying in position and orientation. Then, using the intrinsics and extrinsics of the cameras, the structure-from-motion program OpenMVG can accurately triangulate the

feature points in any set of images with enough overlap (roughly 70%). This creates an unscaled collection of points related to their relative location (this is called a point cloud). A GPS module that runs simultaneously gives accurate extrinsic location information at 10Hz, which is then interpolated with an IMU (inertial measurement unit) using a method called dead reckoning. The combination of the GPS and IMU gives accurate location information at 400Hz, while the cameras run at 200Hz. This can result in a point cloud model that is then scaled to the real world with an accuracy of around 5-15mm.

Abstract Name: Visualizing Vertebrate Anatomy: The Educational Impact of Scientific Illustration

Clear diagrams are essential for understanding complex anatomical relationships in comparative vertebrate anatomy, an intensive course focused on the evolutionary relationships of vertebrate forms. In BIOL 402 at Virginia Commonwealth University, repeated student feedback has indicated that photo-based dissection manuals are more difficult to interpret than illustrated guides. To address this limitation and evaluate the educational impact of customized materials, a new set of anatomical illustrations was developed to support laboratory instruction. Laboratory practical exam scores from previous cohorts of BIOL 402 were analyzed to identify the lowest performing anatomical subjects for each specimen. Based on these findings, dissections of the dogfish shark and domestic cat were conducted to obtain accurate visual references. Live observational drawings and photographic documentation were used to construct the initial illustrations, which were refined through comparison with existing anatomical diagrams. All information labels and anatomical structures were reviewed and approved by the course instructor to ensure accuracy. These illustrations will be implemented in upcoming sections of Comparative Vertebrate Anatomy during the spring semester. Student feedback and future exam data will be collected to evaluate whether custom illustrations improve anatomical comprehension, laboratory performance, and overall educational outcomes.

Abstract Name: Stativity and Intransitive Forms in Chuj

The purpose of this study is to describe the forms and functions of stative predicates in Chuj, a Mayan language of Guatemala and Mexico. Statives in Chuj are typically marked with a specific stativizer morpheme, -an, which attaches to positional and verbal roots. Previous work (Henderson et al., 2018) proposes a two-way distinction between temporary, spatial Davidsonian states expressed by a stativized positional followed by a directional (POS-DIR), and characteristic, individual-level Kimian states expressed by reduplication of the stativized positional (POS-REDUP). This paper uses data comprising of over 600 sentences elicited from a native Chuj speaker also fluent in English. While the data does support treating -an as a general stativizer and confirms that directionals are independent verbs that can follow stative predicates, no productive reduplication of stative predicates was found, and directionals do not consistently mark stage-

versus individual-level readings. Instead, directionals appear to be only necessary on elements where orientation or path alter the meaning of the verb root, and the permanence of a state is encoded elsewhere as an additional predicate. The data also shows that the intransitive suffix -il can attach to transitive roots in contexts where -an might be expected, suggesting potential overlap of pathways for deriving intransitive and stative predicates in Chuj. These findings challenge a simple mapping between stative morphology and level of state, and contribute to broader theories of how languages encode temporary versus characteristic properties.

Abstract Name: Exploring Generation Z's Interaction With Voice Assistants in Online Shopping: A Multi-Method Approach

The present study explores how Generation Z interacts with voice assistants and reacts to their product recommendations when shopping online. This research combines the Zaltman Metaphor Elicitation Technique and an eye-tracked product choice experiment, guided by the Technology Acceptance Model, the Media Richness Theory, and the Visual Attention Theory. This design captures the cognitive, emotional, and attentional processes influencing the intention of using voice assistants and the likelihood of following their product recommendations. The Zaltman Metaphor Elicitation Technique reveals that while cognitive load for low-enjoyability products was reduced, skepticism persists in product categories where personal preferences and emotional connections are stronger. The product choice experiment further demonstrates that when voice assistants recommend products, those products attract greater visual attention (e.g., a higher number of fixations), especially for low-enjoyability items like detergent and drills. However, participants tend to rely on their own preferences for high-enjoyability products, such as bicycles and couches, despite engaging with the recommendations, as shown by the average fixation duration. These results suggest that voice assistants are most effective in assisting Generation Z's decision-making for products they have limited experience with or interest in. In contrast, recommendations have less impact when Generation Z has emotional or aesthetic preferences. The findings highlight that marketers should tailor voice assistants' recommendations by product category to increase Generation Z's engagement.

Abstract Name: Leveraging Machine Learning and Natural Language Processing to Analyze Sentiment Variation in Biblical Translations of John 6

This study investigates how modern natural language processing (NLP) techniques can illuminate differences in sentiment and meaning across Biblical translations, focusing specifically on John 6. While Biblical translation has long been influenced by linguistic, cultural, and theological decisions, recent computational methods provide new ways to quantify these translational choices. Building on emerging scholarship that applies sentiment analysis and semantic modeling to sacred texts, this project aims to determine whether

measurable patterns of emotional tone and lexical variation can be detected across translations representing distinct philosophies from word-for-word to paraphrastic renderings. To explore this question, five English translations of John 6 were collected and processed using a combination of lexicon-based sentiment scoring (AFINN), BERT-based contextual sentiment classification, word-frequency visualizations, and cosine similarity comparisons. These methods allow for both numerical and qualitative insight into how sentiment and semantics shift from one translation to another. The findings show that while the overall emotional structure of the chapter remains stable, subtle differences emerge in polarity scores, contextual sentiment categories, and lexical patterns, especially between translations with contrasting linguistic styles. Semantic similarity analysis further highlights clear clusters among translations with shared philosophies and greater divergence between literal and paraphrastic versions. Together, these results suggest that machine learning can meaningfully complement traditional textual scholarship by quantifying how translation decisions shape tone and interpretation. The discussion situates these findings within broader conversations about translation reliability, the limitations of NLP models, and the appropriate role of technology in studying sacred texts.

Abstract Name: Prevention of Cold-Induced Apoptosis using Mitochondrial and Plasma Contributions of Human and 13-Lined Ground Squirrel Platelets

Platelets are small cell fragments found in the bloodstream that play a critical role in blood clotting. Donated platelets, crucial in medical emergencies across the globe, can only be stored for 3-5 days at room temperature before they must be discarded due to microbial contamination and degradation. Additionally, when human platelets are stored at refrigeration temperatures for prolonged periods of time, they lose functionality and undergo apoptosis, or programmed cell death. The 13-lined ground squirrel (*Ictidomys tridecemlineatus*) has adapted such that their platelets are able to withstand prolonged exposure to “refrigeration” temperatures of 4°C, an adaptation utilized during long periods of winter torpor. As these organisms regain body temperature post-hibernation, their platelets remain intact and retain functionality, making them an ideal model organism for studying mechanisms applicable to the cold preservation of human platelets. To evaluate these possible mechanisms, human and squirrel platelets have been stored in both human and squirrel plasma at refrigeration temperatures to determine platelet viability. Platelet apoptosis has been measured through Annexin binding and flow cytometry. Cell viability has also been assessed using a TMRE assay to determine mitochondrial contributions to the cold-induced apoptotic tendencies of platelets. Results obtained from the use of these methods have allowed further isolation of apoptosis prevention mechanisms and specification of assays to narrow possible contributing factors. Identifying this protective factor to prevent apoptosis could dramatically extend the shelf life of human platelets, reduce waste, and increase the distance in which platelets can be transported for use in the medical field.

Abstract Name: Exploring the Relationship Between Resilience, Grit, and Stress Levels in Undergraduate Pre-Health Students

Burnout rates are high among healthcare professionals, driven by both professional and personal factors. Literature shows that burnout can be reduced by building coping mechanisms, such as grit and resilience, to help individuals manage stress. Cultivating these traits early in a health professional’s career, such as during undergraduate studies, may better prepare them for future challenges. However, baseline measurements of physiological and psychological stress, resilience, and grit in pre-health undergraduates are lacking. We hypothesize a strong positive correlation between physiological and psychological stress levels, and a strong negative correlation between both grit and resilience with these stress levels. To test this, we extracted cortisol from saliva and nail samples for physiological data and used the Perceived Stress Scale, Adult

Resilience Scale, and Short Grit Scale for psychological measures. Among 72 diverse participants, we found a moderate positive correlation between grit and resilience ($r = 0.430$, $p < 0.01$), a weak positive correlation between perceived stress and salivary cortisol ($r = 0.242$, $p < 0.098$), and a weak negative correlation between perceived stress and nail cortisol ($r = -0.183$). These results highlight the value of targeted interventions to boost grit and resilience among pre-health undergraduates, supporting their capacity to manage stress during professional school and in their healthcare careers.

Abstract Name: Bridging the Gap: Strengthening the Integration of Theoretical Knowledge and Practical Application Among Social Work Students in Practicum Education

Social work education encompasses the integration of theory and practice as a fundamental aspect of professional competence. However, many students face challenges in applying theoretical frameworks during real-world client interactions in practicum education. As social work education continues to evolve, it seeks to adopt best practices and better prepare students for their professional roles. Despite concerns about the gap between theory and practical application being raised over a century ago, this gap appears to be as pronounced as ever. This "theory-practice gap" can lead to uncertainty, decreased confidence, and limit skill development among students. Social work students must successfully link theory to practice to be adequately prepared for the profession. Practicum education is fundamental to the pedagogy of social work and requires students to achieve mastery. This study aims to explore strategies for strengthening the connection between classroom learning and field-based practice, thereby enhancing students' ability to critically apply theory in real-life social work situations. Given the significance of field-based learning in social work education, it is essential to empirically examine students' experiences to inform the ongoing evolution of this vital educational practice. Social work is one of the fastest-growing professions of the 20th century, and the demand for skilled professionals continues to rise due to the increasing mental health crises in our socio-political climate. This study aims to use its findings to help institutions effectively train social work students at both undergraduate and graduate levels. Moreover, this study aims to enhance the knowledge and skills that students acquire at practicum agencies, better preparing them for the professional world.

Abstract Name: Investigation of Potential Effects of D-cycloserine on Behaviors of Anxiety and Parvalbumin Expression in Taconic's 22q11.2DS (Df(h22q11)/+) Mouse Model

Human 22q11.2 deletion syndrome (22q11.2DS) is characterized by a 3.0 Mb deletion on the 22nd chromosome. Prior research has confirmed its pathogenic role in neurodevelopmental disorders, including autism spectrum disorder (ASD) and schizophrenia. Dysfunction in prefrontal GABAergic interneurons, essential for information processing and social-cognitive functioning, has been observed in both preclinical models and clinical populations. A subset of these GABAergic interneurons express parvalbumin (PV+) protein and are surrounded by perineuronal nets (PNNs), which may help regulate firing, influence plasticity, and support executive functioning. Additional research indicates that 22q11.2DS mice display behavioral differences when administered an NMDA receptor antagonist, suggesting NMDA receptor hypofunction that may influence PV + GABAergic interneuron function. Moreover, elevated anxiety has also been observed in children with 22q11.2DS. Therefore, the present study assessed anxiogenic and stereotypic behavior in male and female 4-6-week-old Df(h22q11)/+ (n = 55) and their wildtype controls (n = 55) following a 7-day sub-chronic administration of NMDA receptor partial agonist, D-cycloserine (30mg/kg, i.p.) or saline using the light/dark box. Preliminary results show significant genotypic differences in total distance traveled, immobility, and ambulation, but no differences in stereotypic behavior or after treatment. Additionally, quantification of PV+ and PNN expression, as well as colocalization, is being performed using WFA staining within several areas of the prefrontal cortex. All stained slides were imaged using a confocal microscope at 60x magnification and were counted using NIH ImageJ software. Preliminary analysis shows a reduction of the number of PV + interneurons ($p < 0.05$) that may be restored in some PFC areas with D-cycloserine treatment ($p = 0.05$). By integrating these behavioral findings with alterations in PV+ and PNN expression, these data provide valuable insight into the underlying neurobiological mechanisms and potential therapeutic effects of NMDA receptor activation in 22q11.2DS.

Abstract Name: Which Wisconsin universities do Wisconsin CPA Firms prefer to hire from and why?

Do accounting firms value students for entry-level accounting positions the same way despite coming from different universities, specifically in Wisconsin? The purpose of this study is to examine the hiring preferences of Wisconsin CPA firms in terms of which Wisconsin-based universities they prefer to hire from. We will use data from a survey that my faculty mentor and I created and run an analysis based on the responses to the survey questions. The questions that we are asking range from the professionals' ranking the universities based on their preferences for those schools to how they picked their top choice from the collective rankings. My mentor and I believe that the research will suggest that Big 4 CPA firms will prefer students from larger schools near urban centers such as Marquette and UW-Madison while smaller CPA firms, such as KMA or Hawkins Ash will prefer students from regional state universities such as UW-Parkside or UW-Whitewater. Prior research has not examined the hiring market for accounting graduates in Wisconsin, and the information this project will provide will be beneficial to accounting employers, professors and students.

Abstract Name: A Mother's Love? A Biological Sex Comparison of Machiavellianism and Parental Bonding Types

Background: Machiavellianism, or the tendency to employ calculated and opportunistic behaviors for personal gain, is linked to early environmental/interpersonal factors, particularly parental bonding styles. Sex differences have been noted in both of these factors. This study aims to investigate how parental bonding styles affect Machiavellianism, utilizing the combined-scale parental bonding instrument, with a comparison of these effects across sexes. Method: Undergraduate psychology students (N = 239) completed measures: Machiavellianism Personality Scale (MPS), consisting of one total score (MPS) and five subscales; Parental Bonding Inventory (PBI), consisting of two scales, Mother and Father, each containing two dimensions. The PBI dictates five types of parental bonding—Affectionless Control, Affectionate Constraint, Optimal Bonding, Absent/Weak Binding, and Average. Results: Factorial ANOVAs, 5 (PBI; mother or father figure) x 2 (biological sex), were conducted to determine effects of parental bonding and biological sex on overall MPS scores. There was a significant interaction between biological sex and parental bonding type on overall mother figure (MF) MPS score. Mean MF MPS score was significantly greater for male participants than for female participants with the Affectionate Constraint PBI type and the Average PBI type; there was no significant difference for the Optimal Bonding, Affectionless Control, or Absent/Weak Bonding PBI types. Post-hocs indicated that the Absent/Weak Bonding PBI type scored significantly higher on the overall MF MPS scale than the Optimal Bonding PBI type. A significant main effect for biological sex was found on overall father figure (FF) MPS scale, indicating that male participants scored significantly higher than female participants. Conclusion: Machiavellian sex differences were replicated, as insecure (Absent/Weak) bonding resulted in higher Machiavellianism scores than 'secure' (Optimal Bonding). Further research into the Affectionless Control PBI type's individual effects on Machiavellianism is merited, due to the close relation between control and Machiavellianism.

Abstract Name: Insecure and Entitled: The Relationship between Academic Entitlement and Attachment Styles

Background: Academic entitlement is the tendency for students to possess externalized expectations of academic success while negating the role of personal responsibility. Attachment styles are individual patterns of relating to others, which have been correlated to a wide range of issues of social functioning and stress-reduction behaviors. However, little work has been done extending adult attachment styles to the field of educational research. The present study will serve as an analysis of the connection between academic entitlement and adult attachment styles. Method: Analysis consisted of 113 undergraduate students who completed measures including the: Academic Entitlement Scale (AES), consisting of two subscales, Externalized Responsibility and Entitled Expectations; Rosenberg Self-Esteem Scale (RSES); and Adult Attachment Scale (AAS) which was clustered into three categories—Anxious, Avoidant, and Secure. Results: The Externalized Responsibility subscale revealed a significant difference between AAS levels. Secure participants scored significantly lower on the subscale than Avoidant participants. The RSES revealed a significant difference between AAS levels. Secure participants scored significantly lower on the scale than Avoidant or Anxious participants. Conclusion: Preliminary results align with those expected from research into broader narcissistic entitlement. Reflecting the view of covert narcissism as an especially relevant

predictor of Anxious attachment, the Externalized Responsibility subscale of the AES, previously associated with personal control, may be especially salient for further research. Moreover, it is suggested that covert narcissism may explain the relation between academic entitlement and insecure attachment. The similarity between the RSES and the AES on AAS suggests an underlying factor—more research is needed.

Abstract Name: Identification of Leafhoppers In Vineyards and On Landscape Trees in Utah

Leafhoppers are small herbivorous insect pests which feed on the sap of many vascular plants. Several species of leafhopper are known to vector phytoplasmas, which are obligate intracellular bacterial parasites associated with a variety of plant diseases. Grapevines and landscape trees, both of which are important to Utah's economy and urban canopies, are susceptible to phytoplasma-caused diseases. This susceptibility warrants the identification of leafhopper vectors in vineyards and parks, which would provide insight into the development of preventative measures for growers to utilize across the state. In this study, leafhoppers were collected from vineyards and landscape trees throughout Utah and identified with DNA sequencing. Although leafhopper species may be distinguished through morphological traits, the additional use of molecular techniques allows species with similar morphologies to be differentiated. Collected leafhopper were photographed and then processed for molecular identification. The sequences were compared to other leafhopper sequences in the NCBI BLAST search for identification. Of the leafhopper species so far identified, *Fieberiella florii* was the only species found that has a known potential for vectoring phytoplasmas. *Candidatus Phytoplasma pruni*, which causes cherry buckskin disease, and *Candidatus Phytoplasma mali*, which causes apple proliferation are both known to be vectored by *Fieberiella florii*. Understanding that this leafhopper is present in Utah will allow growers to take the appropriate preventative measures against the spread of these phytoplasma-caused diseases.

Abstract Name: Mastering Enterprise Networks: A Practical Guide to Building Computer Network Systems

Mastering Enterprise Networks focuses on the development of an open educational resource (OER) textbook that is freely accessible to support student learning in computer networks. Enterprise networks are intricate large-scale systems that enable organizations to securely connect users, devices, and applications across multiple locations. They are a foundational component of modern communication, business operations, and cybersecurity. The goal of this research is to reduce financial barriers for students while working on instructional effectiveness and breaking down complex topics into teachable material. The textbook was created using open-source tools and aligns with coursework at different universities as well as high schools to

ensure accessibility and relevance. The content of the textbook was developed through the collaboration of students writing chapters on networking topics they wanted to delve deeper into and other students assuming the role of testers to ensure that the chapters written are clear and precise. According to our preliminary research, open-source materials promote access to education without compromising academic integrity. This project demonstrates the potential of OER to enhance learning experiences, encourage academic collaboration, and contribute to long-term affordability of higher education resources as the textbook has reached a wide audience from the United States, Canada, and Nicaragua as well as being peer-reviewed by the National Centers of Academic Excellence in Cybersecurity (NCAE-C) which is managed by the U.S. government's National Security Agency.

Abstract Name: Drunk Driving: A Crisis in Need of Reform

Drunk and impaired driving is all too familiar for far too many people in society. Regardless of how one has come into contact with the system, drunk driving is a major public health issue. With thousands of lives being lost every year, it is evident that the current system for handling these offenses is not an adequate deterrent for the behavior. Consequentially, improvements need to be made to this system to not only stop the behavior, but to save lives. Drunk driving has been a longstanding issue in society, and reforming the system has importance on a number of identifiable levels and areas. As research has indicated, drunk driving needs to be addressed through a combination of legal, educational, and social reforms. By taking a multi-faceted approach to punishing drunk driving offenders, the system can work better to prevent drunk driving before it happens and when it does, prevent offenders from re-offending. This research shows the structure of the current system, the flaws, and suggests a number of reforms to increase the effectiveness of the legal system. This research demonstrates the importance of a combination approach to the sanctioning of drunk driving offenses in order to successfully address the drunk driving public health crisis and save the lives of thousands each year.

Abstract Name: Revival Song: The Significance of Hymns in the First Great Awakening

This paper highlights the transition in church music during the First Great Awakening in Colonial America. It argues that hymns and new psalmody had a mutually beneficial relationship in the Awakening, as they aided one another in emphasizing personal salvation experiences. Prior to the Awakening, English-speaking churches in Colonial America sung almost exclusively literal translations of Psalms in a more formalized call-and-response format. While current scholarship on the First Great Awakening broadly analyzes the primary tensions and debates within New England churches regarding changes in music, it does not provide a comprehensive overview of the introduction of hymns in Colonial America. Despite this important shift in church music, most studies of the Great Awakening only scratch the surface of music's importance to the revival ethos. This paper analyzes primary source documentation concerning the response to and significance

of hymns and new psalmody in Colonial America. The writings of Great Awakening figures including Jonathan Edwards, George Whitefield, and Isaac Watts provide key insights into this transition and are supplemented by personal journals and newspapers from the period. Hymns were a major factor in the spread of the Great Awakening and gave individuals the means to express how the preaching impacted their lives. Instead of singing literally translated Old Testament Psalms, churches and individuals began to sing songs that reflected of their personal faith. Further, many of the hymns from this period became central to several church denominations in early America. Ultimately, this study underscores the central yet understudied role of music in the Great Awakening.

Abstract Name: Improving Tour Qualities of some TSP Heuristics using Tree-Penalized Distance Matrices

The Traveling Salesman Problem (TSP) is a classic NP-hard combinatorial optimization problem that seeks the shortest route visiting each of (n) cities exactly once and returning to the origin. TSP has numerous real-world applications, including vehicle routing, logistics, DNA sequencing, circuit board manufacturing, and urban planning. While exact solvers such as Concorde can guarantee optimal solutions, they become computationally infeasible for moderately sized instances (e.g.,) due to factorial growth in complexity. Consequently, heuristic algorithms—such as Nearest Neighbor—remain widely used for large problems because they are fast, though they often produce suboptimal tours. In this work, we propose a general framework for improving the performance of classical TSP heuristics by modifying the distance matrix. Specifically, we introduce tree-penalized distance matrices which combine the original intercity distances and tree penalties derived from hierarchical clustering trees. We use tree-penalized matrices to replace the original distance matrix to guide heuristic decisions. Extensive experiments on 40 benchmark datasets compare the performance of four well-known heuristics—Nearest Neighbor, Nearest Insertion, Cheapest Insertion, and Farthest Insertion—with and without the proposed modifications. Results show that the approach can significantly improve the quality of the tours generated by the heuristics, while maintaining practical runtime efficiency.

Abstract Name: Light Reflection Simulations for MAGIS-100

MAGIS-100 is a large scale atom interferometer based at Fermilab in Batavia, Illinois. Light pulses are fired within the 100-meter channel on atoms under the effect of gravity, with the intent on finding gravitational waves, and the ever elusive dark matter. Ensuring that the light pulses are properly timed and calibrated is an intricate process and requires considerable steps to mitigate any issues. Simulating the impact of diffracted beams is essential to reduce noise in the system and choose effective mitigation efforts. Using Mathematica, we worked to build reflected and diffracted beams within the tube, and also simulate which angled beams would be absorbed by different methods. These methods include baffles placed inside the tube, aquadag coatings, and oxidization coating solutions. These simulations are being used to find the most effective treatment and lower cost. Analysis of method effectiveness is also discussed.

Abstract Name: An Analysis of Literacy and its Impact on Crime

This study aims to find and analyze answers to the common stereotypes and assumptions that in the United States of America, the lesser educated are more likely to commit pettier and less severe crimes, such as drug dealing, loitering, or drug possession within a controlled amount. More specifically, this project seeks to answer the questions, "Do those with lower reading scores commit lesser crimes? Do those with higher reading scores commit the more sinister, severe crimes, such as murder, or grand larceny? And how does reading, and by proxy, education, actually affect crime, and can we take steps to address it effectively?" Through robust and thorough data analysis that implements regression techniques such as Least Absolute Shrinkage and Selection Operator (LASSO regression) and stepwise regression analysis, this study seeks to provide a detailed quantitative understanding of how literacy may prove impactful on the severity of crime committed, specifically in the region of Macon, Georgia. This study will also aim to tackle the common stereotypes surrounding poor education in the United States of America, as well as the history and reasoning as to why these stereotypes can form, thus prompting many solutions to fix them, guided by the initial results of the study.

Abstract Name: Rising Fuel Prices and Transit Demand: A Longitudinal Study of Five U.S. Metropolitan Areas

Previous research has suggested that rising gas prices are associated with increased public transit ridership, yet there remains a lack of recent empirical evidence exploring this relationship. In recent years, both ridership levels and fuel prices in the United States have continued to climb, emphasizing the need for updated empirical analysis. Moreover, researchers found a statistically significant correlation between fuel prices and transit use, even in highly automobile-oriented cities. This study aims to investigate the relationship between the average cost of gasoline per gallon and weekly ridership across five major US cities using a longitudinal study. The five cities include Atlanta, Georgia; Dallas, Texas; Los Angeles, California; Washington, D.C.; and San Francisco, California. These cities were selected for their diverse transit infrastructures and system designs. Data will be collected from multiple sources, including the Bureau of Transportation Statistics and the American Public Transportation Association. It is anticipated that the findings will support the existing literature by demonstrating that higher fuel prices correspond with increased public transit ridership. These findings might educate transit agencies and public policy decisions in assessing the reactionary nature of riders and fuel prices.

Abstract Name: Mahdism and Sudanese: History and Memory of an Islamic Movement in North America's Diasporic Sudanese Communities)

In 1881, Muhammad Ahmad, a sheikh in the Sammaniyya Sufi order, proclaimed himself to be the expected Mahdi and led a revolt that culminated in the creation of an independent state, the Mahdiyyah. At the time, British officials viewed Mahdist expectations in Sudan as a product of events and beliefs in Egypt, an idea which rested upon the Nile River uniquely connecting the communities of Sudan and Egypt. Later scholars have parted from this narrative and instead choose to focus on how Egyptian policies and attempts to end the slave trade contributed to the Mahdi's rise. Using a twofold ethnographic and historiographic approach which includes literature review, archival research, and observational fieldwork with the Sudanese community in Greensboro, North Carolina, this project seeks to demonstrate that neither of these arguments align with narratives in the Sudanese diaspora. These narratives, collected through in-depth semi-structured ethnographic interviews, place greater emphasis on Sudan's connection to West Africa than to Egypt. Moreover, they reveal a division between Eastern and Western Sudan, as well as the close association between Western Sudan and two of Sudan's most prominent political and religious organizations. The analysis of the Sudanese diaspora's memory alongside primary documentation reveals connections between Sudan and West Africa in addition to the relevance of Muhammad Ahmad's legacy to the conflict in Sudan.

Abstract Name: Applying Faith-Based Solutions to the Complex Foster Care System in Tennessee

The state of the foster care system in Tennessee remains an urgent issue as youth entering the system face a lack of support, as retention rates of foster families decrease, transitional programs fail to support the youth, and a lack of community involvement and awareness isolates the foster care population. This study examines faith-based solutions by applying a systems lens to a complex foster care system in Tennessee. 50% of foster families in Tennessee discontinue fostering after the first year, although when properly supported, the retention rate climbs to 90%. This study focuses on faith-based solutions to the complex foster care system of Tennessee, beginning by looking at the longitudinal study performed by the Belmont Innovation Labs relating to transitional youth in foster care and the statewide Every Child Tennessee initiative that addresses the four focus areas of foster care: Preservation, Recruitment, Retention, and Transition. To understand the interworkings of faith-based partnerships and community involvement in the foster care system of Tennessee and the lack thereof, we utilized a mixed-methods approach, performing quantitative surveys, partnering with non-profit Crowded Table to pursue practical solutions addressing the retention rate in Tennessee. Considering this data, we found that retention of foster families in Tennessee remains low due to a lack of faith-based involvement of partners and organizations, limited WRAP-Around Care, and limited mentorship opportunities. Our findings indicate that providing WRAP-Around care, mentoring resources, and data-based partnerships through faith-related organizations will create a more holistic, stable, and relational environment for complex family dynamics relating to the foster care community. Ultimately, our study suggests that practical support provided by faith-based organizations will advocate for foster youth and will transform the foster-family retention rate in Tennessee.

Abstract Name: Stateless Knowledge: Education as a Claim to Belonging

This project examines how stateless communities establish and maintain education systems in the absence of recognized nation-states. Focusing on three comparative cases, the Rohingya camps in Cox's Bazar (Bangladesh), Palestinian refugees in Lebanon, and Sahrawi camps in Algeria, it examines how schools emerge as political and cultural institutions that preserve identity, transmit civic memory, and assert belonging when citizenship rights are denied. Drawing from policy analyses, UNHCR and UNRWA reports, and NGO education frameworks, the study maps how communities adapt to restrictions on mobility, funding, and accreditation. It identifies the governance mechanisms, such as community education committees, diaspora teacher networks, and informal credentialing, that allow learning to continue even without legal recognition. These forms of "stateless schooling" challenge conventional assumptions about education as a state function, reframing it instead as a collective human right sustained through self-organization and transnational solidarity. The project employs a comparative governance framework to analyze three key dimensions: access (including gender and age inclusion), continuity (pathways to certification or external exams), and civic participation (student leadership and community decision-making). By highlighting the adaptive capacity of stateless educators and learners, this research argues that education can serve as a form of soft nation-building, preserving identity, fostering resilience, and maintaining the moral legitimacy of communities excluded from the international state system. Findings contribute to the growing literature on education in emergencies, stateless governance, and refugee self-determination, offering policy recommendations for humanitarian actors to strengthen education systems that exist beyond the nation-state.

Abstract Name: MyoWrist: Novel Designs for a Low-Cost, Intuitive Prosthetic Wrist

The wrist is a crucial part of a functioning upper limb, whether biological or prosthetic. However, wrists are quite complex, with three degrees of freedom and the ability to vary stiffness depending on the desired task. Because of this complexity, it has historically been difficult to develop functional, intuitive prosthetic wrists. Current designs lack the flexibility and dexterity present in biological wrists and can be difficult to control, resulting in muscle overcompensation and user strain or injury. Additionally, the average range in cost of a prosthetic arm is \$20,000-\$80,000, which presents a barrier to lower-income individuals. To address these shortcomings, we are currently prototyping and testing two lightweight, low-cost wrist designs that provide both flexibility and stability to the user. Our team, part of a larger myoelectric upper-limb prosthetic team, comprises four undergraduate engineering students. Our first wrist prosthetic includes a ball-and-socket joint

designed to enable all three degrees of freedom in the wrist and forearm: flexion/extension, radial/ulnar deviation, and pronation/supination. This joint also contains a spring mechanism to ensure the wrist restores back to its original neutral position. This design will interface with the larger team's prosthetic hand through carefully placed polyethylene fibers that replicate the tendon mechanisms in the body. The second design consists of two high-torque servos, one for pronation/supination and the other for flexion/extension, within a 3D-printed housing. It also features variable stiffness, allowing the user to more naturally grip and lift heavy objects. Both designs were modeled using SolidWorks and 3D printed, significantly reducing the cost of the wrist while maintaining structural stability. Next steps include design refinement, functionality testing, and client interaction. Ultimately, our prosthetic wrists will integrate with existing upper-limb prosthetics and offer a wide range of motion to users at a reduced cost.

Abstract Name: The role of the NDUF2.1 C366 residue in neuronal biology, neuronal behavior and its implications for neurodegeneration

Neurons rely on mitochondria for energy production and signaling. During energy production mitochondria also produce reactive oxygen species (ROS). While critical for signaling, ROS can cause mitochondrial dysfunction leading to neuronal dysfunction and neurodegeneration. Our lab previously identified the redox active NDUF2.1 C366 residue as critical for hypoxia/reoxygenation response in *Caenorhabditis elegans*. To investigate the role of NDUF2.1 C366 oxidation in neuronal function, we generated a cysteine to aspartate mutant, that mimics a locked oxidized state and C366S, a cysteine to serine mutant, that mimics a locked reduced state. We completed neurobehavioral assays using the model organism *C. elegans*, evaluating the function of dopaminergic, serotonergic, glutamatergic, GABAergic, and cholinergic neurons. We found that both C366D and C366S mutants' dopaminergic neurons functioned abnormally. It was also revealed that C366D mutant's GABAergic and cholinergic neurons functioned abnormally. Then, we completed genetic crossing of C366D and C366S mutants to investigate the mitochondria morphology, neuronal morphology of these mutations with microscopy. In the future, we aim to understand the role of NDUF2.1 C366 in mitochondrial function and neuronal death in neurodegenerative diseases.

Abstract Name: The Effects of Microgravity and Hypergravity Conditions on Neurotransmitters in the Brain

Space exploration has greatly expanded human knowledge, yet the physiological and neurochemical consequences of spaceflight remain incompletely understood. Reduced-gravity environments are difficult to reproduce on Earth, and available technologies offer limited capability for real-time, in vivo measurement of

neurotransmitters, hindering efforts to determine how spaceflight stressors alter brain function. Serotonin (5-hydroxytryptamine, 5-HT) and dopamine (3-hydroxytyramine, DA) are key neuromodulators that regulate mood, cognition, memory, and physiological homeostasis. Dysregulation of 5-HT and DA is associated with depression, anxiety, and impaired cognitive performance, increasing risks to astronaut well-being, crew cohesion, and mission success during prolonged isolation and stress. To address this gap, we developed a novel electrochemical sensing platform for real-time detection of 5-HT and DA in the mouse brain during simulated microgravity and hypergravity. These conditions were modeled using custom small-scale suspension chambers and centrifuges, respectively. Flexible glassy carbon microelectrode arrays (GC-MEAs) coated with a poly(3,4-ethylenedioxythiophene) (PEDOT)/COOH-functionalized CNT composite (PEDOT/CNT), coupled with optimized square-wave voltammetry (SWV), achieved enhanced electrochemical performance. SWV enabled well-resolved, linear detection of DA and 5-HT from 10 nM to 1 μ M, suitable for monitoring basal physiological levels. In vivo recordings demonstrated reliable detection of 5-HT in the hippocampus (CA2) and DA in the striatum, validated through pharmacological manipulation. PEDOT/CNT-coated GC-MEAs maintained stable electrochemical and sensing performance for up to four weeks for DA and one week for 5-HT. We are applying this technology to mice undergoing partial weight suspension (PWS) to model microgravity and complementary centrifuge-induced hypergravity paradigms, with electrodes implanted in the hippocampus and other relevant brain regions. This approach enables dynamic monitoring of neurochemical adaptations to altered-gravity environments, providing new insight into central nervous system responses to spaceflight-relevant stressors. Ultimately, these findings aim to support the development of countermeasures to protect astronaut mental health and maintain performance during long-duration missions.

Abstract Name: Assessment of Lamotrigine in an Organophosphate-based Rat Model of Gulf War Illness

Approximately 1/3 of veterans of the First Gulf War suffer from a chronic health condition known as Gulf War Illness (GWI). GWI affects multiple body systems, including the nervous system. Neurological symptoms include mood disorder and memory dysfunction. GWI is thought to be caused in part by deployment-related exposure to organophosphate (OP) chemicals, which include pesticides and nerve agents. These OP exposures have been determined to result in neurodegeneration, neuroinflammation, and epigenetic modifications, possibly underlying the development of GWI. Despite years of research, effective treatments for GWI veterans are lacking. Lamotrigine (LTG) is an FDA approved antiepileptic drug that has also been reported to be epigenetically active. LTG blocks histone deacetylase (HDAC) enzyme which is reportedly elevated in experimental models of GWI. We hypothesized that LTG, by virtue of its HDAC inhibition, could effectively treat neurological symptoms of GWI. Diisopropyl fluorophosphate (DFP) is an OP compound which mimics the effects of the nerve gas sarin under laboratory conditions. In this study, adult male Sprague-Dawley rats were exposed to DFP (0.5 mg/kg, s.c., 1x daily, 5 days) to mimic deployment-related nerve gas exposures. Three months post-exposure, rats were assessed for signs of mood and memory function. DFP-exposed rats exhibited significantly lower sucrose preference on Sucrose Preference Test indicative of anhedonia, spent more time in the closed arms of the Elevated Plus Maze indicative of anxiety, and demonstrated lower discrimination towards the novel object on the Object Recognition Test indicative of memory impairment. A subset of DFP-exposed rats were treated with LTG (30 mg/kg, i.p., 1x daily, 7 days). Statistically significant improvements in mood and memory function were observed in LTG-treated rats. Additional studies researching the molecular mechanisms of LTG are underway. These results indicate that LTG may be effective in treating symptoms of GWI.

Abstract Name: Ovarian Hormones and Electronic Cigarette Use in Young Women

Electronic cigarette (“e-cigarette” or “vaping”) use is increasingly common among adolescent and young adult women, yet no studies have tested whether ovarian hormone fluctuations contribute to vaping behavior. Prior cigarette-smoking research suggests that estradiol may enhance, and progesterone may dampen, nicotine reward, craving, and withdrawal, but hormone-informed e-cigarette studies are virtually nonexistent. This study evaluates whether vaping behavior varies with ovarian hormone levels and whether associations differ between naturally cycling (NC) women and oral contraceptive (OC) users. Participants were 60 young women (ages 16–22; 30 NC, 30 OC). At baseline, approximately 45% reported lifetime e-cigarette use, and about 25% reported current use. Among current users, daily vaping frequency ranged from 1–6 uses/day, and about 10–12% reported awakening at night to vape. Craving was present in ~20% of participants, with past-week urge severity ranging from 3–9, and ~10% reporting strong urges (≥ 8). Irritability or nervousness when unable to vape was endorsed by 6 participants, consistent with early dependence-like patterns. Over the past 30 days, vaping ranged from no use among non-users to near-daily or daily use among regular users, indicating substantial variability in exposure. E-cigarette use was reassessed at follow-up visits, providing repeated measurements across the menstrual cycle and the inactive/active pill conditions. Hormone assays (estradiol, progesterone, FSH, LH) are currently in progress. We will test whether (1) higher estradiol, lower progesterone, or a higher estradiol-to-progesterone ratio predict vaping likelihood or intensity; (2) within-person hormone changes better capture vaping fluctuations than absolute hormone levels; and (3) hormone-vaping associations are attenuated in OC users. Mixed-effects models will evaluate hormonal predictors with Group (NC vs OC) included as a moderator. This study provides one of the first hormonally informed investigations of e-cigarette use in young women and will determine whether momentary endocrine states influence nicotine-related behavior.

Abstract Name: The Benefits of Cartoons in an Educational Setting: An Examination of Cartoons' Impact on

Students' Participation, Attention, and Comprehension

This research investigates the relationship between student comprehension and the implementation of cartoons in cross-curricular K-16 educational settings. Our research is inspired by the art education graphic novel *What's So Great About Art Anyway* by Rachel Branham (2016), which illustrates her individual experience with her art education journey. This led us to create cartoons in our own unique styles surrounding the question, "Why do we want to become an art educator?" This was a prompt for our research notebooks in our introductory art education class. Because of the positive feedback we received from our professor and peers about our cartoons, we gathered supporting materials from our institution's library and online sources regarding the use of cartoons as a method for supporting students' education inside and outside of an art curriculum. In this research, we are expanding this question to include, "How do cartoons affect students' attention, comprehension, and participation in the K-16 classroom setting?" Further supporting our hypothesis will be investigations into contemporary cartoon implementation in the classroom through curriculum as well as our own autobiographical art examinations. Other studies surrounding the impact of cartoons in the classroom are often focused on a single subject area while neglecting to reference art as a tool for thorough understanding. By reviewing documents showing the implementation of cartoons in the classroom, we expect the outcome of our research to display student engagement, understanding, and visual literacy across multiple subject areas and ages. Our research and resulting curriculum will encourage dialogue about the cross-curricular applications of cartoons into core classes to improve students attention, comprehension, and participation.

Abstract Name: Comparative Study of Fiber Cells and Their Physiological Functions in Animals and Plants

This study explores the connection between structural support tissues in plants and animals by comparing skeletal muscle morphology in rodents to xylem tissue development in soybean stems. We aimed to understand how investment in physical support structures relates to function, such as strength and reproduction. This helps address broader questions about how organisms allocate resources to structure versus performance. For our animal model, using published literature, we collected cross-sectional data on muscle fibers. Specifically, we looked at fiber number, type, and cross-sectional area of leg muscles in mice and rats subjected to energy-consuming exercises (treadmill, ladder climbing). We then related these morphological measurements to functional strength and growth outcomes in response to different training. Results indicated consistent muscle hypertrophy across all studies with slight variation depending on type of training and fiber type tested. At the same time, we analyzed stem images from soybean plants grown in two field locations in Virginia, measuring xylem vessel size and number to assess investment in transport and support tissue as related to fruit yield potential. Trends suggest that plants with larger xylem investment show increased seed abortion due to carbon cost of building support tissue. Our comparisons of soybeans and rodent structural tissues showed that these trade-offs are visible and measurable across both systems, providing a foundation for future studies to explore how structural investment affects performance and reproduction across species.

Abstract Name: The Sensory Classroom: Understanding the Impact of Environment on Literacy for Students with Sensory Processing Disorders

This project investigates how sensory-friendly classroom environments influence literacy development among students with Sensory Processing Disorders (SPD). The central research question guiding this study asks: How does the physical and sensory design of the classroom impact literacy engagement and achievement for students with SPD? The purpose of this research is to synthesize findings across educational and psychological studies to identify evidence-based environmental strategies that foster inclusion, self-regulation, and academic success in literacy-rich classrooms. Existing scholarship demonstrates that traditional classroom settings – characterized by harsh lighting, inconsistent noise levels, and rigid seating – often hinder attention, motivation, and comprehension for students with sensory challenges. Conversely, classrooms intentionally designed to regulate sensory input – through flexible seating, structured routines, visual organization, and adaptive tools – create environments more conducive to literacy development and emotional well-being. This project employs a qualitative synthesis of current research, analyzing trends across empirical studies to evaluate how specific sensory modifications (lighting, noise control, flexible seating, and multisensory instructional tools) contribute to improved focus, reading comprehension, and writing fluency. The analysis also explores intersections between environmental design and multisensory literacy instruction, emphasizing the role of sensory regulation in academic engagement. Preliminary findings suggest that sensory-friendly environments not only enhance literacy outcomes but also promote confidence and positive associations with reading and writing for students with SPD. These conclusions will be discussed through visual models illustrating optimal classroom arrangements and sensory supports. Ultimately, this research contributes to a growing understanding of inclusive literacy pedagogy, demonstrating that intentional classroom design is integral to equitable literacy instruction for all learners.

Abstract Name: Analyzing Environmental and Geological Factors that Influence Bird Species Abundance and Distribution at Mundy's Landing

In Kentucky, there has been a dramatic increase in flooding over the past few years, destroying many lives, towns, and ecosystems. When considering the displacement and disruption of lives and ecosystems due to flooding, one species impacted that are often forgotten are birds. Birds play a variety of roles in ecosystems including pollinators, seed dispersers, and scavengers. The objective of this study is to determine the environmental factors, specifically geological, that drive richness, abundance, and distribution of bird species at Mundy's Landing, and determine the potential effects of flooding on those bird species and their habitat. Located on private property and bordering Woodford and Mercer Counties in Kentucky, Mundy's Landing area includes a variety of habitat types crucial for many bird species survival such as the Kentucky River, forested areas, and open pastures. A series of point count surveys consisting of visual and vocal cues of bird species were performed throughout the property's different habitats to determine which bird species were present in a habitat. Once bird species were identified, their conservation status was then analyzed through the IUCN (International Union for Conservation of Nature) Red List of Threatened Species to determine the species global extinction risk status. The categories of the IUCN's Red list utilized in this study include Critically Endangered, Endangered, Vulnerable, or Least Concern. Upon determining conservation status of species, their associated habitats were analyzed and allowed us to determine the habitats that were most

crucial for the species of conservation concern. These habitats include open forests, densely forested areas, and streamside forests, which host the most at risk species. This study highlights the importance of conserving habitats that are critical for the survival of bird species of conservation concern, many of which are threatened due to the increased frequency of flooding in Kentucky.

Abstract Name: HMGA1 Represses Oxidative Phosphorylation to Maintain Hematopoietic Stem Cell Quiescence and Long-term Regenerative Capacity

Introduction: Hematopoietic stem cells (HSCs) have the remarkable capacity to generate blood for the entire lifespan of an organism. While precisely regulated metabolism is required for HSC quiescence and regenerative function throughout life, factors governing these processes remain unclear. The gene encoding the High Mobility Group A1 (HMGA1) chromatin binding protein is highly expressed in HSC. HMGA1 modulates chromatin structure to activate transcriptional networks that promote proliferation and plasticity. Prior studies of single-cell transcriptomes in murine gut stem cells reveal that HMGA1 regulates genes involved in metabolism (Luo et al, JCI 2025). We therefore hypothesized HMGA1 regulates metabolic gene networks required for HSC function. Methods: To test this, we analyzed single-cell transcriptomes via RNA sequencing (scRNAseq) of HSCs from mice with intact or genetic deletion of HMGA1. Chromatin immunoprecipitation sequencing (ChIPseq) then identified HMGA1 binding sites in human HSC and progenitors (HSPC). We then performed Seahorse extracellular flux assays in murine HSPCs to measure oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) as indicators of mitochondrial respiration and glycolysis. Results: scRNAseq reveal Hmga1 represses gene networks involved in oxidative phosphorylation (OXPHOS), including genes associated with the electron transport chain. Similarly, ChIPseq showed that HMGA1 binds promoter and enhancer regions of OXPHOS genes, suggesting that HMGA1 directly represses their expression. By Seahorse assays, mitochondrial respiration is repressed in murine HSPCs with intact HMGA1, whereas mitochondrial respiration is activated in HSPCs lacking HMGA1. By contrast, glycolytic capacity and reserve remain unchanged. Conclusions: Together, our studies unveil HMGA1 as a novel regulator of HSC metabolism by repressing OXPHOS genetic programs to restrict mitochondrial activity. Because mitochondrial activity and OXPHOS are associated with HSC cycling and differentiation, our results suggest that HMGA1 maintains HSC quiescence. Future studies will investigate whether modulating HMGA1 could enhance HSC function for stem cell transplantation and regenerative medicine.

Abstract Name: Translating Glassblowing Into Print: A Visual Identity for New Glass Now

This project was developed as an informational package for the Smithsonian's New Glass Now exhibition,

highlighting contemporary innovation in glass art. The guiding question behind my work was: How can a cohesive visual identity and its application help museum visitors better understand the fluidity, materiality, and creative process behind contemporary glass? To explore this, I researched the history and craft of glass blowing, studied museum publications, and experimented with materials and typography to translate the physical qualities of glass into graphic form. My methods were technical and experimental. I began by creating a custom typeface using chocolate sauce to mimic fluid motion, using its unpredictability as a metaphor for molten glass. This early experiment established the project's visual language: motion, translucency, and energy. From there, I developed gradients, layered shapes, and abstract forms inspired by how glass captures and refracts light. I also tested a variety of print materials, including holographic sticker paper, acetate, and metallic-coated paper, to understand how physical finishes could enhance luminosity and tactility on the page. The final package, which includes a museum catalog, donor card, educational booklet, and sticker pack, demonstrates how graphic design can make an unfamiliar craft, like glass blowing, feel more approachable to museum visitors. By mirroring the behavior of glass, the visual identity gives readers a tactile, intuitive sense of how the material feels. The material choices and immersive layouts work together to translate the complex, hands-on art of glassblowing into a visual experience that feels approachable.

Abstract Name: Understanding the Impact of Experiential Learning Through: Evidence from a Stock Pitch Competition

This study aims to assess the outcomes of an experiential learning opportunity, specifically a stock pitch competition. The benefits of experiential learning in academic settings are well-documented (e.g., Burch et al., 2019; Mak et al., 2017) and have been explored across various disciplines, including chemistry and accounting (e.g., Hulaikah et al., 2020; Alkan, 2016). Research within finance has also examined experiential learning through simulations, investment funds, and personal finance initiatives (e.g., Marriott et al., 2015; Bakoush, 2022; Dolan & Stevens, 2010; Brau et al., 2015). Despite the extensive literature on experiential learning, limited research exists on its application in stock pitch competitions, particularly regarding how to measure and quantify these outcomes. While experiential learning is widely acknowledged as valuable, this study seeks to evaluate its true impact and understand the significance of its benefits within the context of a stock pitch competition. Data will be collected from the inaugural stock pitch competition held last fall, in which 20 teams from the Huntsman School of Business participated. The study may also include students who participated in other stock pitch competitions, such as the William & Mary Women's Stock Pitch Competition and the Rocky Mountain Investment Challenge. A student researcher will conduct interviews with willing team members to gather qualitative data, which will be analyzed using a qualitative or mixed-methods approach. Findings from this research will inform the development of a survey, which will be distributed to students participating in future stock pitch competitions to further explore and measure the effects of experiential learning in this context.

Abstract Name: Safe Surfing: Moral Considerations on Children and Pornography

This paper is a consideration of moral perspectives regarding age verification laws and pornography. In 2023, the regional intercollegiate ethics bowl case described the situation in which select states in America began to require more stringent age verification on pornography websites. Previously, in order to comply with the laws, most sites utilize a system simply requiring users to check a box verifying their status as eighteen years old or older. Compliance with the new laws necessitates sites requiring users to upload their ID in order to more effectively verify their age. In response, some sites like Pornhub have merely declined to allow access to their sites in states requiring the new system of ID uploading. While there are many interesting questions to analyze in a case such as this, the following question is the focus of this paper: are children harmed by viewing pornography? The goal of this paper is to develop an effective argument through specific considerations of details in order to come to a decisive, moral, and philosophical conclusion. While alternative views are considered, and subsequently thrown out, the paper comes to the final conclusion in which pornography is, in fact, harmful to children.

Abstract Name: Prowling Unseen: Lost and Misattributed Cat Art by Women Artists

Cats have long been beloved subjects in art, yet the contributions of women artists who depicted them have frequently been erased, marginalized, or misattributed to male peers. In this research project I seek to recover these overlooked works by examining how gender biases in art history have systematically obscured women's legacies in animal representation. By analyzing case studies of lost, anonymized, or wrongly credited cat-themed art by women, this paper will argue that such exclusions reflect broader patterns of gendered dismissal, particularly the devaluation of "decorative" or "domestic" subjects. Reclaiming these works not only corrects the historical record but also challenges traditional narratives of artistic authority and creativity. Research questions I would like to explore through my investigation would include, How and why were cat-themed works by women artists excluded from canonical art history? What role did gender stereotypes play in their erasure? And how does rediscovering these works reshape understandings of animal representation and women's artistic labor? The methodology I would follow while investigating this topic would start with archival research, such as scrutinizing exhibition records, auction catalogs, and artist correspondence to identify overlooked or misattributed works that could make up an exhibition. I will be looking at feminist art historical frameworks. I will do this by applying theories by Griselda Pollock, on gendered space, and Linda Nochlin, on institutional exclusion, to interrogate systemic biases. This project rectifies historical emissions by centering women's contributions to animal art, demonstrating how "minor" subjects reflect major institutional biases. Along with highlighting the beauty of the feminine and the feline. By merging rigorous scholarship with public engagement and simultaneously leveraging the enduring appeal of cats, it advocates for a more inclusive art historiography, one that prowls beyond the canonical to uncover what has been unseen.

Abstract Name: The Protective Factor of Social Support on Exposure to Community Violence and Physical Aggression in Adolescents

Community violence (CV), defined as deliberate acts intended to cause physical harm within a community, disproportionately affects adolescents living in urban and marginalized areas (Cooley et al., 1995). African Americans are more likely to live in these environments due to historic inequities, resulting in higher rates of CV exposure. It is estimated that roughly 80% of adolescents living in urban communities have experienced or witnessed community violence (Pittman & Farrell, 2022). Victimization involves being the target of violence, while witnessing refers to the observation of violence towards others. In high-violence areas, these will likely coexist (Farrell et al., 2014). Social support from caregivers and peers has been identified as a potential moderator between CV and physical aggression; however, findings have been mixed (Coleman et al., 2023). To address this gap, this study examined the role of social and peer support as a protective factor for the association between community violence and aggression among African American adolescents. The sample included 221 African American adolescents (ages 12-17, 51% female) living in three urban low-income communities. Regression analysis indicated that: (1) violence victimization was significantly associated with high frequency of physical aggression ($\beta = 0.57$, $SE = 0.06$, $p < .001$), (2) witnessing violence was significantly associated with higher levels of physical aggression ($\beta = 0.54$, $SE = 0.04$, $p < .001$), (3) neither social support measure (i.e., adult role model or community support) showed a significant protective effect. These findings indicate that there is a positive association between both victimization and witnessing community violence and physical aggression among African American adolescents. Further research is needed to identify protective factors that can mitigate this relationship and better support youth exposed to community violence.

Abstract Name: Simulating Power Production for JMU East Campus Solar Facility

Solar photovoltaic (PV) energy production has seen rapid development in Virginia. However, unlike traditional fossil fuel-based energy sources, solar PV energy production is heavily impacted by weather conditions and the efficiency of the energy system. As a result, solar PV energy production is typically associated with a higher volatility and the production peak might not overlap with the peak of consumption. It's important to understand the energy production of a system and how well it is performing under constantly changing conditions. In this project, we ask the question: How closely can we simulate solar PV energy production? We are interested in studying the predictability of solar photovoltaic energy production using the on-site solar array system at JMU's East Campus solar facility. We used an industrial standard software to study how well we can simulate solar photovoltaic energy production and then compared it to the collected data. To simulate power production from the solar facility at JMU, we used a cloud-based system developed by Terabase called PlantPredict. PlantPredict allowed us to run a Block-by-Block simulation where we first, create our solar facility with precision by constructing each array, inverter, and DC Field following JMU's blueprints. Lastly, we used Solcast API to acquire Historical Time Series weather data across the year. With this information we can run a simulation through PlantPredict and then verify with JMU's solar facility. We found that applying a 15% wiring loss to the simulation brought our Bias close to zero while lowering our RMSE. This indicates that PlantPredict approximates a 15% loss of energy due to the wiring design in JMU's solar facility.

Abstract Name: Using User-Collected Hormone Data to Model Luteal Phase Progesterone Dynamics

Understanding hormone patterns during the luteal phase of the menstrual cycle is necessary for determining normal menstrual physiology and identifying symptoms that may point to polycystic ovary syndrome (PCOS). Most studies on PCOS focus on single-day measurements or broad cycle length statistics. New cycle tracking technologies allow for daily hormone sampling across different populations. This project uses user-collected hormone data from the fertility app Mira to evaluate whether machine-learning can provide a more accurate way to study progesterone (PDG) rise. I analyzed three linked datasets: a hormone-level dataset containing daily estrogen (E3G), luteinizing hormone (LH), and progesterone (PDG), a cycle-level dataset containing cycle length, and derived summary hormone features, and an individual-level dataset containing disease status (PCOS vs. healthy controls), number of cycles recorded, and overall regularity of cycle length. For each cycle, each day is also mapped to one of six defined cycle phases using a hidden Markov model (HMM). For each cycle, I computed the mean PDG in two important windows: cycle days 19-22 which is typically the post-ovulation PDG rise and cycle phase 5, which corresponds to the same window, but allows for variation in cycle timing. I also calculated ratios of PDG levels for these windows compared to a baseline level for each cycle. Preliminary results show PDG levels differ by cycle regularity and PCOS status. Boxplots suggest that phase 5 shows a stronger PDG rise than days 19-22 across most groups. This shows that only using cycle days may miss individualized hormone rises. I also used a paired t-test comparing days 19-22 vs. phase 5. This also showed that the HMM model may reveal more accurate hormone transitions. Additionally, normal length cycles (24-33 days) show tighter ratio distributions, whereas irregular cycles exhibit broader variability.

Abstract Name: From Pocahontas to Tiger Lilly: The Role of Colonial Sexual Propaganda in Contemporary Native American Exploitation.

Sexual conquest and colonization performed in the name of Christianity have continually exploited Native American women. Continuously, European colonial powers have been used to create forms of inequity that have affected Indigenous women. From as early as the 16th century, images of "The New World" were produced. One would either see the "evil" Indigenous woman naked holding the head of a white settler, or an attractive woman sitting on top of food and gold. The former image represented a woman in desperate need of Christianity, while the latter represented the fertility of the land, its resources, and the women themselves. Both of these images were used as strategic tools in sexual conquest and colonization. In addition, the 1605 English Comedy "Eastward Ho!" depicts a fantasy of sexually colonizing Native American women and producing "English faced children." This colonial rhetoric was carefully constructed propaganda to sexualize

Native Women to encourage settlers to come to “The New World.” In the present day, Native American women experience the highest levels of sexual violence of any racial group in The United States. This interpretive work examines Christian colonial ideas and how such ideas contributed to the exploitation of Native women. This research uses comparative work of both primary and secondary sources through a feminist and queer studies research approach that considers intersectionality and cultural constructions. The results of this research reinterpret Christian colonial rhetoric that allow for a clearer understanding of the modern view of Native American women and the inequities they face.

Abstract Name: Growing up Working: Impression Management and Motivation in High-Achieving Generation Z Students

The aim of this research is to investigate the motivations for self-defined achievement among Generation Z college students and how they are socialized to portray the image of hegemonic success. Prior scholarship on this topic has applied Goffman’s impression management, Cooley’s looking glass self, and social identity theory to frame and interpret the ways college students develop and express work habits as they transition into their careers. In previously conducted research, we found that high achieving students in college internalize many external pressures while upholding individually imposed standards of self-representation. For “traditional” full-time students who are also employed, this may result in imposter syndrome, burnout, and in some cases, dissociation and detachment from their own work behaviors and attitudes. By conducting open-ended, semi-structured interviews with full-time college students who are also working, we aim to understand and conceptualize their “working selves”, their work routines, and the extent to which failure and/or achievement motivates both. Using a thematic approach focused on categories such as school, work, wellbeing/happiness, and the social lives of the participants, we investigate the catalysts for the routines and actions expressed in this group. Through understanding their backstage habits and contexts, we also look for underlying mechanisms and embedded practices stemming from the influence of the individual students’ various social networks. We aim to address the following questions in this study: First, what strategies do students use to stay “productive” in their work according to their own standards? Second, how do these practices affect college students’ sense of wellbeing and achievement? Third, which social factors and contextual aspects are most crucial in determining each individual’s work ethic?

Abstract Name: Calculated Negotiations: Fray Motolinía’s Capitalization of Tetzcocan Authority and Customs

The first friars sent to New Spain had royal orders to evangelize the “infidels” of the territory in order to prepare for the Second Coming of Christ. Accomplishing this mass conversion required Spanish missionaries, such as Franciscan friar Toribio de Benavente Motolinía, to depend on previously established native systems

of governance. Yet, Motolinía did not regard the strength of native governments as a hindrance to King Charles V's authority over the Americas. On the contrary, Motolinía viewed these systems as a key aspect in facilitating the Spanish conquest, and he even regarded the sophistication of Tetzcoacan institutions as a divine portent. Scholars such as Sanjay Subrahmanyam and Geoffrey Parker have demonstrated how apocalyptic optimism was a fundamental underpinning of arguments of Spanish claim over the Americas, while Nicole T. Hughes has emphasized that the early Franciscans, including Motolinía, viewed Indigenous institutions positively and even believed they provided a superior basis for a future Christian state that would usher in the End Time. This essay analyzes Motolinía's 1555 Letter to Charles V as well as his Memoriales to show the significance he attached to the Acolhua nobility of Tetzcoaco in reinforcing the Spanish king's authority and contributing to the "consummation of the world" through Charles's divinely ordained kingship. By upholding Tetzcoacan customs, at times in opposition to other clerics like Bartolomé de las Casas, Motolinía crafted a view of America as a land that was superior to Spain and a more dependable instrument for upholding the king's power.

Abstract Name: Parental attitudes toward child therapy: Factors influencing opinions on art therapy versus traditional talk therapy

Art therapy has gained recognition as a powerful tool for helping children express and process emotions. Even though research has shown its benefits, less is known about how parents perceive art therapy compared to more conventional approaches, such as talk therapy, for their children. Parents play a central role in choosing the type of therapy their children receive, and their attitudes, past experiences, and beliefs can significantly shape these decisions (Nevás & Farber, 2001). The current study is exploratory in nature and examines parental perceptions of art therapy and traditional talk therapy, and investigates factors influencing these attitudes. Specifically, the goal of the present study is to determine how parents' experiences with therapy, opinions about therapy, and engagement with art relate to their openness to seeking therapy for their children and to alternative therapeutic approaches. We hypothesize that parents will view traditional talk therapy as more effective, that prior therapy experience and higher personal art engagement will increase openness to therapy and alternative approaches, and that parents willing to seek help for themselves will be more likely to support their children undergoing therapy. Participants are parents aged 18+ with at least one child aged 4-17. Data is being collected through a 20-minute online anonymous survey, including questions on demographics, past therapeutic experiences, attitudes toward seeking mental health support, engagement with art, perceived effectiveness of art and talk therapy, and willingness to have their child participate in either therapy. Results are expected by January 1, 2026. Findings may inform strategies for increasing engagement with both traditional and nontraditional mental health interventions and support parents in making informed decisions that benefit their children's emotional and behavioral well-being.

Abstract Name: In Lieu of a Plaza: Exploring Urban Vitality on Sidewalks in the Northeast Los Angeles

Neighborhood of Highland Park

The issue of public space has been long discussed and debated in Los Angeles. Across cultures and continents, plazas and other such central public spaces, have historically served as meeting points for public, urban life (Wagner et al., 2013). But because of L.A.'s unique history of development—Los Angeles developed as a sprawling city without a walkable urban core—and because of increasing pressures of privatization, Los Angeles has not been conducive to public, open spaces such as these (Scott & Soja, 1996; Davis, 1990). This has made sidewalks incredibly important public spaces for urban life in Los Angeles. In this case study, I examine two streets in the Highland Park neighborhood of Los Angeles to explore if, where, and how urban vitality—which I assert includes both commercial activity and human interaction—shows up on sidewalks. Through a combination of participant observation and surveys at my two sites, my research reveals that most activity on the sidewalk is directly or indirectly related to businesses on the street, essentially privatizing the public right-of-way that is the sidewalk. Despite the privatization of this public space—a long-standing tradition in Los Angeles—I find that people still manage to bring activity and vibrance to the sidewalk through street vending, creation and use of informal seating, and use of open space for events like farmers markets and concerts. These findings have implications for the City of Los Angeles, as they emphasize the importance of infrastructure and policies around sidewalk seating, street vending and the pedestrian experience. More widely, this study aims to illuminate the value of accessible, truly public space in urban landscapes—with or without traditional plazas.

Abstract Name: The Graduate Divide: Gender and Socioeconomic

This study examines how socioeconomic status (SES) influences high school students' expectations of completing a graduate degree, with particular attention to gender differences. Building on existing research showing that both SES and gender shape educational trajectories, this project analyzes patterns in academic aspirations among 9th graders using data from the High School Longitudinal Study of 2009 (HSL:09). Educational expectations vary significantly by both gender and SES, and a chi-square test confirms this relationship is statistically significant for males and females. Higher-SES students are substantially more likely to expect to pursue advanced degrees, while lower-SES students more often anticipate completing only a high school diploma. Gender differences also emerge that female students in upper SES groups report stronger expectations for earning graduate degrees, whereas males in the highest SES group are more likely to anticipate pursuing a Ph.D. These findings reinforce prior evidence that SES, gender, and related factors such as self-efficacy and mentoring shape long-term educational goals. Overall, this research highlights persistent inequities in graduate-level aspirations and underscores the importance of targeted supports and equitable resources to expand pathways to advanced education.

Abstract Name: Effect of Tuning Chemical Composition on Tensile Strength of Refractory Multi-Component Alloys

Refractory multi-component alloys exhibit high strength, heat resistance, corrosion resistance and can find applications in aerospace, energy production, and security industries. Investigation of multi-component alloys typically relies on equiatomic compositions leaving vast unexplored chemical spaces. Equiatomic alloys have roughly equal atomic concentrations which promote stable configurations. This study is part of a broader project that uses thermodynamic principles to explore behavior of non equiatomic, refractory compositionally complex alloys. Starting from a Hafnium, Niobium, Tantalum, Titanium, and Zirconium palette, a series of non-equiatomic, multi-component alloys is developed. Variations in chemical composition can affect phase type, phase stability and in turn mechanical properties. Understanding of mechanical response is important for structural applications; additionally, costs can be cut down by reducing the ratio of expensive elements while maintaining good structural performance. In this study, the effect of changing chemical composition is investigated, focusing on effects of hafnium depletion on phase stability and mechanical performance. Tensile specimens, manufactured by vacuum arc casting, are axially loaded using a tabletop mechanical testing system until rupture. Strains are measured using a Digital Image Correlation system (DIC). The non-contact technique involves a calibrated, stereoscopic two-camera setup for measurement of full field, three-dimensional displacements. A proprietary software subsequently computes strains across the sample surface. Matching DIC and tensile loading data, mechanical properties such as Young's modulus, yield stress, ultimate tensile strength, and failure strain are determined for complete elastic and plastic characterization. Crystal structure, investigated by x-ray diffraction, revealed all alloys consisted of a single BCC phase. Mechanical testing revealed that reduced niobium content and increased hafnium content leads to a reduction in strength.

Abstract Name: A Soft Robotic Fish for Mobile Detection of Aquatic Contaminants

Aquatic ecosystems are increasingly contaminated by endocrine-disrupting chemicals such as bisphenol-A (BPA), yet water-quality monitoring still relies largely on static sensors and periodic sampling that fail to capture spatial and temporal variability or locate contamination sources. To address this limitation, we developed a small, magnetically actuated, soft-bodied robotic fish for low-noise propulsion, in situ chemical sensing, and autonomous source seeking. The robot employs an electromagnetic tail-fin actuator composed of a solenoid, an oscillating drive signal, and two opposing permanent magnets embedded within a molded silicone body, producing an ostraciiform-like swimming gait similar to that of boxfish. Building on this platform, we integrated a plasmonic BPA sensor within the biomimetic body and tail and a micro-pump buoyancy control system based on a bio-inspired elastic bladder, all coordinated by an onboard microcontroller. Experimental tests in controlled aquatic environments demonstrated stable, low-noise oscillatory tail motion, efficient propulsion, and flow fields comparable to those generated by real fish, while enabling real-time plasmonic detection of BPA. By coupling the plasmonic sensor output to onboard control, the robotic fish successfully followed increasing BPA concentration gradients and localized point sources of contamination in test tanks, demonstrating a form of environmental chemotaxis. Because the plasmonic sensing elements can be functionalized for different analytes, the same architecture is adaptable to other pollutants, including heavy metals and additional endocrine disruptors. These results highlight magnetically

actuated soft robotic fish as a versatile, minimally invasive platform for mobile environmental monitoring, chemical plume tracking, and source localization in contaminated aquatic ecosystems.

Abstract Name: Generation to Generation: Conversing with Kindred Technologies

Generation to Generation: Conversing with Kindred Technologies explores how humans and technology have always evolved together. This immersive, traveling art exhibition blends the past, present, and future of technology and language through physical, digital, and written media. Inviting viewers to consider their relationships and attitudes towards current and emerging technologies, this show and catalog act as both an action and a call to action. Generation to Generation provokes a reflection on how technology both enhances and evolves our understandings of politics and society, matter and nature, and our world and ourselves. New technologies - with Artificial Intelligence being the latest and most rapid form - should induce neither blind optimism, nor crippling fear. AI, for example, continues to rapidly progress and improve, and Generation 2 Generation encourages discourse about its place in our personal lives, relationships, and broader society. The unifying element of a font created by AI creates an aesthetic that challenges technology itself. Asking and answering these questions has seen the production of a monumental, poetic landscape of reclaimed electronic waste; an interactive mirror that “reads” human movement and translates it into dynamic code; a print- and image-based installation, featuring a custom AI font that evolves past human understanding, beyond the limits of the screen or page; play-based installation of stencils, coloring books, and paint; concrete poetry made of precious metals recovered from mining slag and computer waste — alchemized artifacts of digital communication; and, media-rich (generative/oral/aural/digital) performances of AI-powered poetry, updating an ancient art form for the approaching posthuman age. Neural Networks, as well as novel understandings of natural networks, are enabling and enhancing unique forms of creative exploration in and with various matter and materials, life and non-life. Generation to Generation hopes to open up those spaces for even greater exploration.

Abstract Name: Mitochondrial Dysfunction and Cognitive Impairment in Sepsis Survivor Mice

Sepsis is a potentially fatal systemic response to infection in the body. A majority of sepsis survivors

experience a condition known as post-sepsis syndrome (PSS) including physical and cognitive impairment. Previously we developed a mouse PSS model in which sepsis surviving mice demonstrate long-term muscle weakness accompanied with mitochondrial dysfunction. The objectives of the current study were to 1) examine whether our PSS model also exhibits cognitive impairment and 2) identify potential causes of cognitive impairment after sepsis. Sepsis was induced by abdominal infection followed by repeated antibiotics treatment and fluid resuscitation beginning 12 hours later. Fear conditioning memory tests were performed on both sepsis survivor and control mice three to four weeks after sepsis induction. Five weeks after sepsis induction, hippocampus tissues were collected for gene expression profiling by bulk RNA sequencing analysis. Results of the fear conditioning tests showed significant memory impairment in sepsis survivor mice. RNA sequencing analysis followed by Gene Ontology (GO) pathway analyses revealed significant differences between sepsis survivor and control mice. The top five most up-regulated gene pathways in sepsis survivors were all related to neuronal cell growth while the top five most down-regulated gene pathways included four mitochondrial respiration related pathways and one ribosomal translation pathway. Five out of 13 mitochondria-encoded protein-coding genes were also down-regulated suggesting mitochondrial damage and dysfunction. These ongoing analyses suggest that sepsis survivor mice have long-term cognitive impairment which involves reduced mitochondrial and ribosomal functions with altered synaptic cell growth in the hippocampus.

Abstract Name: Enabling Health Monitoring in Extreme Environments: A Low-Power Electrocardiogram System for Wearable Applications

Wearable physiological sensors are increasingly used to monitor health and performance in extreme environments, such as spaceflight or the Arctic. Electrocardiogram (ECG), which measures electrical activity of the heart, is one of the most prominent physiological sensors due to its well-characterized dynamics and broad diagnostic utility. However, reliably acquiring and storing high-quality ECG signals in these environments remains challenging due to strict power constraints. This project investigates the design and evaluation of a low-power, microcontroller-based ECG acquisition and data-logging system suitable for integration into wearable systems used in extreme environments. The first phase of development focused on characterizing ECG signal amplification using the INA333 instrumentation amplifier, a device previously implemented in similar environments. A test setup consisting of an Arduino Uno R3, solderless breadboard, and 4-GB microSD card interface was used to evaluate analog signal integrity, supported by firmware that logged raw ECG data for offline analysis. Although the INA333 is extremely low power (50 μ A), its sole function is signal amplification, making it poorly suited for ECG acquisition. In contrast, the MAX30003 biopotential chip draws similar power (85 μ A) while integrating noise-reduction circuitry, digital filtering, and an architecture optimized for ECG acquisition. Thus, it was selected for continued development. Open-source pinouts and logging software were adapted into the existing system architecture, and the breadboard prototype is currently being translated into an Electronic-CAD design to enable the fabrication of a printed circuit board (PCB). This PCB will later be integrated into a chest strap form factor for ECG data collection. Future work will focus on software enhancements, including an on-device data compression algorithm to extend storage capacity, and a machine learning-based ECG analysis tool for improved denoising and analysis. Together, these developments aim to advance high quality, user-friendly, and low-power wearable ECG systems capable of reliable operation in extreme environments.

Abstract Name: Developing a Self-driving RC Car

This project develops a self-driving remote-controlled (RC) car as an affordable and accessible educational tool for learning about autonomous vehicle technology. While self-driving cars are becoming increasingly important in modern transportation, opportunities for students to gain hands-on experience in this field are still limited. While development platforms such as DonkeyCar and Robot Operating System (ROS) exist, these are generalized tools that work with many hardware platforms and can be difficult for beginners. We created a detailed guide and code base to help new users get started with self-driving cars. We utilized DonkeyCar, an open-source platform that supports both traditional computer vision and deep learning-based driving methods. It also includes a simulated environment to train and test models independently of hardware. Our key challenges using DonkeyCar were hardware compatibility, software configuration, and sensor calibration. Our guide addresses these issues and provides a single source to get new users started with self-driving cars. Beyond the creation of a guide, we developed a self-driving car ourselves. Our approach included training driving models in a simulated environment before applying them to physical hardware. We selected and configured a Waveshare PiRacer Pro, which is a Raspberry Pi-based RC car. We trained a neural network to imitate human driving by learning from camera images and corresponding steering inputs. This method can successfully navigate a simple track, and we expect that, given additional and varied data, it can navigate more complex environments. We also implemented a simpler, rule-based system that uses color and edge detection to follow lines on a track. Future work will focus on improving adaptability by combining multiple control methods and integrating additional sensors. This project provides a practical, scalable foundation for students and educators interested in robotics, artificial intelligence, and autonomous systems.

Abstract Name: An Analysis of Various Storm Environments during a Field Course in Extreme Weather, Summer 2025

This study examines the environmental characteristics and atmospheric dynamics associated with various thunderstorm morphologies observed during the Forecasting and Verification of Extreme Weather field course. The course took place in the summer of 2025 across the Great Plains region of the United States. Thunderstorms and their associated hazards, including hail, straight-line winds, tornadoes, flooding, and derechos, arise from a combination of atmospheric ingredients present at the right time. The objective of this research is to identify the specific combinations of moisture, lift, instability, and shear that differentiate storm types and influence associated hazards. Data was collected through a combination of in situ observations, radar, satellite imagery, and archived datasets from the National Weather Service and the Storm Prediction Center. In-depth discussion surrounds three events that produced significant severe hazards: 5-inch hail, 13 landspout tornadoes, and a large wedge tornado. By comparing the atmospheric environments associated with each storm type, this research contributes to a deeper understanding of convective processes and the predictability of severe weather within the mid-latitude continental United States.

Abstract Name: The Diversity of West Caribbean Octocorals in Roatán, Honduras

Sea fans, rods, and whips, known as octocorals, serve vital functions in tropical marine ecosystems, providing habitats and supporting biodiversity. Current research regarding Caribbean octocorals is limited as research in the tropics has primarily focused on the threatened scleractinian coral populations. A renewed interest in octocoral research has been stimulated by anthropogenic needs, as Octocorallia exhibits promising results for new natural marine products. Ecological surveys suggest octocorals provide necessary insight into the health of the reefs in response to environmental disruptions from climate change, industry, and disease. This study was conducted to assess the diversity and health of octocoral communities in Western Caribbean shallow reefs in Roatán, Honduras. Divers conducted belt transects at four established dive sites along the Mesoamerican Barrier Reef and enumerated specimens by species. At each site: species were evaluated for density per meter squared and sites analyzed through Gini-Simpson's Diversity Indices, and Simpson's Evenness. This study identified 19 species across 9 genera: Antillogorgia, Briareum, Eunicea, Gorgonia, Muricea, Muriceopsis, Plexaura, Plexaurella, Pseudoplexaura, and Pterogorgia. The most common species identified in order of prevalence were: Antillogorgia americana, A. bipinnata, Briareum asbestinum, Gorgonia flabellum, Eunicea calyculata. Researchers noted differential community compositions between spur-and-groove formations and patch reef formations, but Chi-Square Test revealed no statistical significances between site richness, diversity, evenness, or density. Diversity was comparable to surveys conducted on Saba Bank, Nederland Antilles. Low disease incidence along transects prevented any analyses regarding health. Continued and extensive monitoring is recommended. Additional sample sites, genetic and microscopic analyses, and presence/absence surveys are expected to provide the most insight to community composition. Researchers also recommend the modification of the conducted methodology to include analyses by depth and substrate.

Abstract Name: The Effect of D-Glucose on Solubility and Fluorescence of Riboflavin

The purpose of this research is to determine an effective way to make riboflavin (Rf), also known as vitamin B2, more soluble in water while retaining its important fluorescence activity. Rf is only partially soluble in water, and while it dissolves in bases, this solvent quenches Rf's fluorescence. Current published methods for making Rf more soluble, such as DMSO recrystallization or dissolution in various organic solvents, do not focus on retaining fluorescence. Fluorescence is widely used in medical imaging, and Rf is a safe choice for

fluorescence due to its high safety profile. Rf has been proven to be a superior tracer in aerosol contamination models due to its reliable fluorescence, has been used as a medicine compliance tracker, and has been used in contact contamination trials. Making Rf more water soluble will expand its medical uses to allow it to be used in place of more hazardous substances such as Fluorescein. In order to create more soluble Rf, we tested suspension solutions, and determined that they were effective for retaining fluorescence until the suspensions dried or the Rf precipitates over time. We then tested various saturated sugar solutions due to saccharides' high solubility in water and the idea that saturated sugar solutions increase viscosity of water. We found sugars increased solubility of Rf water based solutions without quenching fluorescence. Furthermore, we found that D-glucose significantly enhanced fluorescence when measured with a fluorometer. To determine molecular interactions between the D-glucose, Rf, and water solutions, we measured the D-glucose sample with common analytical techniques, such as IR spectroscopy. We also investigated recrystallization using different solvents to attempt to improve solubility while retaining Rf's fluorescence while in solution.

Abstract Name: Rapid Fatigue Categorization of Metal Alloys

The advent of additive manufacturing (AM) processes for metals and alloys has opened up a new field of material research and alloy composition optimization. In particular, it has enabled the production of multimaterial parts by mixing metallic powders during the printing process. While material manufacturing capabilities have advanced, material testing capabilities have not caught up. An essential requirement of categorizing these AM materials is predicting their fatigue behavior. Fatigue is the result of the repeated cyclic loading of a material over time. Failure due to fatigue has been estimated as the most common failure mode in mechanical components. The traditional, time intensive method of fatigue categorization requires multiple dogbone specimens to be cyclically loaded to develop a stress-life design curve (S-N Curve). Modern methods such as Digital Image Correlation (DIC), an optical method for measuring full field strains, has grown in popularity for fatigue categorization of metals. Utilizing DIC our team has developed an expedited process for stress-life categorization, compatible with industry standard test and manufacturing equipment. A novel test coupon designed with six potential failure points was cyclically loaded in an MTS test frame, with local strains measured via a Correlated Solutions stereo DIC system. Alloys of known material properties were tested and compared to published handbook data. The fatigue curve developed via the novel geometry, exhibits consistency with literature data, with as little as three test coupons, over six days of testing. We plan to turn this method into a material standard for fatigue categorization of metals. Future areas of testing this coupon geometry include high temperature fatigue, creep, and crack growth categorization.

Abstract Name: Family Functioning and Children's Appraisals of Threat and Security Amidst the COVID-19 Pandemic

Children's interpretations of stressful events play a role in shaping their emotional and behavioral adjustment, making it essential to understand the factors that influence how children evaluate danger and safety. Previous research identified associations between family processes and child adjustment (Zhang et al., 2025), and between family functioning and children's sense of safety (Berger & Font, 2019), yet it is unclear how dimensions of the family environment relate to children's threat and security appraisals (i.e., cognitive evaluations of danger, safety, and security). This study focuses on whether aspects of family functioning are associated with how threatened or secure children felt regarding the COVID-19 pandemic. I hypothesized

that higher cohesion, collective efficacy, and problem solving in the family would be associated with lower perceived threat and higher perceived security in children. Cross-sectional data were collected from 89 U.S. parent-child dyads in 2021, during the COVID-19 pandemic. The study was approved by the IRB. Following consent and assent, children reported their threat and security appraisals (Child Threat Appraisals COVID-19 Scale) and parents reported family group cohesion (COVID-19 Household Environment Scale), collective efficacy (Family Collective Efficacy Scale), and problem solving (Family Problem Solving Communication Scale). Correlations will be conducted to evaluate associations between each family environment subscale and threat and security appraisal. Analyses are ongoing, but preliminary results show statistically significant associations between aspects of family functioning and children's appraisals ($p < .05$). Results align with family stress perspectives (e.g., Zhang et al., 2025) which suggest that children in more supportive and connected family systems interpret stressful events as less threatening. Results could help clarify which specific family components shape children's perceptions of safety. Such work has implications for prevention/ intervention programs aimed at assisting children and families facing stressful events and circumstances.

Abstract Name: Translating María Zambrano's *The Tomb of Antigone*

As an exploration into the art of literary translation, this project endeavors to create the first complete English translation of María Zambrano's play *The Tomb of Antigone* (*La tumba de Antígona*, 1967). In this play-essay hybrid, Zambrano opens a philosophical dialogue with Sophocles to offer a new interpretation of his Greek tragedy while simultaneously illustrating her own experiences and ideas surrounding the Spanish Civil War. Using her philosophical construct of delirium, Zambrano creates Antigone's stream of consciousness as she waits for her inevitable death. As the text demonstrates originality in its interweaving of genres to discuss the issues of Zambrano's time, a translation of this work would foster new interpretations and discussions about Zambrano and Spanish culture with English-speaking scholars in both the philosophical and literary disciplines. To achieve this end, the mentor and student consulted various texts to understand the cultural, historical, and literary traditions of Spain during the time Zambrano was writing, as well as the author herself, which led to the translation of the play's prologue. The twelve-part play was then split into four sections that will be translated over the course of two weeks, after which the mentor and student will convene to discuss the draft. Once the rough draft is complete, both the student and mentor will review and revise to create a more polished version. This project will result in a polished draft of the translation that will be sent to the María Zambrano Foundation in Vélez-Málaga to obtain permission to seek an academic publisher.

Abstract Name: *Creating a Predator: Intersectional Paradoxes of Oppression Within Trans-Exclusive Lesbian Feminisms*

In the 1970s, lesbian-feminist communities in the United States of America struggled to integrate the complexities of the intersectionality of gender and sexuality. The nature of this relationship is inextricably interlinked with the search for a nonmedicalized and empowering lesbian identity, which was a prevalent topic during the peak of lesbian-feminism in response to centuries of lesbian erasure and criminalized homosexuality. Rather than focusing all efforts on confronting oppressive institutional and social structures that rendered them psychologically perverse, extremist lesbian feminists created a new enemy, popularizing a demonized representation of transgender women as “aggressive sexual predators” that infiltrated national discourse. In part, transphobic lesbian-identified individuals collectively heightened their social standing through further oppressing transgender individuals, reproducing the same systems that once rendered them marginalized through the othering of individuals whom they once shared oppressive status with. However, the majority of lesbian organizations with transgender exclusive policies inspired division between marginalized groups, empowered anti-LGBTQ+ rhetoric further, and cultivated their own downfall. The attempted methods of liberation used by these extremist groups perpetuate a one-dimensional understanding of multiple systems of domination that have historically impacted all LGBTQ+ individuals. I argue that this single-axis framework contributed to the foundation of contemporary transphobic policies, conversations, and ideologies that label transgender women as sexual predators and aided in the empowerment of anti-LGBTQ+ structures. This research employs an intersectional analysis of trans-exclusionary lesbian-feminist involvement in framing contemporary depictions of transgender women as predatory, which ultimately further disempowers the entirety of the LGBTQ+ community. Research methods utilize an intersectional framework in integrating comparative historiographical analyses of secondary and primary literature reviews and oral history. This research contributes to broader discussions of intersectional theory, transgender and lesbian history, and studies on the paradox of oppression

Abstract Name: Reported Experiences in Collegiate Track and Field and Cross Country Athletes

Athletes who reach the collegiate level face a wide range of sporting experiences. Track & field and cross-country athletes in particular have unique qualities given the unique practice style and independent nature of competition. In addition to the nature of these sports, the different team atmospheres and the fact that athletes perform individually are important aspects to consider when doing research in this area. To date, limited work has examined the potential differences in motivation between track & field and cross-country athletes who score and those who do not score— we completed this research to help address this gap. In addition, we were interested in mirroring previous research by examining the predictive value of accountability (Witvliet et al., 2019) on flourishing (Keyes et al., 2002). We addressed the gaps in the literature by having collegiate track & field and cross-country athletes across a range of divisions and schools complete established measures of burnout, athlete orientation (Task, Ego), accountability, flourishing, and sport competence. The purpose of our study was two-fold: 1) To provide a descriptive account of how scoring status links to accountability, and 2) to identify whether accountability can predict flourishing above and beyond self-reported burnout and athlete orientation scores. 101 collegiate athletes completed a 10-minute survey assessing the variables of interest. An Independent T-test showed scores ($M = 66.15$, $SD = 8.17$) and non-scorers ($M = 63.57$, $SD = 8.84$) did not differ in reported Flourishing scores ($t(99) = 1.52$, $p > .05$). Hierarchical regressions were run to examine whether the Accountability scale predicts Flourishing. Accountability scores (Step 3) did not go beyond Athlete Orientation (Step 2: Task & Ego) and Burnout scores (Step 1: Exhaustion, Devaluation, & Reduced Accomplishment) to account for significant additional variance in Flourishing. Future work should examine the relevance of sport type.

Abstract Name: Sacred, Secular, and the Sounds of Conflict: A Comparative Study of Leonard Bernstein's Mass and Benjamin Britten's War Requiem

Leonard Bernstein's Mass (1971) and Benjamin Britten's War Requiem (1962) are two of the twentieth century's most profound musical meditations on faith, conscience, and the moral responsibilities of art. Both composers turned to the Latin Mass not as a static form of inherited devotion but as a flexible framework through which to explore the intersections of ritual, belief, and modern ethical awareness. Britten's requiem intertwines sacred liturgy with the war poetry of Wilfred Owen to mourn the devastation of conflict, while Bernstein's Mass stages a celebrant's unraveling faith as an emblem of spiritual crisis amid post-Vietnam disillusionment. This study draws on a diverse range of sources, including contemporaneous press clippings, composer correspondence and performance documents, FBI surveillance records, and critical scholarship in musicology, theology, and cultural history. Together, these materials situate both works within debates on pacifism, moral authority, and the composers' capacity to bear witness. Through comparative analysis of text, music, theatrical design, and reception, the paper examines how each composer transforms the Mass into a site of confrontation: Britten through the fusion of prayer and protest, Bernstein through the collision of liturgy and popular idiom. Ultimately, this study argues that the American reception of these works—rooted in pacifist conviction and ecumenical aspiration—reveals how both blurred the boundary between the sacred and the secular. By unsettling liturgical expectation and creating spaces of shared reflection, they emerged as cultural signposts through which mid-century audiences grappled with faith, modernity, and the search for moral meaning.

Abstract Name: Artificial Intelligence in the Advancement of Mechanical Circulatory Support: A Systematic Review of its Role and Potential

In recent years, there has been a notable surge in the ability of machines to perform complex and intelligent human-centered tasks, particularly within the domain of cardiovascular health. Transformative advancements in artificial intelligence (AI) and machine learning (ML) algorithms reflect the tremendous potential for such analyses to meaningfully extend into design, translational development, and clinical usage of medical devices, especially mechanical circulatory support (MCS) therapies. Here, we investigate and report the applications, limitations, and strategies in which AI is currently being employed in MCS and the potential opportunities of AI approaches to transform the field of MCS. To effectively assess the scope and impact of AI in MCS, we conducted a systematic literature review. A comprehensive search of 4 recognized research databases (PubMed, Google Scholar, Ovid MEDLINE, and ProQuest) was performed using this Boolean

string: “(Artificial Intelligence) AND (AI) AND (Mechanical Circulatory Support) AND (MCS) NOT (Heart Transplant) NOT (Cardiogenic Shock) NOT (Critical Care).” Most relevant publications covered the prediction and management of postoperative outcomes, and the development of personalized device-patient matching and timing. AI modeling has been instrumental in successful predictions of complications, recovery trajectories, and long-term survival. It has also been employed to inform clinical decision-making. Barriers to broad implementation of AI include the need for sizable, high-quality datasets to achieve algorithm training benchmarks, the lack of organized and incomplete databases, and limited computational resources. Emerging frontiers of MCS recognize the potential for AI and ML techniques to refine and improve image recognition capabilities, diagnostic assessment, device placement, and post-implantation monitoring approaches in the future. AI-driven advancements demonstrate a promising convergence of computational power and clinical expertise, offering personalized, efficient, and informed clinical management of MCS patients.

Abstract Name: Impact of Digital Reading Tools on Phonemic Awareness and Decoding Skills Among African American Students

Generation Alpha is the most exposed generation to technology, with digital tools deeply integrated into their everyday lives and learning experiences. Reading is the most fundamental skill for students' academic success, yet the ways in which students learn to read are rapidly changing. As the educational landscape increases its reliance on Digital Reading Tools (DRT), we must investigate how these tools influence the phonemic awareness and decoding skills of students. DRT, such as I-Ready, are platforms that are heavily used to support students' reading instruction. Research has proven that early and excessive exposure to digital educational tools can have lasting cognitive and developmental effects on children. Through a mixed-method approach, this research aims to explore how exposure to DRT influences phonemic awareness and decoding skills among African American kindergarten students. To examine the impact of digital reading tools, quantitatively I will collect student I-Ready assessment data from the beginning of the grading period and end of grading period. Qualitatively, I will observe students to examine if they display accurate phonemic awareness and decoding skills independent of the DRT. Through this data, I hope to find patterns regarding the impact of digital reading tools in the classroom.

Abstract Name: Developing an AI Prompt Library for Evidence-Based Exercise Prescription: A Microsoft Copilot Agent Evaluation Study

Artificial intelligence is increasingly prevalent in healthcare and fitness settings, yet lacks validated frameworks for safe, evidence-based exercise prescription. This gap poses risks when individuals rely on AI without professional oversight or proper prompting strategies. This study develops and validates a comprehensive AI prompt library enabling kinesiology professionals to prescribe evidence-based exercise

programs with AI assistance. Target populations include healthy adults, older adults, youth, and individuals with chronic conditions, incorporating FITT-VP principles and ACSM/CDC guidelines. We developed a Microsoft Copilot agent embedded with evidence-based exercise prescription knowledge. Undergraduate kinesiology students (n=15-20) evaluate the agent's recommendations across 12 structured scenarios using a validated assessment instrument measuring safety, accuracy, specificity, and professional appropriateness. Each scenario presents different populations and fitness goals, requiring students to interact with the agent and rate responses on 5-point Likert scales. Faculty experts independently assess identical AI-generated recommendations to establish inter-rater reliability. Student feedback and expert evaluations inform iterative prompt database improvements. We anticipate identifying specific gaps in AI exercise prescription capabilities, including inadequate safety screening, insufficient progression guidelines, and limited population-specific modifications. The validated prompt library will contain 25-30 evidence-based prompts organized by population and context, with effectiveness ratings above 4.0/5.0 for safety and accuracy. This research provides the first validated AI prompt library for exercise prescription, enabling kinesiology professionals to safely integrate AI technology while maintaining evidence-based practice standards. The framework can be adapted for other health professions incorporating AI into clinical practice.

Abstract Name: Spectroscopic Studies of Environmental Influences on Protein Structure and Stability

Different environmental influences are known to alter protein structure and stability. Molecules that destabilize protein structure could ultimately lead to increased protein aggregation and promote disease. In contrast, molecules that stabilize proteins can provide insight into the complexity of protein stability and opportunities for treatments to slow aggregation. This study investigates how different molecules affect the structure and stability of the model proteins, Myoglobin and α -Chymotrypsin (ACT). Spectroscopic studies of the proteins in the presence of brilliant blue, sunset yellow, glycine, histidine, and caffeine give insight into how these molecules influence protein structure and stability. The food dyes brilliant blue FCF and sunset yellow as well as glycine, histidine, and caffeine have previously been shown to influence protein structure and/or stability of other proteins. The current studies used Fourier-Transformed Infrared (FTIR) and Circular Dichroism (CD) spectroscopies to monitor how the molecules influence protein secondary structure, stability, and aggregation. CD and infrared spectra were obtained on each protein in the presence of each molecule and compared to control samples. In addition, CD spectroscopy was used to monitor how increasing temperature altered protein structures in the presence of each molecule and to determine if the molecules altered protein melting temperatures and aggregation.

Abstract Name: Bot's Effects in Public Goods Games

Do humans trust bots as much as they do other humans? This paper is a public goods experiment designed to determine whether humans cooperate with artificial intelligence in public goods games. There is a lack of research that studies human-bot interactions within public goods games. According to previous research in economic study, humans are more reluctant to cooperate with bots than with humans within the adjacent field of trust games. If this is true, participants will contribute less on average to groups with bots than groups without them. As humans interact more with AI agents, it becomes increasingly likely that these agents will participate directly in economic activity, making it much more important to study interactions between humans and bots in economic scenarios. Such a scenario that provides a particular interest is the provision of public goods, which require at least some form of cooperation to enable the successful procurement of funds. In this experiment, we examine the effects of such agents participating in 10 rounds of repeated provisioning of public goods with a ratio of 50% humans. Several control groups will be run in a similar manner. In each session, there is always a total of four participants. Depending upon if a group was part of the treatment or control, two bots would occupy two participant slots. We predict that the human participants will not cooperate with such artificial agents at the same level as they cooperate among groups with solely human participants in the provision of public goods. Our results suggest that there is not a difference in contribution between mixed human-bot groups and human-human groups.

Abstract Name: The Racial Limbo of Indigenous Identity

This project examines how and why Carolinian Tribes referred to as “Croatan” were portrayed in contradictory lights across the Federal Writers Project and Farm Security Administration photographs, as well as the modern ramifications for those portrayals. During the first half of the twentieth century, Native Americans in the Carolinas had a unique racial experience, being in a time with little distinction between Black and White. In analyzing their experience, this project will compare Native peoples’ own conceptions of their identities to outsider portrayals, based on photos taken by the Farm Security Administration and life histories recorded by the Federal Writers Project, providing a multi-angled view of the Native American racial experience. Archival photographs in the Library of Congress label individuals that we now understand to be Lumbee as “Indian Mixed-Breeds.” However, in life histories of Natives from the same area, during the same time, narrators clearly identify themselves as “Indian,” not of mixed heritage. These contradictory representations are common for communities referred to as “Croatan” in both North and South Carolina. Such discrepancies left these communities in a form of racial limbo for decades, sticking them somewhere between black and white with an unclear place in society that affects how they are viewed today. This project determines the source of these discrepancies through a comparative analysis of Native Kinship structures compared to Western ideals of lineage utilizing a lens that re-centers Native voices, adding much needed nuance in our understanding of racial history in the Carolinas. The ramifications of this project include supporting tribal sovereignty efforts, particularly for the Lumbee, returning tribal histories, healing racial trauma, and further developing the current understanding of race relations in the southeast. Furthermore, it allows Native voices to be elevated in direct contrast to the colonial ones that have historically silenced them.

Abstract Name: Evaluating the Potential for Resistance Evolution in *E. coli* Exposed to Silver Nanowires

Silver nanoparticles are potent antimicrobials against Gram-negative and Gram-positive bacteria, making them promising for healthcare use. However, *Escherichia coli* (*E. coli*) can evolve resistance to standard silver nanoparticles after repeated exposure, raising concerns about long-term efficacy. Silver nanowires, with sharp ends that may enhance membrane penetration, could provide both physical and chemical antimicrobial activity, potentially slowing resistance. This study tested whether *E. coli* could evolve resistance to silver nanowires. We hypothesized that their dual mode of action would create an evolutionary trap, preventing adaptation. Using *E. coli* K-12 MG1655, we determined the minimum inhibitory concentration (MIC) of silver nanowires as 10 mg/mL, then conducted a 21-day experimental evolution study at the sub-MIC 8 mg/mL. Cultures were serially passaged daily under this condition. Post- experiment MIC assays showed that *E. coli* evolved increased resistance. Whole-genome sequencing identified mutations in *cusS*, a histidine kinase regulating the copper-silver efflux pump. These findings suggest that even nanostructured silver can be overcome by bacterial adaptation. Future work will test additional nanoparticle shapes on high-touch surfaces. If resistance proves less likely in such contexts, silver-coated nanosurfaces may still hold promise for healthcare applications.

Abstract Name: Identification of a Cancer-Secreted Immune Regulatory Ligand

Squamous cell carcinoma (SCC) is a diverse group of cancers and amongst the most common types of cancer in the world. Head and neck squamous cell carcinoma (HNSCC), a particularly aggressive subtype, accounts for over 600,000 cases and 330,000 deaths annually. HNSCC typically has high T cell infiltration in their tumors, making these patients promising candidates for immunotherapies. Despite this, immune checkpoint blockade immunotherapies have limited success on patients, with median recurrent HNSCC survival remaining at 10-15 months. Current literature supports that tumor-initiating stem cells (tSCs) play a key role in immunotherapy resistance and relapse in patients. The specific mechanism by which tSCs drive immunotherapy resistance is currently unknown and a source of continuous research. RNA-seq on tSCs have found high levels of expression of certain immunomodulatory genes, such as CD80 and cytotoxic T lymphocyte associated protein 2a (Ctla2a), which may provide mechanistic insights into tumor immune escape. Work done in our lab has found that Ctla2a knock-out reduced tumor growth and mass in immune competent mice. Additionally, we found that secreted Ctla2a in the conditioned media of cultured HNSCCs reduced granzyme B production in Killer (CD8+) T cells. This demonstrates a possible role of Ctla2a in cancer immune regulation. Future proximity labeling experiments will reveal key candidate proteins that interact with Ctla2a, which will begin to shed light on the mechanism by which Ctla2a can drive tSC immune escape and tumor relapse. Understanding how tSCs survive immunotherapy and drive relapse can unlock new avenues for treating patients with HNSCC, minimizing resistance to immunotherapies so as to maximize patient life expectancy and quality of life.

Abstract Name: Genomic and Environmental Influences on the Nasopharyngeal Microbiome and Respiratory Allergen Sensitivity

This study is focused on providing evidence for the claim that nasal bacterial population and the environmental factors that influence it predispose individuals to respiratory allergies. This study will include two groups of twenty-five individuals recruited from two geographically distinct areas in Utah with measurably different air qualities. The individuals recruited will be people who have only respiratory allergies or control individuals who have no allergies. Blood samples and nasopharyngeal swabs will be collected in order to assess nasopharyngeal microbiome (bacterial species in the nose and throat), genetic risk factors, and allergic response. The environmental air quality will be measured in PM2.5 in the two geographical locations of differing air qualities to evaluate deviations in allergic disease and nasal microbiome. The nasal microbiome will be evaluated by amplifying genes specific for the five most prominent phyla in the nasal cavity to assess deviations in relative populations of those phyla between groups living in various air qualities with varying levels of allergic response. Total IgE antibody levels will be measured by immunofluorescence to establish the degree to which an individual is reacting to their allergens. Genetic alleles for Class II Human Leukocyte Antigens will be amplified and sequenced to identify and control for genetic risk factors.

Abstract Name: Fracture Mechanics and High-Resolution X-ray Imaging of Fused Deposition Model Based Carbon Fiber Composites

Discontinuous carbon fiber reinforced composites are attractive to manufacturers in automotive and aerospace industries due to their high specific strength, low density, corrosion resistance in harsh environments, and ease of near-net shape manufacturing. Fused deposition-based 3D printing is a routine manufacturing technique now affording the capability to print layer-by-layer complex geometries for rapid prototyping and low-cost tooling. Critical factors associated with composite material quality, including fiber orientation, fiber volume fraction, and undesirable defects such as porosity can significantly influence the mechanical performance of the 3D printed load bearing part. Furthermore, processing parameters such as orientation of fibers, in-fill densities, volume fraction, and aspect ratio affect the structural integrity of the as-built part. However, a comprehensive evaluation of fracture mechanics, structure-property relationships for chopped fiber reinforced composites is not well understood. In this study, a 3D printed chopped carbon

reinforced acrylonitrile butadiene styrene-based material system is evaluated for interlaminar and fracture toughness properties. This work aims to discuss the mechanical characterization of Fused Deposition Modeled when printed with Big Area Additive Manufacturing equipment suitable for larger load-bearing components. Mechanical testing of the parts is performed coupled with digital image correlation, a non-contact full-field strain measurement technique, using high-resolution cameras to measure local strain variations along the composite parts and identify stress concentrations on the parts subjected to mechanical loading. Additionally, high-resolution X-ray computed tomography of the composite was used to obtain qualitative information, including fiber volume fractions of the fibers and porosity. High-resolution optical microscope and laser confocal imaging are used to evaluate the surface roughness of the as-built parts. Initial results for these characterizations show promise for further development of structure-property relationships for 3D printed fiber reinforced composites.

Abstract Name: The Effect of County Law Enforcement Characteristics on Crime Rates in Georgia: Evidence Using a Panel Regression Model

While law enforcement agency structure and institutional deployment strategies have been well-documented, their direct impacts on crime outcomes have not been explored in detail. The current study seeks to address this gap, exploring the impact of county-level law enforcement characteristics on crime rates in Georgia using data from the Georgia Bureau of Investigation's Uniform Crime Reporting Program, for years 2019-2023. I employ a panel regression model to explore the impact of dual-agency enforcement, vehicle deployment, and patrol hours on crime rates over time. Results indicate that despite evidence of reverse causality for dual agency enforcement, special tactics vehicle stock in rural areas, government provision of handguns in sheriff's departments specifically, and the implementation of a one-car-one-driver rule proved significant in decreasing crime rates. This suggests that while organizational features may appear secondary to broader socioeconomic drivers of crime, they offer an avenue for local governments to make tangible progress in enhancing public safety.

Abstract Name: Digital Digs: An Analysis of Archaeogaming

My research will analyze the representation of archaeology in various video games, beginning with how, at a young age, I became fascinated with the concept of archaeology through gaming. Video games such as Tomb Raider portray simplified archaeological methods, such as digging and artifact collection; however, are these methods misinterpretations of looting or rather a gateway into educating (or even misguiding) young minds about the field of archaeology? Are there video games that accurately portray archaeological practices, and where do these depictions deviate from real-world methods? Furthermore, can archaeogaming inspire a new generation of archaeologists in the digital age we live in? Ultimately, I aim to explore how digital representations of archaeology influence the public's understanding of the field, both positively and

negatively. I will examine the overlapping themes of gaming, history, cultural heritage, and anthropology, and assess whether gaming can be an effective educational tool for future archaeologists of all ages.

Abstract Name: Relationship Between Social Media And Pressure To Change One's Body, Relating To Gender Identity

College students have proven to be the most active users on social media. With the rise of social media's influence on the pressure to modify one's appearance, past research has extensively examined this correlation among cisgender females and less extensively among cisgender males. This study examines how individuals experience the correlation between social media usage and the pressure to change one's body to fit societal ideals while also highlighting the experiences of gender-nonconforming individuals (GNIs). Through the hypothesis that exposure to body-related content on social media increases the pressure of appearance change, and that this correlation is stronger for GNIs compared to cisgender individuals, this study utilized 114 college students' completed survey responses measuring average daily social media use and perceived media pressure. Ultimately, there was no significant correlation between social media use and pressure to change one's appearance, $r(112) = .15$, $p = .11$. A multiple regression was conducted showing that gender identity did not moderate this relation $R^2 = .03$, $F(3, 110) = 1.98$, $p = .122$; no main effects or interaction variables were significant. These null results suggest social media pressure could be experienced similarly across genders. Limitations for this study include grouping a wide range of gender nonconforming identities into one single survey category and social media reports lower than the average national (3 hours vs 8 hours a day), which could potentially be because of social desirability. Future research should focus on performing longitudinal designs to capture effects that could be seen over time and not in a cross-sectional survey.

Abstract Name: Free-moving Input to Spatial Hybrid Tracked Automation for Navigation & Kinetics: Alpha Prototype

Domain Transfer Methodology is a method used to better understand animal behavior by observing how animals respond in unfamiliar environments, particularly environments to which the animal is not adapted. Previous investigators explored this capacity in Goldfish (*Carassius auratus*) trained to maneuver a wheel-driven Fish-Operated Vehicle (FOV) to navigate a terrestrial environment inside a laboratory. The current project involves the design and construction of a FOV that will improve these capabilities to accommodate the solitary territorial Siamese fighting fish (*Betta splendens*) and enhance operational platform stability and maneuverability. Digital video motion capture of the subject's movements, which has less than 40ms of

latency in the current application, is used to provide navigational input to a Raspberry Pi-based platform which computes the output trajectory for direction and speed control of the device. We further improve on the initial FOV design by using tank treads instead of axial wheels to allow for greater maneuverability over a wider variety of terrain, including outdoor settings. Further improvement is made by utilizing a sonar system instead of LIDAR for collision avoidance that reduces operational platform cost. Final refinement of this device and deployment of FishTank Mark I will allow future researchers to investigate aquatic-terrestrial navigation and explore how *B. splendens* respond and engage in spatial navigation of unfamiliar contexts.

Abstract Name: Following Collagen Deposition During Zebrafish Development Using CRISPR-Mediated Integration

Collagen IV (Col4a1) is a key extracellular matrix protein whose localization informs its role during vascular development and function. Using CRISPR/Cas9-mediated fluorescent protein tagging in zebrafish (*Danio rerio*), the Venus reporter was integrated into the Col4a1 locus via plasmid injection at the single-cell stage. Embryos were then screened at 48 hours post-fertilization using fluorescent microscopy in order to observe the expression of Col4a1-Venus fusion. Col4a1-Venus deposition was observed around muscle cells and blood vessels during early development, highlighting the Col4a1 gene's contribution to extracellular matrix organization. Current efforts focus on isolating a stable transgenic line to track Col4a1 dynamics during cardiovascular development and regeneration. This approach establishes a platform for visualizing Col4a1 in vivo and advancing scientific understanding of its role in development and regeneration.

Abstract Name: Source and Solution to Suburban Sprawl: An Analysis of Potential Alternatives to Suburban Style Development

Over the past one hundred and fifty years cities across America have shifted their development focus from a traditional pedestrian centric model to a car dependent suburban model. The far reaching consequences are poor economic returns for municipal development, reduced quality of life, and negative effects on our environment. Despite these far reaching consequences, few cities are addressing the root cause of these issues and most instead focus on cheaper short term solutions (Farrell, 2002; Fischel, 2004; Stewart, 2016; Norman et al, 2006; Bird et al, 2018; Marohn, 2020; Marohn 2025). This paper aims to address these issues on the local level, using the city of Frederick, MD as a template for other cities to follow. To show some of the consequences of ignoring these issues, the cities of Salisbury, MD and Houston, TX will be used as examples of what happens when these systemic issues are ignored. To provide guidance for the template, the city of Nanaimo, BC will be used as an example of a city successfully instituting many of the recommendations of

this paper (City of Nanaimo, 2022; Traffic Calming Tools, 2025; Wurster, 2025b; Wurster, 2025c; Wurster, 2025d). Findings from this study suggest that changes can be implemented in the short and long term across cities. First, there is a need to replace harmful regulations such as minimum parking requirements, restrictive zoning requirements, and poor road hierarchies. Second, infrastructure changes like walkable districts in city centers, micro-mobility as well as public transit infrastructure between these districts, and traffic calming on local roads reduce dependency on cars (City of Nanaimo, 2022; Traffic calming tools, 2025; Williams, 2023).

Abstract Name: The Cost of a Lost Haven: When Policy Undermines Public Health Efforts and Its Implications for Black Maternal Health Outcomes in the United States

The alarming rise in maternal mortality rates among African American women since the 1990s highlights a critical public health issue in the U.S. Black women, are four times more likely to die during childbirth compared to their counterparts revealing a profound racial disparity. This inequality is rooted in interconnected systemic issues: institutional racism, geographical disparities in healthcare access, and medical biases. The Supreme Court's decision to overturn Roe v. Wade, endangers vulnerable populations through restricting access to essential reproductive health services. Protecting these services is vital for ensuring maternal well-being and reducing the current disproportionate health burden. This project uses a comprehensive analysis of scholarly data and existing literature to examine how recent policy changes are likely to exacerbate maternal health outcomes for a population riddled with socioeconomic and health inequities. The Journal of Racial and Ethnic Health Disparities states that low-income Black women are projected to be the most negatively impacted following the Supreme Court's decision. This is due to high rates of unmet needs for contraception, unintended pregnancies, poverty, and barriers to legal abortion access. Historical evidence indicates that the legalization of abortion in 1973, has previously enhanced educational and employment opportunities for Black women. In stark contrast, the current policy landscape jeopardizes these gains, particularly for low-income individuals facing barriers to comprehensive reproductive healthcare. The audience will gain insight into the relationship between public policy and health outcomes, particularly the ways systemic oppression intensifies maternal mortality rates among minority women. Discussion will surround the repercussions of restricted reproductive access, the pervasive impact of medical mistrust, and the overarching need for policies that prioritize public health. Ultimately, this presentation will underscore the urgent need to reevaluate public policy initiatives to ensure they align with the needs of vulnerable populations and advocate for structural changes that promote equity in maternal healthcare.

Abstract Name: Magnesium-Enhanced Methane: A New Metalized Fuel Concept for Mars Return Missions and Next-Generation Propulsion Systems

Liquid methane stands out as an option for in-situ resource utilization (ISRU) on Mars although its relatively substantial activation energy required for bond breaking restricts its effectiveness as a propellant for return missions. Recent experimental studies indicate that metal nanoparticles could improve methane's reactivity.

The fundamental surface-reaction mechanisms are not well comprehended. This research explores whether magnesium, a light metal plentiful, in soil can reduce methane's dissociation energy barrier via catalytic surface interactions. By employing density theory (DFT) alongside a Mg(0001) 3×3×4 slab configuration I determined adsorption energies, refined reaction geometries and traced the $\text{CH}_4 \rightarrow \text{CH}_3 + \text{H}$ dissociation route through a nudged elastic band (NEB) method. Methane exhibits adsorption, on Mg(0001) with an energy of -0.18 eV, indicative of physisorption yet surface-driven polarization notably reduces the strength of the specific C–H bond. The NEB calculations show an activation energy barrier of 0.52 significantly less than the dissociation energies in the gas phase demonstrating that magnesium surfaces can effectively facilitate the initial stage of methane combustion. This discovery is crucial, for propulsion: a lowered activation barrier implies that dispersing Mg nanoparticles within methane may speed up ignition reactions and enhance the total energy output. To link atom-scale findings with engine-scale outcomes the subsequent stage of this study incorporates the DFT-calculated barrier into a reacting-flow fluid dynamics (CFD) simulation to assess combustion rates and thermal characteristics in a metalized methane fuel blend. Ultimately this investigation offers a physics-grounded basis, for an ISRU-compatible propellant concept where methane generated on Mars is improved with magnesium extracted from local regolith. Such a system could enable more efficient Mars-to-Earth return missions by improving the reactivity of methane without requiring imported oxidizers or catalysts. This study demonstrates how fundamental surface-reaction modeling can guide the design of next-generation space propulsion technologies.

Abstract Name: Demonstrating ComEA Protein Assists DNA Uptake in *Pseudomonas stutzeri*

Natural transformation, the ability to uptake foreign DNA, is a mechanism possessed by many bacterium species, providing biotechnological advancements in research and aiding in the species' evolution, though natural transformation is only present within a small group of subspecies in the *Pseudomonas* genus. One mechanism of DNA uptake utilizes a gene called *comEA*, translating protein ComEA which binds and guides exogenous DNA into the periplasm. Although numerous species of bacteria are known to utilize the *comEA* gene, it is currently unknown if *Pseudomonas stutzeri* requires this gene to accomplish natural transformation. Our study utilizes standard DNA editing techniques to delete the *comEA* gene from *P. stutzeri* and determine if it is capable of DNA uptake in the absence of the gene. However, we hypothesize that *P. stutzeri* will not be able to uptake DNA with the *comEA* gene deletion. We will then knock in the gene to confirm that the ComEA protein is truly necessary for *P. stutzeri* to undergo natural transformation. This study addresses an existing gap in knowledge by confirming the natural competence protein mechanism in *P. stutzeri*. Investigating how *P. stutzeri*, a soil-dwelling bacterium found across the globe, incorporates new DNA into its genome points to its robust evolution and survivability.

Abstract Name: Neurovascular Architecture in a Tuberous Sclerosis Complex Model

Tuberous Sclerosis Complex (TSC) is a neurodevelopmental disorder caused by inactivating mutations in the TSC1 or TSC2 tumor suppressor genes. TSC1 and TSC2 encode a protein complex that serves as an upstream negative regulator mTORC1. In its absence, the upregulated expression of mTORC1 facilitates development of lesions throughout multiple organ systems. Within the brain, growths appear in the form of Subependymal Giant Cell Astrocytomas (SEGAs), Subependymal Nodules (SENs), and cortical tubers. Cortical tubers and affected cells are believed to promote hyperexcitability of their respective networks, reflecting a pro-epileptogenic shift in the brain. As a result, seizure generation remains one of the hallmark phenotypes of TSC. Recent studies in full knockout mouse models have shown that seizures generate compensatory changes in more than just neural networks. Often accompanied with increased angiogenic activity, TSC-induced epilepsy has been linked to vascular abnormalities. However, it remains unclear if TSC2 affects neurovasculature in the absence of epilepsy. To address this question, a transgenic mouse model was employed to examine the impact of haplosufficiency on vascular characteristics. Germline heterozygous and wild-type mice were cryosectioned and subject to immunohistochemical staining (IHC) to compare vascular structure. Confocal z-stack imaging revealed no differences in the overall structure and density of veins within the prefrontal cortex. These findings suggest that a single copy of the TSC2 allele provides enough regulation of mTORC1 to prevent the angiogenic changes present in full knockout models.

Abstract Name: Communication Tool Preferences in Global Virtual Teams: Beyond Conflict Management
“The single biggest problem in communication is the illusion that it has taken place.” — George Bernard Shaw

This research investigates how multilingual identity influences communication tool preferences and self-efficacy in global virtual teams, examining the mediating role of conflicts. Drawing on Media Richness Theory, Social Identity Theory, and Conflict Management Theory, we hypothesized that (H1) individuals speaking more languages prefer richer communication tools (video calls) over leaner channels (email); (H2) richer tool preferences reduce both task and relationship conflict; (H3) task conflict is positively related to self-efficacy while relationship conflict is negatively related to self-efficacy; and (H4) tool selection and conflicts sequentially mediate outcomes. Analyzing data from 2,823 students across 629 teams in the 2022 Spring X-Culture project using SPSS PROCESS, we examined ten communication scenarios. Our findings challenge the hypothesized conflict-centered framework: the direct way (multilingual identity → tool preferences → self-efficacy) proved significantly stronger than the conflict-mediated pathway. In "introduction" and "member missing" scenarios, multilingual identity increased preference for high-richness tools, enhancing self-efficacy directly, with conflict playing minor mediating roles. The relationship between multilingual identity and tool preferences proved context-dependent: significant positive correlations in three scenarios, non-significant correlations in five routine scenarios, and slight negative correlations in two explanatory contexts. While information-rich tool preferences consistently correlated negatively with both conflict types (especially relationship conflict), these reductions played surprisingly modest mediating roles. Both conflict types negatively impacted self-efficacy (especially task conflict), contradicting H3. This reversal occurs because virtual environments lack the non-verbal cues that help teams navigate disagreements productively. The critical exception emerged when addressing the "member missing" question: language member significantly predicted tool preferences ($\beta=0.0530$, $p<0.001$), which reduced both conflict types, and task conflict powerfully mediated self-efficacy ($\beta=-2.6564$, $p<0.001$). These findings reveal that conflict mechanisms activate specifically during communication crises, while normally, tool preferences

enhance capability through direct pathways—reduced cognitive load, enhanced coordination, and psychological safety—rather than primarily through conflict reduction.

Abstract Name: Gas and the Gut: Cattle Rumen Microbiomes and Methane Emissions

Cattle that eat the same feed and come from the same environment can emit methane (CH₄), a potent greenhouse gas, at vastly different levels. An estimated 32% of anthropogenic CH₄ can be traced to ‘enteric fermentation’ in livestock production. During enteric fermentation, specialized microorganisms will digest complex plant fiber to create compounds like acetate and hydrogen (H₂). Some of these organisms, called methanogens, will consume and use these products to produce CH₄. Emerging data suggests natural inter-animal variation in CH₄ emissions could derive from host genetics or differences in rumen microbial digestion. Here, we analyze 16S rRNA gene amplicon sequencing from the rumen of twenty beef cattle of varying CH₄ emission levels to look for differences in the structure and composition of their microbial communities. There was no significant difference in microbial community diversity by host CH₄ emission level. Association tests at the genus and ASV levels revealed relationships between low residual CH₄ emissions and the genera *Megasphaera*, *Prevotellaceae*, *Ruminococcus*, and *Gastranaerophilales*. Network analysis of the high and low CH₄ communities revealed disrupted relationships between methanogens and other members of the community. The methanogens *Methanobrevibacter* and *Candidatus Methanomethylophilus* were significantly associated with *Gastranaerophilales* and *Prevotellaceae*, respectively in the low CH₄ network. These interactions were absent in the high CH₄ network. This suggests that the interactions of the low CH₄-associated microbiome members and methanogens contributes to the reduced CH₄ emissions. The findings of our work begin to explain why some cattle emit higher methane levels compared to others, and may aid in finding solutions to reduce methane emissions in cattle while keeping their feeding efficiency and meat production high.

Abstract Name: Bridging the Gap In Quantum Education from Beginner to Advanced Resources

The rapid expansion of the quantum technology sector has intensified the need for a well-prepared workforce capable of engaging with quantum concepts at multiple levels of expertise. Yet, despite a growing number of introductory outreach activities and freely available advanced university materials, a substantial educational gap persists between beginner-friendly explanations and mathematically rigorous quantum computing resources. This project addresses that gap by developing an accessible, structured, self-paced online course designed for learners—particularly high school students, early undergraduates, and teachers—who lack the mathematical background typically assumed in quantum education. Building on findings from the 2025 Science Math Resource Center (SMRC) Quantum Summer Academy and informed by direct student

feedback, the project translates complex quantum ideas into scaffolded lessons that gradually build conceptual fluency. Using a custom website built with Java, React, and HTML, the course introduces classical computing foundations, core quantum principles, qubits and hardware, quantum gates, and simplified algorithms, paired with interactive simulations and introductory Python exercises. Pilot testing with college and high school participants will guide iterative refinement of content clarity, usability, and pedagogical effectiveness. By creating an approachable yet rigorous pathway into quantum computing, this work aims to reduce barriers to entry, strengthen Montana's developing quantum workforce pipeline, and contribute scalable educational models for national quantum outreach initiatives.

Abstract Name: Bioinformatic Characterization of Mutations Associated with Enhanced Acetate Metabolism in *Escherichia coli*

The conversion of non-food lignocellulosic biomass, such as from trees or grasses, into sugars that can be converted into ethanol by fermentation is key to the future U.S. energy infrastructure. The accumulation of acetate during lignocellulosic biomass pretreatment inhibits microbial fermentation and limits bioethanol yields. This study aimed to characterize *Escherichia coli* strains engineered to efficiently utilize acetate as a sole carbon source to support acetate detoxification prior to yeast fermentation. Eight mutant strains were generated using either spontaneous or ethyl methanesulfonate (EMS) mutagenesis, then characterized using whole-genome sequencing and comparative bioinformatic analysis. Variant detection was performed using two pipelines, Bowtie2 + bcftools and Bowtie2 + DeepVariant, to evaluate differences in sensitivity and precision. The mutants exhibited enhanced growth on acetate despite lacking mutations in acetate metabolism genes (*acs*, *pta*, *ackA*). Instead, changes occurred in genes associated with replication and potentially global regulation of gene expression (*dnaA*), acid resistance (*gadX*), glycogen metabolism (*glgX*), membrane stability (*ytcA*), and proton export (*ECOLC_RS20895*). These mutations collectively improved stress tolerance, pH homeostasis, and metabolic efficiency. The results suggest that global physiological remodeling, rather than direct enzymatic modification, underlies enhanced acetate assimilation in *E. coli*, providing a genetic foundation for designing robust microbial strains for bioethanol production.

Abstract Name: ROBO1 Targeting and Payload Selection Reveal a Preclinical Framework for Antibody–Drug Conjugates in Pancreatic Cancer

Pancreatic cancer has a high mortality, with a 5-year survival rate of 13%. Each year, more than 67,000 new pancreatic adenocarcinoma (PDAC) cases are diagnosed. Systemic chemotherapy provides only a modest survival benefit and is often accompanied by significant toxicity. With limited treatment options and poor prognosis, antibody-drug conjugates (ADCs) have emerged as a promising modality for targeted cancer therapy. This study aims to identify PDAC-enriched cell-surface proteins and potential payloads to develop an ADC. Expression profiling of Mia PaCa-2 and PANC-1 cell lines, as well as PDAC patient-derived

xenografts (PDXs) was done along with proteomic analysis of patient tumor models. Based on these analyses, 19 membrane proteins were identified as viable targets, of which ROBO1, CD109, and PIK3C3 were selected for further evaluation. Internalization assays of PDXs showed ROBO1 having the most favorable internalization kinetics. Immunofluorescence staining of six PDAC PDX models confirmed strong, predominantly plasma-membrane ROBO1 localization, supporting its suitability as an ADC target. To find a suitable payload, Mia PaCa-2, PANC-1, and multiple PDX lines were exposed to commonly used classes of ADC payloads, narrowing the field to a subset of microtubule- and DNA-targeting agents. Specifically, duocarmycin and PNU-159682 were identified as the best payloads for an ADC. Collectively, these findings nominate ROBO1 as a compelling PDAC ADC target and duocarmycin and PNU-159682 as compelling PDAC ADC payloads with intrinsic efficacy in PDAC, providing a preclinical foundation for the development of a ROBO1-directed ADC for pancreatic cancer.

Abstract Name: METHODS OF ENGAGING MALE ADOLESCENTS WITH AUTISM

Current methods used by teachers and school administrators in order to interact with male adolescents ages 14-18 with level 1 autism spectrum disorder (ASD) in educational environments, such as the use of antipsychotics to treat aggression and directly addressing negative behaviors, cannot be generalized to all male adolescents ages 14-18 with level 1 ASD. This is because of the variance in ASD adolescents' reactions and responses to social interactions and cues. Anxiety in male adolescents ages 14-18 with level 1 ASD is a common cause for negative behaviors, such as aggression and verbal disruption, which may hinder cognitive development appropriate for an adolescent in high school. Without sufficient cognitive development, male adolescents ages 14-18 with level 1 ASD may struggle with verbal communication and interactions in higher levels of education and professional careers. This comprehensive literature review explores how treatments such as cognitive behavioral therapy and mindfulness-based therapy have shown significant impacts on decreasing negative behavioral patterns and increasing social participation for male adolescents ages 14-18 with level 1 ASD. These may be feasible options for teachers and school administrators to use to effectively engage with male adolescents ages 14-18 with level 1 ASD. By implementing these therapies into educational settings, educators can better communicate with the adolescents, ultimately fostering the cognitive skills of male adolescents ages 14-18 with level 1 ASD as the adolescents enter higher levels of education and begin professional careers.

Abstract Name: Primary Care Access and the Social Determinants of Health in Richmond, Virginia: A Neighborhood-Level Assessment

Access to continuous and comprehensive primary care is essential for improving health outcomes and meeting individual and community needs, yet structural inequities and social determinants of health (SDOH) limit access in marginalized communities. At a state level, Richmond ranks highly in terms of primary care

provider (PCP) supply, but low in primary care utilization, patient outcomes, and expenditures. This suggests local disparities in provider distribution and access to care. While this issue is shown at a city level, no research has examined this issue at a neighborhood scale. This research investigated how SDOH characteristics are associated with primary care availability in low-income neighborhoods across Richmond. A secondary descriptive data analysis was conducted at national, state, and city levels to identify gaps in provider distribution and barriers to care. Community access mapping was conducted in Richmond's under-resourced communities to ascertain primary care access and SDOH. Researchers individually scored each neighborhood's SDOH data and healthcare indicators, followed by consensus coding to create indicator ratios. Analysis revealed that neighborhoods with higher poverty, food deserts, low educational attainment, and shorter life expectancy had less access to primary care and healthcare facilities. Public housing communities had consistently low SDOH scores and inadequate primary care services, suggesting that systemic inequities correlate with access to care. Only 12 PCPs were identified for an estimated 64,222 residents in the East End and Northside. Housing instability, socioeconomic status, and food access were the strongest predictors of gaps in primary care availability. These findings imply that improving primary care access in under-resourced communities requires addressing underlying social and structural inequities, not just expanding clinical services. Future work will include IRB-approved community focus groups with public housing residents, free clinic patients, and health leaders, expanded community access mapping across Richmond, and an executive summary to inform citywide primary care planning.

Abstract Name: Perceptions of AI in Mental Health and Therapy: A Cross-Sectional Study

Artificial Intelligence (AI) is becoming increasingly integrated into the workforce, raising important questions about how the public will respond to its implementation in sensitive fields, especially as many industries report rapid growth in the use of automated and AI-assisted tasks. As discussions about the adoption of AI continue to expand, mental health care represents one of the clearest examples of a setting where public reaction may significantly influence implementation, given its reliance on interpersonal connection and trust. The attitudes and perceptions of service users are crucial, especially as relational dynamics and user comfort are particularly fundamental for successful outcomes and patient care. Despite the rapid rise of AI-mediated emotional support and companionship, limited research has examined how young adults, the demographic most likely to seek counseling, perceive the use of AI in these settings and in relation to sensitive emotional or interpersonal concerns. Therefore, the purpose of this study is to explore and characterize the perceptions of 18-24-year-old university students in the Mid-Atlantic United States toward AI-based mental health support and therapy. Using a two-part online survey instrument, this study aims to determine how young adults evaluate AI on core non-clinical therapist characteristics such as empathy, trust and confidentiality, communication, working alliance, self-disclosure, confidence, and openness, and which types of responses (AI-generated or human-generated) participants perceive as most supportive when presented with scenario-based prompts involving negative emotional experiences. The insights gained from this research may help identify factors that influence the acceptance of artificial intelligence in therapeutic contexts and guide the development of tools that better align with user expectations. These findings may also support future research on optimizing AI communication strategies, understanding how user characteristics shape responses to AI-based support, and determining where AI can appropriately supplement or enhance traditional mental health services.

Abstract Name: The Influence of Cultural Distance, Technological Readiness, and Reciprocal Investment Patterns on U.S. Bilateral FDI Flows.

This study explores how the interaction between cultural distance, technological readiness, and reciprocal investment patterns influences bilateral Foreign Direct Investment (FDI) flows between the United States and its partner countries. To conduct this study, we utilize an extensive dataset of 83 countries compiled from various World Bank sources, Hofstede's cultural indices, and other measures of technological readiness to create a bilateral investment framework to analyze both U.S. outbound and inbound foreign direct investment. We employ fixed effects regression analyses to evaluate the multidimensional impacts of culture, technology, and economic ties on investment behavior. The results show that technological readiness is strongly associated with higher levels of bilateral FDI flows. Additionally, the findings reveal an important moderating effect: cultural distance makes the positive influence of technological readiness weaker on FDI flows, indicating that cultural compatibility is essential for countries to fully leverage technological advantages in international investment. The results of this research indicate that countries wishing to invest more heavily in each other's markets do so by first establishing a strong technological base, then building strong cultural relationships.

Abstract Name: The Genomics Education Partnership (GEP) — Supporting Course-based Undergraduate Research Experiences in Genomics Across Higher Education Institutions Nationwide

The Genomics Education Partnership (GEP) is a nationwide Community of Practice with 260 faculty from 209 institutions that aims to provide authentic research experiences in genomics and bioinformatics to undergraduate students in the classroom. In 2024–2025, >1,500 students participated in courses that utilize GEP materials. Under a distributed leadership model, GEP faculty develop and update curriculum materials, host training workshops, and develop assessment instruments to enable the implementation of Course-based Undergraduate Research Experiences (CUREs). Through mentorship and professional development programming, faculty support each other in implementing CUREs. Current GEP research projects investigate genes involved in specific pathways in *Drosophila* (e.g., insulin signaling, oxidative stress, sexual development), venom production in parasitoid wasps, and eggshell formation in the critically endangered Puerto Rican Parrot. The GEP has developed a web-based platform (thegep.org) which hosts curriculum materials and custom bioinformatics tools that enable students to participate in these research projects. Students learn to use multiple bioinformatics tools (e.g., BLAST, UCSC Genome Browser), and integrate multiple sources of experimental (e.g., RNA-Seq data) and computational evidence (e.g., sequence

alignments, gene predictions) to construct gene models. GEP Virtual TAs provide additional real-time support to students. For quality control, reconcilers reconcile two independent annotations of each gene. Finalized gene models with students as lead authors (e.g., microPublications), and larger studies using student research from multiple annotations have been published. Regional Node Meetings provide students professional development opportunities to present their work, and to interact with GEP faculty, and other scientists and student researchers. The GEP is currently supported by NIH IPERT-R25GM160660 to Laura K. Reed (LKR) and has started a 501(c)(3) nonprofit wing. The data presented here was generated in part with support from NIH IPERT-R25GM130517 and NSF IUSE-1915544 to LKR.

Abstract Name: Alan Chan and the Commodification of Nostalgia in Post-Handover Hong Kong

This paper examines the influence of Hong Kong designer Alan Chan on the city's design identity through a critical lens. While widely celebrated for blending Eastern heritage with Western modernism, Chan's work reveals a complex relationship between cultural authenticity and commercial globalization. Drawing from the historical background before the beginning of Alan Chan's career, we can see the origin of design in Hong Kong as a whole. Through a small biography, analyzing his technique of drawing from nostalgia, and collecting inspiration from Eastern manufactured markets made for the Western consumer, we can see the problematic ways his work presents Hong Kong in the international spotlight. This paper argues that Chan's use of nostalgia and "Chineseness" transforms cultural heritage into a marketable aesthetic, reflecting Hong Kong's postcolonial tension between identity and global branding.

Abstract Name: Deep Learning-Based Cheese Classification

With the rapid development of artificial intelligence and computer vision, image-based recognition has become a promising research direction with applications in agriculture and industrial manufacturing. To reduce development costs, pre-trained deep learning models can be leveraged through transfer learning. This project investigates whether deep learning can reliably classify types of cheese, aiming to support the cheese industry through automated recognition. A publicly available dataset from Kaggle, All The Cheese, was utilized. However, the original dataset contained mislabeled, duplicate, and low-quality images. To address this, we developed a multi-stage cleaning pipeline leveraging the PIL library, the CleanVision toolkit, and the Gemini semantic filter. The resulting dataset consisted of 1,733 high-quality samples across six categories: Bloomy, Blue, Fresh, Hard, Semi-Soft, and Washed-Rind. The data were then split into 80% for training and 20% for validation, with data augmentation applied to increase diversity. Five models, ConvNeXt-Tiny, ResNet-18, DenseNet-121, EfficientNet-B0, and Vision Transformer (ViT), were implemented in PyTorch. All models were initialized with ImageNet pretrained weights and fine-tuned on the cleaned dataset. Evaluation metrics included accuracy, precision, recall, and F1-score. Among the models, EfficientNet-B0

achieved the highest validation accuracy of 90.85%, outperforming the others while maintaining a compact architecture with only 5.3 million parameters. DenseNet-121 showed balanced performance, while ViT underperformed, likely due to the relatively small dataset size. Confusion matrix analysis revealed that most misclassifications occurred between washed-rind and semi-soft cheeses due to visual similarity. These results demonstrate that convolutional neural networks achieve stable, efficient performance in fine-grained food image classification. This research demonstrates the feasibility of deep learning for automated cheese recognition and provides a scalable framework for future food-image classification research.

Abstract Name: Alexphander's Gene 50 is a Molecular Determinant of Prophage Mediated Protection

Mycobacteriophages, also known as phages, are a group of viruses that exploit bacterial hosts as a means of reproduction by infection. These methods of infection that phages utilize are lytic and lysogenic infection. Lytic infection is the process in which a phage binds to the surface of a host cell to release its genomic DNA to encode necessary genes to assemble phage particles, which lyses the cell. Lysogenic growth is a different process in which a phage infects a bacterial cell and integrates its genomic DNA into the DNA of the host. We have found that Alexphander can successfully form a stable lysogen, which is immune to secondary infection from itself, as well as Schoolbus and LilPharaoh. Alexphander encodes an immunity repressor, gene 50, that we hypothesize is sufficient in protecting the Alexphander lysogen by binding to DNA and suppressing lytic genes of an infecting phage. Due to the unrelatedness of phages Schoolbus and Lil Pharaoh to Alexphander, we also hypothesize that gene 50 will be insufficient in protection during the formation of the Alexphander lysogen. In this study, we aimed to provide evidence about gene 50's role as an immunity repressor and the sole mediator of homotypic protection. In previous studies, we have found that when gene 50 is overexpressed by the exogenous plasmid, it is cytotoxic, resulting in cell death. In this study, I describe the assembly of the integrative plasmid that expresses gene 50 at native levels in order to repress overexpression to mitigate cytotoxicity. We have found that when gene 50 is expressed at native levels, Alexphander and Schoolbus are unable to infect, while Lil Pharaoh is sufficient. This reveals that gene 50 is the sole mediator of homotypic immunity and that there is an additional mechanism that promotes heterotypic protection.

Abstract Name: IL-33-Mediated Mast Cell Function is Female-Dominant

Asthma affects over 300 million people worldwide, and its severity has continued to increase, especially in women. It is partly driven by IL-33 released from damaged bronchial epithelial cells, which triggers airway inflammation. Although mast cells are known to play a key role in IL-33-mediated responses, it is unclear whether mast cell activation differs between males and females. Therefore, we investigated sex-based

differences in mast cell responses to IL-33, hypothesizing that IL-33-mediated mast cell responses are female-dominant. Using ELISAs, we found that IL-33-induced production of inflammatory cytokines was significantly higher in female bone marrow-derived mast cells (BMMCs) than in those derived from males. We also found that female mast cells secreted greater amounts of inflammatory lipid mediators than males, including LTE4, TXB2, and PGD2. We then studied IL-33-induced cell signaling. This revealed greater IL-33-mediated activation of the kinase JNK in females than in males. In contrast, the related kinases ERK and p38 were more activated in male mast cells. Surprisingly, activation of the transcription factor NFκB, which is critical for IL-33 signaling, displayed no differences between males and females. We found sexual dimorphism in the IL-33 response among mast cells from several strains of mice, including C57BL/6J, C3HeJ, and BALB/cJ. Additionally, these data were consistent when studying peritoneal mast cells that differentiated in vivo. Collectively, the data support the hypothesis that IL-33-mediated mast cell function is female-dominant and linked to cell signaling differences. Given the important role mast cells play in allergic disease, our results suggest fundamental differences in male and female allergic inflammation that may be targeted clinically.

Abstract Name: Knowledge Triple Filtration for Explainable Question-Answering

A significant application of Natural Language Processing (NLP) is the development of question answering (QA) systems, which are instrumental in enabling information retrieval from extensive knowledge bases. This research explores Graph Retrieval-Augmented Generation (GraphRAG) and PathRAG, techniques that enhance data retrieval and processing capabilities in NLP. GraphRAG leverages graph structures to improve data connectivity, while PathRAG optimizes retrieval paths, both aiming to improve the accuracy, transparency, and reliability of Medical QA systems. In a typical QA system, users find it difficult to trace answers back to the source. However, our system can enhance answer traceability, allowing users to query vast collections of medical studies and receive verifiable, evidence-based answers, thereby supporting healthcare professionals to make better-informed decisions and helping patients gain more reliable insights into their health. To address the challenge of balancing retrieval quality with explainability, we developed a novel GraphRAG system. This system employs a graph filtration strategy using the Linking Term Count metrics to reduce noise and redundancy before query-time retrieval. From our preliminary tests, we expect our system to enhance efficiency and explainability compared to traditional RAG systems. To evaluate performance, we measure the accuracy, and efficiency is assessed by comparing the retrieval time between GraphRAG and RAG systems. Our work improves the traceability and accuracy of medical QA systems, this research contributes to developing AI tools that make medical knowledge more transparent, verifiable, and accessible to both healthcare professionals and patients.

Abstract Name: Ableism Analyzed

Ableism is prejudice and discrimination against the disabled community. Ableism is frequently left out of discussions about civil rights, human rights, dignity, and social justice, despite the fact that ableism impacts not only the largest minority in the world, but everyone in the world. This project is an analysis of ableism. I began my research in 2022 and have continued for the past three years in the hope of answering this question: How is ableism defined and perpetuated? In other words, what is ableism, how does it manifest itself, and why does it exist? For my research, I read various articles, studies, and historical documents from sources such as the AMA Journal of Ethics, the United States Holocaust Memorial Museum, the World Health Organization, and the American Psychological Association. I included articles from peer-reviewed academic journals as well as articles written by other disabled people. My essay is an explanation of my findings about the impact of ableism and its historical and cultural roots. I also describe and analyze the ableist beliefs, attitudes, and behaviors that are prevalent today, particularly those in scientific and religious communities. Ableism is entrenched in society, the medical field, and theology. It is crucial that people understand ableism and its implications to begin fighting against the harm it causes.

Abstract Name: Femicide Discourse in the 2024 Mexican Presidential Campaign

Despite widespread public concern regarding gender-based violence and rising femicide rates in Mexico, political responses to such issues vary considerably across candidates and parties. This project will examine how the top three candidates in the 2024 Mexican presidential election framed, discussed, and proposed policy plans for femicides in their campaign rhetoric. While separate scholarship on Mexico's election campaigns and femicides exists, the two fields rarely intersect, with little research on how the topic of femicide appears in electoral discourse. Additionally, most research offers explanations for femicide occurrences, such as patriarchal social structures, victim-blaming media narratives, and machismo social discourse, but fails to analyze how politicians and campaign decisions shape public narratives and influence policymaking. The project will rely on campaign speeches, debate transcripts, and social media posts from Claudia Sheinbaum, Xóchitl Gálvez, and Jorge Álvarez Máynez during the 2024 election cycle. I will code each for frequency of mention, rhetorical framing, and any references to combative policy proposals to understand how each candidate constructs narratives around responsibility, urgency, and the need for institutional solutions. The results will likely find that candidates use femicides as a political tool to attract voters, rather than propose actual solutions. By analyzing how candidates discuss femicides, the project aims to help voters better recognize the strategies politicians use, enabling more informed electoral choices and demanding greater accountability for candidates' claims.

Abstract Name: Economic Development and Air Service Impact: A Global and Regional Perspective

Airlines and commercial air service have connected our world for decades, bringing people from across the globe together, driving international trade, travel, and business development. Readily available air service helps drive business investment and economic growth, which are vital to enhancing a community's GDP. Economic development and external investment are crucial to stimulating growth in any area, especially in rural areas with limited connectivity and access to capital. Feeder air service and programs like the Essential Air Service (EAS) help bring in connectivity and prosperity to these underserved rural areas and regions. In this study, Class D Airports in Alabama, Georgia, Tennessee, and Kentucky with commercial air service will be researched to find the economic impact of the air service. Class D airports are categorized as those with an active air traffic control tower, and pilots must establish two-way radio communication within the Class D airspace. Specifically, the GDPs of communities with Class D airports that have commercial air service will be compared with those without commercial air service. Quantitative GDP data collected from the U.S. Bureau of Economic Analysis will serve as the primary research method. To complement the primary process, qualitative data collected from interviews with airport managers within the sample will serve as the secondary research method. The primary objective is to assess the role that regional air service plays in driving economic development in these communities.

Abstract Name: Environmental Drivers of Telomere Length Variation in Migratory Songbirds

Telomeres, non-coding DNA sequences located at the ends of chromosomes, are essential for protecting genetic material and are closely associated with key cellular processes such as senescence. In birds and other taxa, relative telomere length (RTL) is positively associated with an individual's physiological condition and lifespan. Evidence suggests that oxidative stress can accelerate telomere degradation, including environmental stressors such as high temperatures, UV radiation, and variable weather. Shorter telomeres, particularly during an organism's early developmental stages, are associated with reduced lifespan and fecundity. Increasing evidence suggests that telomere degradation, combined with environmental stress, contributes to declines in wildlife populations. Understanding how environmental change affects organismal physiology and the extent to which these effects scale up to adaptive behaviors remains a key knowledge gap. We examined variation in RTL among nestlings of two migratory bird species, the Common Yellowthroat and Dickcissel, to evaluate how early-life environmental conditions influence physiological condition. We tested whether RTL differed between these species in relation to various environmental and ecological conditions during their developmental period (e.g., UV radiation exposure, temperature, precipitation, nest microhabitat). Telomere length was quantified using quantitative PCR, comparing the ratio of telomeric repeat sequences to an amplified single-copy reference gene (GAPDH). We hypothesize that nestlings raised in nests with greater environmental exposure will exhibit shorter RTL, reflecting elevated physiological stress. Additionally, we predict seasonal patterns in telomere dynamics, with nestlings developing later in the breeding period showing reduced RTL. By analyzing species-specific patterns in telomere dynamics, this study provides insight into how microhabitat structure and environmental conditions influence the early-life physiological state of migratory songbirds.

Abstract Name: Development of a Polytetrafluoroethylene (PTFE) Pelletizer and Extruder with Optimized Processing Conditions to Improve Expanded PTFE Graft Performance

Expanded polytetrafluoroethylene (ePTFE) grafts are commonly used in vascular bypass surgeries and peripheral arterial reconstructions to repair and reconstruct blood vessels. However, current ePTFE grafts often cause scar tissue formation due to their dense structure, contributing to compliance mismatch and limiting their long-term effectiveness and integration with the host. The goal of this research project was to utilize multiple characterization techniques to determine the melting point, crystallinity, and microstructure of raw PTFE resin, heat-treated resin, and extruded and expanded PTFE tubing. Characterization techniques included the determination of the melting point using Differential Scanning Calorimetry (DSC), analysis of the surface morphology using scanning electron microscopy (SEM) images, and calculation of crystallinity percentages from Raman spectroscopy data. A PTFE pelletizer was designed to be compatible with a mechanical tensile tester and optimized to remove air and compress the PTFE resin and lubricant mixture to create a condensed pellet prior to extrusion. This will allow for student-led ePTFE production to reduce overall costs and the tunability of tubing production factors to optimize tubing thickness, mechanical properties, and compliance. These techniques aim to guide the fabrication of ePTFE grafts created by student researchers to enhance biological integration with vasculature and long-term clinical performance.

Abstract Name: Visualization of ancient humans from the Allen Ancient DNA Resource using ArcGIS: applications of interactive web maps for ancient DNA studies

The Allen Ancient DNA Resource (AADR) is a widely used resource that collects ancient DNA from humans across the globe. With over 10,000 published ancient humans included to date, the AADR has greatly facilitated the study of human population history and adaptation. However, one barrier to effectively utilizing this resource is the lack of a graphic user interface to assess the availability of ancient human samples for a region or time period of interest. Here, we developed a web-based interactive map to visualize ancient humans from the AADR. With this freely available, public-facing, constantly-updated, AADR visualizer, researchers are now able to quickly and easily explore the available ancient human DNA for subsequent population genetic analyses. Moreover, this tool is ideal for educational purposes, reducing the barriers to entry for researchers new to human evolutionary genomics.

Abstract Name: Lexington's CORE Beliefs: How Local Kentucky Civil Rights Activists Considered Rises in Black Power and Radicalism, 1959-1970

Following the death of Martin Luther King Jr., civil rights organizations in the late 1960s faced pressure to debate the merits of non-violent strategies. This included the Congress of Racial Equality (CORE) which helped organize the 1963 March on Washington and other largely successful civil rights movements. Even its local chapters, such as Kentucky's oldest CORE chapter in Lexington, made huge strides in city desegregation, Black voter registration, and equal job opportunities. An interracial organization composed of professors, clergyman, and Black community leaders, Lexington CORE was initially dedicated to integration and nonviolence. Yet, by 1966, it can be seen that CORE was evolving into a Black Power organization, and Lexington was following. After the death of MLK Jr. in 1968, National CORE first championed 'Black Nationalism,' before unexpectedly slipping into conservatism and corruption. In the midst of this, individual CORE chapters were disrupted or even fell into infighting. This project seeks to better understand how local CORE chapters reacted to shifting consensus on Civil Rights, Black Power, and how to best combat racial discrimination. The study will analyze primary sources about Lexington, Kentucky's CORE Chapter using the Abby Marlatt Papers, 1945-2007, at the University of Kentucky Special Collections Research Center; oral histories interviewing former CORE members; and photos of protests organized by Lexington CORE. These sources will be put in dialogue with articles on Kentucky activism, civil rights, and how the National CORE evolved throughout the 1960s. The result will unravel how Lexington Civil Rights activists maintained their smaller-scale work given changes in national organization policies. Their efforts reveal the ways that local activists consider national issues and higher-ranked leaders when examining their own racial ideologies and communities.

Abstract Name: LRRK2-Mediated Phosphorylation of Rab12 Links Lysosomal Dysfunction to Early Tau Pathology

Leucine-rich repeat kinase 2 (LRRK2) mutations are the most common genetic cause of Parkinson's disease (PD). These mutations enhance its kinase activity, leading to hyperphosphorylation of Rab12, which may disrupt its role in coordinating lysosomal trafficking central to cellular clearance and protein degradation. Lysosomes contribute to protein aggregate degradation and are associated with the formation of granulovacuolar degeneration bodies (GVBs)—proteolytically active lysosomal vesicles that accumulate dense-core cargo and accompany early tau pathology. This study characterized phosphorylated Rab12 (pRab12) localization and its relationship to lysosomal GVBs and tau pathology using immunohistochemistry (IHC) and immunofluorescence (IF) in human post-mortem tissues and a tauopathy mouse model. In human samples, pRab12 labeling was analyzed across the hippocampus, temporal cortex, and frontal cortex of Alzheimer's disease (AD), dementia with Lewy bodies (DLB), LRRK2 G2019S Parkinson's disease (LRRK2-GS PD), and sporadic PD (sPD) cases. pRab12 labeled cytoplasmic puncta morphologically consistent with GVBs that colocalized with the GVB marker Casein kinase 1d (CK1d), demonstrating that phosphorylated Rab12 accumulates within GVBs. These pRab12-positive GVBs were significantly increased in all disease groups compared with controls and were most abundant at higher Braak stages (>3), particularly in the hippocampus. Beyond GVBs, pRab12 also labeled neurofibrillary tangles and dystrophic

neurites positive for AT8 in AD and DLB cases, suggesting a close association between Rab12 phosphorylation and tau pathology across both genetic and sporadic PD and other non-PD neurodegenerative diseases. In the PS19 tauopathy mouse model, pRab12-positive GVBs similarly increased with age and tau pathology. These puncta colocalized with CK1d and the lysosomal marker LAMP1, with significant triple-labeling for pRab12, CK1d, and LAMP1. GVBs were more abundant in the entorhinal cortex compared to the hippocampus, which paralleled regional patterns for AT8-positive tau accumulation. Together, these findings link LRRK2-mediated Rab12 phosphorylation to lysosomal dysfunction and early tau pathology across distinct neurodegenerative diseases.

Abstract Name: Developing a Systematic Framework for the Entanglement Renormalization of Fractal Spin Liquids

Quantum systems composed of many interacting particles can exhibit emergent phenomena that defy properties of their individual constituents. When these interactions occur through quantum entanglement, they can give rise to exotic quantum phases of matter with remarkable properties. One such phase is fracton order, a recently discovered class of quantum matter that differs sharply from conventional topological order. Specifically, they host quasiparticle excitations with constrained mobility. Some can move only along lower-dimensional submanifolds; others are completely immobile. These highly unusual behaviors make fracton phases both conceptually rich and potentially useful for robust quantum information storage. Despite growing interest, fracton order remains poorly understood. A hallmark of these systems is their bifurcating entanglement renormalization group (RG) flows, where the system effectively splits into multiple copies under coarse-graining, contrasting with the stable RG flows typical of other quantum phases. Here, we systematically study the entanglement renormalization of a class of (fracton) fractal spin liquids known as three-dimensional lineon codes. Our goal is to identify entanglement entropic signatures that characterize their distinct renormalization behavior. To this end, we compute key properties such as ground state degeneracy as a function of system size, providing insight into the structure and scaling of fracton entanglement.

Abstract Name: A Longitudinal Study of Black Student Experiences at SMU, 1950s-2020s

This project examines the history of inclusion and institutional support for the Black students at Southern Methodist University (SMU) from the 1950s to the present. Oral histories collected through the Voices of SMU project oral history project (VOSMU) contain the experiences of some of the university's earliest Black students and recent alumni to trace how opportunities and campus culture evolved over time. Early interviewees describe navigating racial isolation and challenges of integrating into a predominantly white institution. More contemporary interviewees show that increased diversity does not eliminate structural and cultural imbalances. This study is a thematic analysis of oral histories we gathered across multiple generations of Black students. The oral histories we conducted reveal that inclusion opportunities expanded significantly over time through the creation of Black student organizations, targeted scholarship initiatives, increased mentorship opportunities, and the development of more visible social spaces for Black students. Yet, these developments are unevenly matched by lasting cultural isolation. This study argues that Black student narratives capture forms of institutional change that official university records overlook. Their stories suggest that institutional inclusion has improved in structure but remains incomplete in practice because of the deeper cultural and historical dynamics that have shifted slower than institutional policy.

Abstract Name: Necessity and Application of Ion Gun Emissions on an Electrostatic Tractor Spacecraft

Because Geosynchronous Earth Orbit (GEO) represents a single altitude and inclination and is becoming saturated with noncompliant defunct satellites, it is imperative to implement debris remediation practices to avoid cascading collisions. Active debris removal from GEO can be achieved using the electrostatic tractor, where a servicer spacecraft aims an electron beam at a target debris object, charging the servicer positive and the debris negative, creating an attractive electrostatic force. This allows large spacecraft to be re-orbited to a disposal orbit. This research will expand on work done in the AVS Lab simulating the practicality of this concept. One challenge presented in previous work is that the size of the target can be significantly larger than the servicer. Due to this difference in capacitance, the servicer charges to its equilibrium potential before the target, resulting in a non-optimal electrostatic force. This work investigates how simultaneous ion gun emission from the servicer can mitigate this effect by counteracting the electron gun. The ion emission from the servicer causes a negative current, neutralizing the positive current from electron beam emission. The ion gun is used to maintain the servicer's potential while the target reaches its maximum potential. Simulations in MATLAB and SIMION will be central to completing this project. A search function is developed to find the ion gun current that coincides with a desired servicer potential. To determine whether each ion is able to leave the servicer without returning, a model of the electric potential field is created. The forces on the ion at each timestep are calculated. Based on preliminary results, the ion gun is expected to be an effective solution to the spacecraft capacitance issue when implemented alongside the electron gun for efficient electrostatic tractor interactions.

Abstract Name: 'Battle Against Time': Mortality and Memory in Proust's Photographic Collection

My research investigates how Marcel Proust's personal collection of photographs informs his literary construction of memory and time, specifically in relation to death, in *À la Recherche du Temps Perdu* (In Search of Lost Time). While scholars have long examined Proust's engagement with photography as a tool for memory, my project illuminates how photography is equally significant for his meditation on mortality, capturing the tension between obsessive preservation and inevitable loss. Observing that photographic imagery appears most prominently at moments of disappearance in the text, this study approaches Proust's work from both a visual and philosophical perspective. The research builds on existing scholarship on Proust's sensory and narrative techniques, as well as theoretical frameworks from Walter Benjamin and Bernard Stiegler that further examine Proust's relationship to death and the importance of technological memory. To deepen this analysis, I am conducting archival research in France, studying original photographs from Proust's collection held at the Bibliothèque nationale de France. This combination of a visual analysis of the archival photographs and close readings of key passages from *À la Recherche du Temps Perdu* engages with concepts from media philosophy to understand how photography operates as both evidence and elegy. I will demonstrate that Proust used photography not only to retrieve memory but to confront the impossibility of fully recovering what has been lost. The findings will contribute to the evolving, recent readings of Proust and will be discussed in the context of modernist studies, visual culture, and contemporary reflections on the role of technology in remembrance.

Abstract Name: Geometry-Driven Fibroblast Organization in 3D Bioprinted Microchannels

Three-dimensional (3D) bioprinting provides a versatile platform for studying how physical constraints influence collective cellular behavior. Scaffold architecture, particularly microchannel geometry and dimensions, governs group behavior by modulating cell-cell and cell-matrix interactions. In this study, we investigated the effect of microchannel width on NIH/3T3 fibroblast organization and maturation stages within biocompatible silicone scaffolds. Using a custom extrusion-based 3D printing platform, scaffolds with parallel channels of 300, 600, or 900 μm width are pre-fabricated. Fibroblasts suspended in Geltrex are then seeded into the channels and cultured for fourteen days under standard conditions. Cell group dynamics, alignment, and maturation stages are quantified using fluorescence imaging and live/dead assays on days 1, 4, 7, 10, and 14. Data analysis reveals that narrower channels (300 μm) promote strong alignment along the channel axis and dynamic temporo-spatial group/cluster behavior within the confinement. In contrast, wider channels (900 μm) allow lateral spreading and cluster formation. Intermediate channels (600 μm) have balanced alignment and spatial distribution, supporting both organized structure and uniform growth. We used machine learning algorithms based on the Kadomtsev-Petviashvili (KP) equation to analyze and predict how cells align and progress through maturation stages in different channel geometries (physical cues). Our results show that microscale confinement alone can guide group behavior and cellular development, even in the absence of biochemical cues. By adjusting channel geometry, this platform provides a controllable, physics-driven approach to studying how physical cues influence collective and dynamic cellular behavior. Overall, this approach not only offers a quantitative understanding of how spatial constraints shape tissue organization but also enables predictions that can inform the design of scaffolds for tissue engineering and regenerative medicine.

Abstract Name: A Granular-Based, Magnetically Controlled, Soft Robotic Gripper

Soft robotics is an ever-expanding field due to the technology's versatile and adaptable nature, with applications across wide-ranging sectors. Furthermore, the fusion of soft robotics with hard robotics has produced hybrid systems that have additional adaptability and durability. For our project, we have developed a hybrid soft/hard robotic gripper that utilizes a granular material for the gripping action. Granular materials, which are collections of athermal particles, exhibit a solid-liquid phase transition known as the jamming

transition. For example, sand can act like a liquid moving through an hourglass, but it can also act like a solid on the beach as it supports our weight. With this in mind, we developed a gripper that uses the granular jamming transition to grip objects when the granular material is jammed (solid-like) and release objects when the granular material is unjammed (liquid-like). The body was fabricated using 3D printing and is driven by the meshing of three 120° bevel gears. The gripper consists of three-prong style fingers, the ends of which have a flexible membrane filled with granular iron particles. Electro-permanent magnets were used to control the jamming of the fine iron particles entrapped in a flexible membrane. In the gripper, the magnets' constant field will jam the particle so as to be in a gripping state; once the field is turned off, the granular particles will be in the unjammed state. To date, we have designed and manufactured a working prototype. Our soft robotic gripper, with its adaptive and precise object-handling capabilities, holds significant promise for modernizing various sectors by enhancing machinery efficiency, streamlining operations, and minimizing spatial and cost requirements.

Abstract Name: Investigating the Interaction between Cortisol and the Phosphatidylinositol Pathway in Bipolar Disorder

Bipolar disorder (BD) is a debilitating psychiatric disorder characterized by recurring episodes of mania and depression. The cause of BD remains uncertain, however, the phosphatidylinositol signalling pathway is one of several pathways implicated in its pathophysiology. Specifically, myo-inositol levels differ in the manic and depressive phases, and myo-inositol depletion is proposed as a common mechanism for conventional mood stabilizers. Individuals with bipolar disorder often have dysregulated hypothalamus-pituitary-adrenal (HPA) axis activity resulting in elevated cortisol levels particularly during manic and depressive episodes. Additionally, myo-inositol has been shown to lower cortisol levels. This study explored a potential interaction between the phosphatidylinositol pathway and HPA axis dysregulation by examining the effects of cortisol on intracellular myo-inositol levels. Lymphoblastoid cell lines derived from individuals with BD were cultured in media containing varying concentrations of cortisol and myo-inositol levels were quantified in the cell extracts. Statistical analysis showed no significant differences in myo-inositol levels across the different cortisol treatments, indicating that variation in cortisol concentration did not produce measurable changes under these conditions. Overall, these findings suggest that while myo-inositol may influence cortisol levels, the reverse was not detectable in this experimental model.

Abstract Name: Borders in the Algorithm: A Comparative Study of U.S., Chinese, and French Large Language Models

This project investigates a central question at the intersection of technology and global politics: Do large language models (LLMs) reflect the geopolitical worldviews of the countries that develop them, and does a user's location influence what these systems say? Although LLMs are increasingly used in education,

journalism, and policy discussions, little is known about how they frame sensitive international issues or whether those framings vary across national contexts. Prior research has shown that U.S.- and Chinese-developed models sometimes encode differing ideological assumptions, but European systems and cross-regional testing remain understudied. To address this gap, this project extends an existing 50-question benchmarking method by examining three models—ChatGPT (United States), DeepSeek (China), and Mistral AI (France)—and by conducting the study from South Korea rather than the previously used location of Brazil. Using twelve geopolitically sensitive prompts, each model was first asked to predict how strongly the United States and China would disagree on a given topic, and then asked to produce full answers. These answers were anonymized and resubmitted to the models to evaluate how different the responses were from one another. This method captures both anticipated ideological conflict and actual differences in political framing. Preliminary results show that while most model responses appear similar on the surface, questions involving China consistently produced the highest levels of divergence and disagreement. DeepSeek's behavior changed most noticeably over time, shifting from refusing to answer certain questions to providing full responses, suggesting rapidly evolving moderation policies. Mistral AI often offered a broader historical context but did not fully avoid alignment with Western framings. These findings highlight the potential for LLMs to subtly shape global discourse and underscore the need for ongoing evaluation, transparency, and cross-national comparisons as these systems increasingly mediate public understanding of international issues.

Abstract Name: MicroRNA-Mediated Suppression of S100 β Expression in a C6 Neuronal Cell Model

S100 calcium-binding protein B (S100 β) is a member of the Calcium and Zinc binding family of proteins, and it is a crucial component of pro-apoptotic pathways that follow from traumatic brain injury (TBI), neurodegenerative diseases—such as Alzheimer's disease, Parkinson's disease, multiple sclerosis, and amyotrophic lateral sclerosis—, and even some psychiatric disorders. When activated, by either internal or external factors, it interacts with the RAGE receptor, a membrane-bound protein that, as a result of this interaction, releases reactive oxygen species (ROS), which themselves induce cascades of processes that result in neuronal death. One very promising approach to stopping this overt S100 β upregulation is through microRNA (miRNA) intervention. MiRNA is a small, endogenous molecule, usually varying between 19-25 nucleotides in length, that is essential for the regulation of protein expression; when produced, miRNA binds to either the 3'- or 5'-UTR of the target mRNA, and usually promotes the formation of a complex that cleaves the coding sequence so that the genetic code cannot be properly translated. Previous research has identified a number of possible S100 β mRNA binding sites for miRNA, but little has been done to test the effectiveness of these targets for future clinical applications. In this research, we aim at answering the question of whether the selected miRNA successfully binds S100 β mRNA to prevent the expression of the protein in vitro. The C6 rat neuronal cell line, known to express S100 β , will be treated with a miRNA solution that allows the molecule to penetrate the cell and influence its protein production; the effectiveness of the methodology will be assessed using a combination of ELISA and western blot protocols for detection of S100 β , which is expected to be partially or completely eliminated from the cell lysate.

Abstract Name: The Influence of Genetic and Environmental Risk Factors on Executive and Affective Abilities in Alcohol Use Disorder

Purpose: Alcohol Use Disorder (AUD) is a condition influenced by genetic, environmental, and psychological factors. Executive impairments are a strong marker of AUD severity; however, it remains unclear whether these impairments stem from genetic predisposition, actual alcohol consumption, and/or environmental exposures. Method: This study aims to determine the extent to which familial/genetic and environmental risk factors predict deficits in executive functions in a sample of individuals with severe AUD using polygenic score (PGS) for alcohol problems, family history of AUD (FH), and a sum score of adverse childhood experiences (ACE). Executive functions were indexed by inhibition (emotional Go/No-Go Task), attentional control (Attention Network Task), and shifting (Color-Shape Shifting task). We performed linear regressions with executive function performance as the outcome and PGS, FH, or ACE as main predictors. All models were controlled for sex, age, socioeconomic status, and current alcohol use. Results: Across tasks, better performance was observed among younger participants, females, and those with higher socioeconomic status. The roles of familial/genetic risk factors appeared specific for the inhibition task, while we found no significant associations between PGS/FH and shifting or attentional control. Results indicate that FH was linked to higher false alarm rates, reflecting weaker inhibitory control. Higher PGS was also related to poorer emotional discrimination of fearful, happy, and sad faces in the Go/No-Go Task. These effects were observed after controlling for alcohol consumption. However, we did not find evidence that ACE influenced executive performance in individuals with AUD. Conclusion: Findings suggest that genetic and familial factors contribute uniquely to affective executive dysfunction in individuals with severe AUD, beyond the effects of alcohol consumption. These results emphasize the multidimensional nature of cognitive deficits in AUD, with the roles of genetic/familial factors together with alcohol use patterns and severity.

Abstract Name: Energy Bandgaps Estimation and Alignment in Compound Semiconductors for Optoelectronic Applications

Bandgap alignment describes how the conduction and valence bands of two different semiconductor materials line up at an interface, determining the mobility of electrons and holes. Proper band alignment is essential for the efficient operation of optoelectronic devices. Compound semiconductors are of significant interest because, unlike silicon, many exhibit direct bandgaps that improve optical performance. In the first part of this research, a model was developed to optimize the bandgap energy of compound semiconductors as a function of the mole fraction of their constituent elements. Materials including InAs, GaAs, InP, GaN, and InGaAsP were modeled to determine the optimum bandgap by varying composition. The influence of the bowing parameter b in Vegard's law was also examined. At $x = 0.3$, the predicted bandgap (E_g) was approximately

1.13 eV, but decreased by $\sim 33\%$ to 0.80 eV when a bowing parameter of $b \approx 0.477$ was included. The second part of the work focused on band alignment in isovalent heterojunctions. ZnSe and CdSe were selected for band offset calculations. Because CdSe has a smaller bandgap, it acts as the quantum well, while ZnSe serves as the barrier material. Using Anderson's rule, the conduction band of CdSe was found to be 0.81 eV lower than that of ZnSe, and the valence band offset for ZnSe was approximately 0.17 eV. A MATLAB program was developed to plot the corresponding band diagrams, confirming that the ZnSe/CdSe heterojunction exhibits a Type-I band alignment. Additional results and discussion will be presented in detail.

Abstract Name: Revitalizing Observational Astronomy: Mastering Flat Fields

Revitalizing observational astronomy: mastering flat fields Sami Zain¹, Dr. Jennifer Carter¹¹. Susquehanna University, Department of Physics Flat field imaging is a cornerstone of photometry and usually can only be done with professional equipment which is beyond the budget of most. Because of how expensive this professional equipment can be, few may try to find a way around that by creating their own apparatus which can effectively collect flat field images. By applying all the basic principles to successfully obtain a flat field image, one can create a flat field imaging box which can mimic a professional setup, at a fraction of the cost. Comparisons between the apparatus and other methods of flat field imaging can then be done. As well, code can be developed in multiple languages, including Python and MATLAB, to analyze the processed flat field images to draw conclusions about the quality, as well as potential implications of these frames. The results and comparisons of the flat field images will be presented.

Abstract Name: Identifying Diagnostic Delays and Time to Final Diagnosis in Cancer of Unknown Primary

Cancer of Unknown Primary (CUP) is a rare and aggressive metastatic cancer in which the site of origin cannot be identified despite extensive diagnostic investigation. Timely progression through the diagnostic pathway is crucial, as delays can limit treatment decisions and worsen patient outcomes. To identify where these inefficiencies arise, this study reviewed patient records from the Cancer Centre (NHS UK), mapping key milestones from first symptoms to final diagnosis. Time intervals across referral, imaging, specialist evaluation, biopsy, pathology reporting, and MDT discussion were calculated to determine which stages contributed most to overall delays. The analysis found that the longest delays occurred between diagnostic imaging and biopsy, identifying this as the major bottleneck within the CUP pathway. Early delays between symptom onset and initial imaging also emerged, reflecting variability in referral urgency and limited access to early diagnostic services. In contrast, once biopsy samples were obtained, pathology processing and MDT review progressed more consistently and with fewer delays. Overall, these findings highlight the need for improved biopsy scheduling, stronger coordination between radiology and pathology, and expanded early

imaging access. Streamlining these steps may significantly reduce diagnostic lag and support more timely, effective care for patients with CUP.

Abstract Name: Design and Manufacturing of a General Purpose Adaptable Ejector Mechanism for the APSX-PIM Injection Molding Machine

Injection Molding (IM) is a cyclic process whereby molten plastic is formed into a desired shape by forcing it into a cavity under pressure. Sizes of molded parts vary from the smallest size components used in medical devices, to entire body panels of cars. IM is recognized as one of the most cost-effective technologies for producing high volumes of parts with consistent quality and intricate detail, making it essential for industries like automotive, medical devices, and consumer products. For rapid and efficient high-volume manufacturing, injection molding machines typically utilize a built-in mechanical, hydraulic, or pneumatic ejection system. This mechanism is designed to automatically and safely release the finished part from the mold, ensuring the process is efficient and the final product is free from defects. The selection of the appropriate ejection mechanism depends heavily on the part design, the required surface finish, the type of plastic material used, and production volume. Proper placement and type are essential to an efficient molding process and final product quality. To the author's knowledge, a single, universal, highly adaptable ejection system that can adapt to various mold geometries is yet to be designed and implemented. Which brings us to the subject of our current research. The main purpose of this study is the design and implementation of a general-purpose, highly adaptable ejection system for the APSX-PIM injection molding machine. The proposed solution employs tapered sleeves with slots to create powerful and precise clamps for the ejector pins precisely distributed over a mechanically operated ejector plate. The newer designs are expected to work with various mold geometries therefore effectively reducing tooling cost.

Abstract Name: Benchmarking the Generalization and Robustness of AI Models for Fake News Detection Across Political, Business, and Health Domains

With the widespread circulation of misinformation and deliberate information manipulation in the digital landscape, it has become increasingly challenging to distinguish between authentic material and fabricated content across social media and news platforms, invalidating the credibility of public knowledge. This research presents a principled benchmark comparing the performance of three advanced machine learning models and a combination ensemble model, in detecting fake news in Politics, Business, Health. This study provides an analysis in terms of overall accuracy, domain-specific versus cross-domain performances, and model robustness when exposed to new unseen contexts and subjected to controlled text modifications. Using a curated, balanced corpus of 20,000–30,000 fact-checked news articles sourced from public datasets from Politics, Business, and Health, multiple AI models – two discriminative transformative models (DeBERTa,

ELECTRA), a generative LLM model (Falcon-7B), and a combination of the transformative-LLM architectures – will be trained to detect heterogeneous misinformation patterns. To compare their strengths and weaknesses, model performances will be assessed in terms of Accuracy, Macro-Precision, Macro-Recall, Macro-F1, ROC-AUC, PR-AUC, and MCC, and ECE under three evaluation criteria: in-domain accuracy, reliability in cross-domain shifts, and adaptability when input text is modified. By means of rigorous statistical evaluation and testing, this research aims to report label distribution within the curated corpus while providing a comprehensive quantitative benchmark of performance under different evaluation criteria. This study seeks to contribute to the development of more reliable, socially responsible and transparent AI-driven misinformation detection mechanisms for maintaining the integrity of information ecosystems.

Abstract Name: Damned for All Time: Exploring the Relationship Between Queerness and Christianity Through Artistic Depictions of Judas Iscariot

Judas Iscariot is primarily remembered for his betrayal of Jesus. For centuries, depictions of Judas in art portrayed him as a traitor. Then, in the mid-twentieth century, when homosexuality became relevant in American Christianity, queer Christians used the arts to reclaim Judas as one of their own and to argue for a more accepting church. This paper explores queer Christianity as a lived experience by analyzing depictions of Judas in art. Texts from the early Christian church depicting Judas are analyzed to situate the author's perspectives in historical context. Artworks from Christian, queer, and non-affiliated creators from the mid-twentieth century onwards are then analyzed to explore the relationship between the American church and the queer community at the time. Depictions of Judas are sorted into four categories: empathetic, reject, sympathetic, and avoidant. Each category considers Judas' agency, religious context, fate, the work's overall thesis, and reception from the queer community and American church. Finally, a survey of queer Christians asking their perspectives on Judas is included. Samples of the artworks are expected to show a positive correlation between the rise of queer rights and empathetic depictions of Judas. Historically situated political and social sentiments on queerness are reflected in these Judas depictions. The survey of queer Christians are expected to show favorable views on Judas and people relating to him in creative ways. Judas reflects the lived experiences of queer Christians. Since the mid twentieth century, Christianity has been used to justify widespread bigotry. Judas spent nearly two millennia as a scapegoat, traitor, and villain. But his legacy has been redeemed with each work of queer art depicting him otherwise. My research encourages the American Christian church to redeem queer Christians the same way queer Christians reclaimed Judas: with re-examination, reflection, and a willingness to try again.

Abstract Name: Pecan Pie

Pecan Pie is an experimental short film in which a young woman scours her grandmother's house in search of the fairies that have sabotaged her Thanksgiving dinner. She is then given the unpleasant task of having to eat

the fairies in order to get rid of them. Made with a combination of video and animated illustrations woven together to create the air that fantasy is bleeding into reality. The imagery mimics first person puzzle games with the audience situated directly into the scene and treated as the protagonist: becoming the young woman and sometimes even the fairies. The narrative structure is inspired by Shakespearean comedies like *The Tempest* and *A Midsummer's Night Dream*, flipping between comedy and an uncomfortable tension. For as long as I can remember my family has gathered at my grandparent's house for Thanksgiving. They are however aging; footage used in *Pecan Pie* was taken at what was likely my last Thanksgiving there. Who will be hosting holidays next and carrying on the tradition was the topic we were all avoiding, but sat in our minds regardless throughout dinner. *Pecan Pie* engages both with the obligation to appease by carrying on family traditions as well as the responsibility someone might feel to leave convention behind if there is an underlying violence. Who is allowed to exist within a space is a common theme across my work. Mixed media collage and video are my mediums of choice. *Pecan Pie* is a culmination of the art I create. For the future of the project I plan to build upon what is already present to include oil painting illustrations and wooden sculptures as sets.

Abstract Name: Adapting the EPA SWMM Framework for Stormwater Simulation of a Utility-Scale Solar Farm in Fairfield, Virginia

As utility-scale solar photovoltaic (PV) installations become more common, understanding their effects on watershed hydrology is increasingly important. These systems create hybrid surface conditions in which impervious panels are elevated above pervious ground, producing runoff behavior not captured by traditional land-use categories. This study uses the EPA Storm Water Management Model (SWMM) to simulate surface runoff from a 50-acre solar farm in Virginia. To represent the hydrologic complexity of PV systems, each row of panels is divided into four sub-catchments: the panel surface, the dripline where concentrated flow occurs, the under-panel ground surface, and the vegetated spacer between rows. The model simulates both slope configurations within the same simulation. In the first case, the panel slope matches the ground slope, causing runoff to move downslope from both surfaces. In the second case, the panel slope opposes the ground slope, redirecting initial flow and altering infiltration patterns. The ground slope is held constant to isolate the influence of panel orientation, and hydrologic parameters, including soil characteristics, vegetation roughness, and rainfall inputs, are assigned using standardized regional data. Model results show that post-development peak flows are consistently higher than pre-development conditions, reflecting increased flow concentration at driplines and reduced infiltration beneath panel surfaces. Dense vegetation planted beneath and between solar arrays helps moderate these increases by adding surface roughness that slows overland flow. The outcomes highlight how vegetation type, panel configuration, and slope alignment can meaningfully shape hydrologic responses. Overall, the study demonstrates that SWMM can effectively represent runoff processes at solar PV sites by resolving microscale surfaces, simulating outfall volumes, and analyzing dual slope alignment scenarios within a unified model structure. Future work should incorporate field-measured slopes, conduit lengths, and dynamic panel angle adjustments to improve representation of tracking systems and enhance hydrologic realism.

Abstract Name: Quantifying Acrolein Levels in E-Cigarettes to Assess Rising Non-Cancer Risk

Acrolein is an aldehyde that is produced through thermal decomposition (pyrolysis) of components such as propylene glycol and vegetable glycerin, the main components of E-Cigarettes. This substance contributes to respiratory and cardiovascular toxicity. With the rapid increase in the consumption of E-Cigarettes, health alerts have been generated regarding exposure to acrolein. For this reason, this study is based on analyzing previously published data on acrolein emissions from commercial electronic cigarette products (Ogunwale et al., ACS Omega, 2017) to quantify exposure levels and evaluate the Non-Cancer Risk Index (NCRI) at 10, 20, 30, and 40 inhalations per hour. The NCRI was calculated by dividing the acrolein yield per inhalation by the Non-Cancer Reference Exposure Level (REL) for acrolein (0.00002 mg/m^3), multiplying by the reciprocal of the daily breathing rate ($1/20 \text{ m}^3/\text{day}$), and adjusting per inhalation. This formula was based on the toxicological evaluation framework described by Fowles and Dybing (2003). As a result, many of the products exceeded the NCRI threshold of 1.0, with values increasing as inhalations per hour increased. Notably, the products Halo Cafe Mocha and Halo South Classic reached NCRI values far above the threshold, which emphasizes a greater risk of non-cancer effects, such as respiratory or cardiovascular problems over a lifetime. The data demonstrate that the daily use of E-Cigarettes can generate a concerning exposure to acrolein and highlight the need for regulatory oversight to reduce possible non-cancer health risks.

Abstract Name: The effects of delta-9-tetrahydrocannabinol on a methicillin resistant strain of staphylococcus aureus

Methicillin resistant *Staphylococcus aureus* (MRSA) is a bacterium that possesses a penicillin binding protein with a weak affinity for beta-lactam antibiotics. MRSA is a major contributor to hospital-acquired infections and has a high mortality rate. While β -lactam antibiotics have served as a primary treatment, MRSA's growing resistance has prompted the search for alternative antimicrobial agents. One emerging candidate is delta-9-tetrahydrocannabinol (THC), the primary psychoactive compound in *Cannabis sativa*, which has gained research attention due to its potential therapeutic properties. In this study, the MRSA strain ATCC 43300 was exposed to varying concentrations of THC in combination with the antibiotics cefoxitin and oxacillin. The aim was to evaluate potential synergistic effects between THC and standard antibiotic treatments. The results indicated no significant synergistic interaction between THC and the tested antibiotics, but there was a strong dose-dependent antimicrobial effect of THC. Notably, the minimum inhibitory concentration (MIC) of THC required to achieve inhibition of MRSA growth was comparable to the MICs of many standard antibiotics. These findings suggest that THC has direct antimicrobial activity, highlighting the clinical potential of cannabinoids for treating infectious diseases. This prompts further investigation into the pathways and implications of cannabinoid use in treating antibiotic-resistant bacterial infections.

Abstract Name: Regulating the Runway: Investigating the Effects of Kentucky Governmental Policies on its Aviation Industry and Projecting Future Outcomes

Despite its small population and rural nature, could Kentucky have been at the forefront of aviation transit in the mid 20th century? States such as Florida and Texas followed Kentucky's policies on tall building regulations around airports in the early 1980s. When Kentucky first created their Department of Aviation in 1948, they organized it to directly report to the governor, but later the department became a division underneath the Department of Transportation and its labor force greatly reduced. This decision created disruption among many within the department, including Edward Lafontaine, who was appointed director of the Kentucky Office of Aeronautics in 1975. Lafontaine's accomplishments include opening over 60 municipally-owned airports and establishing the first successful state aviation program in the nation. Utilizing documents from the Edward Lafontaine Papers, 1969-1992, at the University of Kentucky Special Collections Research Center and contemporary Federal Aviation Administration (FAA) data, this study aims to qualitatively and quantitatively determine the effect departmental regulation had on air travel in Kentucky. FAA data such as passenger statistics and economic impact studies, will provide a basis for quantitative analysis. The study aims to assess the extent to which the lack of Kentucky's Department of Aviation affected the state's aviation trajectory. To further expand this research, I will use current data to create a future impact model estimating the effects of current day federal aviation legislation.

Abstract Name: Low-Cost Attitude Determination for CubeSats Using Sensor Fusion

Accurate attitude, or orientation, determination is critical for CubeSat missions, yet high-precision sensors (accuracies $< 0.1^\circ$) cost \$10,000+ while most undergraduate missions only require $< 5^\circ$ accuracy. Low-cost alternatives for this performance tier remain underdeveloped and unvalidated. This research addresses the challenge of achieving reliable attitude estimation using low-cost components: silicon photodiodes as sun sensors, a three-axis magnetometer, and a six-axis inertial measurement unit (IMU). We developed an attitude determination and control system (ADCS) that integrates six photodiodes, one on each face of the CubeSat, with a magnetometer interfaced via I2C protocol to a Raspberry Pi 4B. The photodiodes, coupled with an analog-to-digital converter, detect solar illumination to compute sun vectors in the body frame, while the magnetometer measures the local magnetic field vector, also in the body frame. We implemented the Two-Vector TRIAD algorithm to fuse the body-frame sensor measurements with the inertial-frame reference vectors to estimate the spacecraft's attitude. These estimates are then combined with IMU readings using a Multiplicative Extended Kalman Filter (MEKF), providing continuous attitude estimation while accounting for sensor uncertainties and measurement noise. Key challenges included fusing measurements from the sensors with varying noise characteristics and update rates (ranging from 1-1000 Hz), validating accuracy without expensive equipment (e.g., Helmholtz cages, air-bearing platforms, or rate tables costing \$10,000+), and establishing repeatable testing procedures for performance characterization. An Ossila solar simulator provided realistic illumination while static and dynamic testing protocols were developed using a stepper motor setup to quantify the system's measurement accuracy. Preliminary tests show attitude estimates within the target $< 5^\circ$ accuracy range during static tests. Further results will benchmark the performance of this affordable sensor configuration and demonstrate its potential for future CubeSat missions. This work enables future integration with control algorithms and provides a testing framework for low-cost ADCS development in undergraduate research programs.

Abstract Name: Modeling Mechanical Stimulation of Cancer in High Sugar Tissue

Throughout 2025, 30,000 people died of liver cancer in the U.S. Furthermore, liver cancer incidence around the world is projected to increase, and type 2 diabetes is partially implicated. A potential reason is that excessive sugar in tissue, a symptom of type 2 diabetes, can react with proteins to form advanced glycation end products (AGEs). These AGEs crosslink collagen to modulate the tissue's viscoelasticity, or its balance between being a viscous fluid and elastic solid. Recent findings suggest such viscoelastic modulation then alters cancer and immune cell behavior in the tumor microenvironment, but the responsible mechanisms are underexplored - especially in the context of type 2 diabetes. Hence, there is a crucial need for quick-to-produce experimental models to study cell behavior in high-sugar, viscoelastic environments. Ultimately, the objective of this project is to develop said model as a collagen hydrogel. Collagen is first tested with treatments of prepared AGEs, or methylglyoxal, glucose, or ribose to induce glycation. Following collagen gelation, two methods monitor hydrogel crosslinking: SDS-PAGE monitors molecular weight for fiber aggregation, and HPLC monitors amino acid composition for reacted groups. The viscoelastic properties of the hydrogels are measured via shear rheology. After the optimal treatment is determined, cancer cells and macrophages are seeded into the finalized hydrogel, and confocal imaging tracks migration. Machine learning algorithms analyze this data for how viscoelastic manipulation affects seeded cells. Based on literature, sugar crosslinking treatment is expected to maintain stiffness while accelerating the hydrogel stress relaxation rate, or the rate which resistance to deformation decreases over time. Cancer and pro-cancer immune cells are expected to become more motile in this fast-stress-relaxing context, reflecting a dangerous tumor microenvironment. Overall, this investigation will produce a hydrogel model relevant to liver cancer and elucidate the impact of viscoelasticity on cancer in high sugar tissue.

Abstract Name: Proactive Personality, Reciprocal Dynamics, and Creative Performance in Global Virtual Teams: An RI-CLPM Study

In global virtual teams, creative performance is influenced by both stable individual traits and dynamic moment-to-moment behaviors. Guided by Social Cognitive Theory and Conservation of Resources Theory, this study examines how proactive personality predicts stable engagement and creativity, and how within-person fluctuations in effort and creative idea quality influence one another across time. Utilizing a four-wave longitudinal design and RI – CLPM framework, we successfully distinguished stable between – person tendencies from momentary within-person changes. This analysis yielded a discernible reciprocal effort–creativity cycle: when individuals engaged more intensely than usual at time t , they produced higher-quality creative ideas at time $t+1$ ($\beta = 0.180$, $p < .001$). Conversely, periods of heightened creativity contributed to

increased engagement in subsequent phases ($\beta = 0.078$, $p < .001$). Despite its bidirectional nature, the effect from effort to creativity was found to be notably stronger, suggesting that effort functions as a primary resource that initiates a Creative Resource Gain Spiral across time. At the between-person level, individuals with more stable proactive tendencies consistently exhibited higher levels of average engagement ($\beta = 0.119$, $p < .001$). The accumulation of engagement resources resulted in significant cross-level consequences, with stable effort exhibiting a strong prediction of distal team creative performance ($\beta = 0.816$, $p = .029$). This underscores the role of enduring individual resource investment in shaping collective creative outcomes within global virtual teams. This study is among the first to use an RI-CLPM framework to demonstrate a bidirectional effort - creativity cycle within global virtual teams and provides new evidence for dynamic resource processes in distributed collaboration. At the team level, contextual characteristics such as average team age and time zone dispersion also emerged as significant predictors of creative outcomes. These findings highlight the significance of demographic composition and temporal structure in fostering creativity within virtual team environments.

Abstract Name: Stepping Up or Staying Silent: Language Barrier Effects on Leadership-Communication Dynamics in Global Virtual Teams

This study aimed to investigate the longitudinal associations between perceived internal and external language barriers and leadership and communication perceptions in global virtual teams. We analyzed multi-wave longitudinal data from 1,520 students (in 324 teams) participating in an 8-week global business competition (X-Culture, 2022 Fall). To disentangle stable (i.e., between-person) differences from dynamic (i.e., within-person) relationships, we employed the Random-Intercept Cross-Lagged Panel Model (RI-CLPM). At the between-person level, results revealed that internal language barriers (i.e., self-perceived expressive difficulties) were significantly negatively associated with both stable leadership ($\beta = -0.130$) and communication traits ($\beta = -0.101$). Conversely, external language barriers (i.e., perceiving difficulties in others' communication) were significantly positively associated with stable leadership traits ($\beta = 0.058$) but showed no significant association with stable communication traits. At the within-person level, we examined the reciprocal dynamic relationships, revealing an evolutionary pattern. The path from communication state to the subsequent leadership state emerged mid-project ($\beta = 0.106$) and was sustained. The reverse path—from leadership state to communication state—was initially non-significant, but emerged strongly in the later stage ($\beta = 0.196$), indicating a shift from a unidirectional to a reciprocal dynamic. These findings suggest that team-level communication challenges (external barriers) may create a leadership vacuum, which individuals fill by “stepping up,” thereby earning higher stable leadership ratings. However, within the dynamic weekly interactions, communication acts as the initial driver for leadership, which later evolves into a reciprocal loop where both processes mutually strengthen each other over time.

Abstract Name: A Tale of Two Motivations: How Goal Orientations Shape Language Barrier Effects in Global Virtual Teams

This study aimed to investigate why the effects of language barriers on communication quality vary across individuals. We examined whether two distinct motivational dispositions – Learning Goal Orientation (L-GO) and Performance Goal Orientation (P-GO) – act as moderators for the relationship between language barriers and communication quality. We analyzed data from 1,520 students (in 324 teams) participating in an 8-week global business competition (X-Culture, 2022 Fall) using a multilevel moderation model. Results revealed a “tale of two motivations”: Learning Goal Orientation (L-GO) did not emerge as a significant moderator, suggesting that communication behavior for high-L-GO individuals remains stable regardless of contextual barriers. Conversely, Performance Goal Orientation (P-GO) acted as a powerful moderator, revealing a “double-edged sword” effect. First, P-GO significantly amplified the negative impact of internal barriers on communication ($B = -0.075$); for high-P-GO individuals, self-perceived expressive difficulties (internal barriers) appear to trigger a “fear of looking incompetent,” causing communication quality to deteriorate sharply. Second, P-GO also moderated the effect of external barriers, but in the opposite direction ($B = 0.050$); high-P-GO individuals seem to frame team-level communication challenges (external barriers) as a “legitimate challenge,” motivating them to compensate and improve their communication. These findings indicate that the impact of language barriers is not universal but is contingent upon an individual’s motivational framework.

Abstract Name: Left vs. Right: Computational Insights into Neuron Asymmetries and Impact on Bladder Pain

The brain region known as the central nucleus of the amygdala (CeA) plays a crucial role in modulating bladder pain. Research has shown that in the context of bladder injury, the left CeA is generally anti-nociceptive, meaning it decreases pain, while the right CeA is generally pro-nociceptive, meaning it increases pain. CeA neuron populations that express protein kinase c-delta (PKC- δ), calcitonin gene-related peptide receptor (CGRPR), and phosphorylated extracellular signal-regulated kinase (pERK) contribute to pain signaling within both left and right hemispheres through their distinct asymmetric firing properties and specific responses to injury. This raises a central question for our work: Can these asymmetries in neuron-level properties drive the progression of bladder-pain output from the CeA? We developed a 3-D agent-based computational model of the left and right CeA to investigate how hemispheric asymmetries in these neuron populations influence emergent pain output during bladder injury. Our agent-based model simulates the location, connectivity, and firing rates of more than 24,000 PKC- δ , CGRPR, and pERK co-expressing neurons with detailed spatial and functional properties. Simulation of the model yields an emergent measure of pain-related output from the left and right CeA in response to bladder injury. Model parameters were estimated from wet-lab data showing clear left-right differences in neuron firing rates and pERK expression in the CeA, allowing the model to reflect experimentally observed neuron activity patterns across hemispheres. The model uses neuron data from eight mice to capture natural variability. Simulations from the model show how left-right differences in neuron-level properties can impact system-level pain output from the CeA. Mice with higher initial pERK expression exhibit greater pain responses, with firing-rate

asymmetries emerging as the primary contributor to pain and with pERK asymmetries further amplifying pain following injury.

Abstract Name: SteMy: Designing Robotic Assistants to Support Stem-Cell Research

The use of social companion robots has been explored in a variety of settings, but their application in stem cell research for conducting differentiation of human pluripotent stem cells has not been explored. Although stem cell research offers great promise for advancement regarding human health, the culture and differentiation of stem cells remains highly variable and technically complex. Researchers face persistent challenges such as workflow inefficiencies and cognitive fatigue, potentially creating a bottleneck in the research process. These complexities present an opportunity for a robotic assistant to support laboratories that work with stem cells. To address this challenge, we conceptualized SteMy, a social companion robot designed to address the challenges of stem cell research. This study explores the design of a robotic assistant to support stem cell researchers without replacing human agency. Using participatory design methods, we engaged stem cell researchers, particularly those of human pluripotent stem cell-derived cardiomyocytes (hPSC-CM), in (1) an introduction to SteMy, a social companion robot tailored to hPSC-CM research, (2) a participatory session to identify design implications for robot assistants, and (3) a survey to capture researchers' perceptions of the integration of SteMy into their lab environment. Our findings contribute to HRI by highlighting design implications for a robotic assistant that support stem cell researchers.

Abstract Name: Adaptive Laboratory Evolution of *Acidithiobacillus ferrooxidans* for Vanadium Oxidation to Understand Genomic Determinants of Metal Selectivity

Metals bind to metalloproteins for diverse functions, including electron transfer, structural stability, and catalysis. However, the molecular basis of metal selectivity is often unclear. Here we attempt to evolve Af variants capable of oxidizing V³⁺ in place of Fe²⁺ using adaptive laboratory evolution for genomic analysis of mutations in Cyc2 and genes that influence metal selectivity. The outer-membrane c-type cytochrome Cyc2 recognizes Fe²⁺ in *Acidithiobacillus ferrooxidans* (Af), a chemolithoautotrophic acidophile that oxidizes Fe²⁺ and sulfur for energy under aerobic conditions. Cyc2 is the proposed first electron acceptor in the aerobic Fe²⁺ oxidation, but it remains unknown whether Fe²⁺ specificity is encoded solely by Cyc2 or from

interactions with other proteins. We hypothesized that adaptive laboratory evolution could yield Af variants capable of V³⁺ oxidation. We chose V as the alternative donor due to its chemical similarity to Fe and ability to sustain Af growth in Fe²⁺/V³⁺ mixed media via indirect redox cycling. Genetic diversity was generated by exposing Af to UV irradiation for one minute, followed by selection in media containing V³⁺ as the only available electron donor under aerobic conditions. Because V³⁺ is unstable in aerobic conditions, we also evaluated selection anaerobically to minimize abiotic oxidation. Together these experiments aim to test whether an Af variant that oxidizes V³⁺ can be developed for genomic analysis. This can provide insights into whether mutations in Cyc2 alone broadens donor usage or whether changes elsewhere are required, informing pathway-level constraints on engineering metal-specific oxidoreductases for biotechnological applications, including mining or electrofuel generation.

Abstract Name: Is ChatGPT a fanfiction author? Literary analysis of AI chatbot-generated fanfiction

Since the rise in accessibility of generative AI chatbots, the use of applications like ChatGPT has skyrocketed, particularly for writing. Numerous studies have been conducted to examine the implications of these AI chatbots, examining the efficacy of these programs, the experience of co-writing with AI, and the structural and societal changes AI may bring to the craft of writing. While studies have considered generative AI chatbots in the context of creative and scientific writing, there are few studies that focus on the genre of fanfiction, a unique form of creative writing that draws upon media (literature, film, TV shows, etc.) or real life people. This research project examines the quality, content, and features of four fanfiction stories generated from prompts varying in detail and length. The subsequent analysis focuses on the stories' literary elements of plot, setting, and character, as well as features such as faithfulness to the original medium and execution of the fanfiction writing style. Findings show that while AI chatbots can successfully generate fanfiction based off of an existing medium, the stories are short, often lacking in detail and character development, and contain inconsistencies. With the current limitations of AI chatbots, it is unlikely these applications will be able to produce fanfictions that match the quality and literary levels of human writers. However, chatbots' capability to generate passable fanfiction—as well as its unethical data scraping of existing fanfiction works—may cause concerns and tension in fan communities. These communities should be prepared for generative AI to change the landscape of fanfiction in the coming years.

Abstract Name: The Moral Cost of Agreement: A Quantitative Benchmark of Sycophancy in Large Language Models' Moral Reasoning

Large language models (LLMs) are increasingly being utilized in high-stakes domains such as healthcare, defense, and education. However, these models exhibit “sycophancy,” the tendency to generate biased outputs that align with a user’s desires. As LLMs increasingly participate in decision-making that affects lives, understanding how they align with user biases has become critical to ensuring ethical artificial intelligence (AI) behavior. Current literature has quantified sycophancy in objective areas such as mathematics and healthcare, but there is a lack of research analyzing this phenomenon in subjective moral decision-making. This study seeks to establish a quantitative benchmark for measuring sycophancy across varying levels of user bias. Moral scenarios across different ethical domains are generated using a human-in-the-loop workflow with reliability assessed using Fleiss’ Kappa. Using a bipolar Likert scale (-5 to +5), we quantify the magnitude of moral sycophancy in Gemini and GPT models by analyzing the difference in moral ratings between neutral baselines and user-biased prompts. Using a paired sample t-test approach on the difference scores, we identify which models and scenarios are most susceptible to shifts in moral judgment toward user bias. These results are reported with statistical confidence intervals (95%) and visualized using Box-and-Whisker plots to display the distribution and skew of model responses. We expect a consistent vulnerability in current models to prioritize user validation over ethical consistency. By illustrating sycophancy across ethical domains, this study reveals where current AI parameters fail and proposes a framework for benchmarking moral consistency in LLMs. This is critical for policymakers and developers in creating standardized safety benchmarks that evaluate moral consistency.

Abstract Name: Optimal Ordering Decisions in a Two-Period Newsvendor Problem with Partial Backorders

This project examines how a company should decide how much to order when selling a seasonal product over two periods with uncertain demand. The study builds on the classic newsvendor problem, which determines the optimal order quantity when demand is unknown, and extends it to a two-period setting. In this version, demand is uncertain in both periods, and if some customers cannot purchase the product in the first period, a portion of them may return in the second—a situation known as partial backordering. The central research question is how firms can determine the optimal ordering strategy that maximizes profit while balancing the risks of overstocking and understocking. To address this question, we develop a mathematical model that incorporates key factors such as demand uncertainty, inventory holding costs, and the probability that unsatisfied customers from the first period return to buy in the second. The model allows the firm to determine how much to order before each selling period and how to respond to leftover inventory or unmet demand. We then conduct sensitivity analyses to examine how profit and ordering decisions change under different market conditions, including variations in demand variability, customer return rate, and product holding cost. Preliminary results indicate that the optimal ordering policy is highly sensitive to the fraction of customers who return in the second period. When even a modest proportion of customers come back, expected profit can increase substantially compared to assuming no backorders. These findings suggest that firms can improve profitability by explicitly accounting for customer return behavior in their order decisions. The project demonstrates how mathematical modeling can provide practical insights for inventory management and decision-making in industries dealing with seasonal goods, such as holiday merchandise, and perishable products.

Abstract Name: Comparative Genomic Analysis of Gene Transfer Agents in Methanogenic Archaea and Beyond

Gene transfer agents (GTAs) are virus-derived particles that package random fragments of host DNA and are released through death of producing cells, aiding in horizontal gene transfer and recombination. Their existence poses an evolutionary puzzle: although GTA production is individually detrimental, GTA genes show evidence of long-term purifying selection, suggesting benefits that emerge at the population or lineage level. Voltae Transfer Agents (VTAs), produced by a methanogen *Methanococcus voltae* PS, are the only known archaeal GTAs. Are GTAs more widespread in Archaea than we currently know? My project aims to search for VTA relatives in other methanogenic archaea to examine their origins and evolutionary history. To address this, I investigated the distribution of VTA proteins from *M. voltae* PS across all *M. voltae* strains and the broader class *Methanococci*. First, I assembled a comprehensive genomic dataset of publicly available RefSeq and GenBank assemblies for *Methanococci* and relevant bacteria occupying similar environments. Using VTA proteins as queries, BLAST analyses of four *M. voltae* genomes identified clear homologs of all query proteins, each in tight genomic proximity indicative of conserved clustering. Assessing their evolutionary breadth, iterative PSI-BLAST searches against available *Methanococci* found homologs in 35 additional strains, six of which encoded homologs for at least half of the query proteins. In all substantial matches, the recovered homologs formed compact genomic neighborhoods, suggesting strong selective pressure to maintain cluster structure across *Methanococci*. Curiously, homologs of tail proteins were found in distantly related strains belonging to *Firmicutes* and *Cytophaga*, *Fusobacterium*, and *Bacteroides* (CFB) group bacteria. To examine if these proteins were horizontally exchanged, I reconstructed evolutionary histories of VTA and VTA-like genes and compared them to organismal relationships. Together, these analyses aim to clarify how VTA clusters persist despite individual-level costs, providing insights into the evolutionary processes that shape viriform genetic exchange mechanisms in microbial populations.

Abstract Name: STING Agonists Inhibit Kaposi's Sarcoma-Associated Herpesvirus Pathogenesis

Kaposi's sarcoma-associated herpesvirus (KSHV) is an etiological agent of multiple malignancies associated with compromised immunity, such as Kaposi's sarcoma (KS) and primary effusion lymphoma (PEL). KSHV infection is lifelong and there are currently no specific treatments for KSHV-related diseases, presenting an urgent need for therapeutics. The cGAS-STING DNA-sensing pathway is known to activate the type I interferon response and induce growth inhibition and/or cell death in cancer cells. Therefore, STING agonists, which mimic the enzymatic products of cGAS, have shown potential as effective antivirals and cancer therapeutics and are being tested in nonviral cancer-related clinical trials. This study seeks to expand this approach to viral cancers, which are understudied and make up approximately 15% of all cancers. In this

study, we report that the treatment of KSHV-infected BCBL1-trex-luc primary effusion lymphoma cells with diamidobenzimidazole (diABZI), a potent STING agonist, significantly inhibited KSHV lytic replication, reflected by attenuated viral gene transcription, DNA replication, protein expression, and virion production. Under latent conditions, patient-derived PEL cell lines were treated with diABZI and exhibited decreased cell growth and viability. Our RNA-sequencing revealed an upregulation of interferon-stimulated genes (ISGs) and cell death pathways including apoptosis and autophagy. These results provide a foundation for STING agonists as a potential therapeutic option for KSHV-driven diseases.

Abstract Name: Extraction and Quantification of Fluoxetine (Prozac) in the Aqueous Environment

Fluoxetine, better known as Prozac, is a commonly prescribed antidepressant. It has been known to persist in wastewater systems, meaning that it can potentially enter the aqueous environment and cause harm to aquatic life. The purpose of this project is to develop effective methods to quantify fluoxetine in water samples using liquid chromatography-mass spectrometry (LC-MS), as well as observe partitioning effects onto polyethylene microplastics. Since the concentration of any fluoxetine found in natural water is expected to be below the detection limit of the LC-MS instrument, it is necessary to develop a method to extract Prozac from the aqueous samples and concentrate it for analysis. Initially, aqueous samples were prepared with a known concentration of Prozac. A solid phase extraction (SPE) method has been optimized with Oasis MC-X cartridges that can capture Prozac molecules and concentrate the samples for analysis with LC-MS. Different variables of sample preparation, such as the volume of samples, salinity of water, acidification, and the presence of microplastics have all been taken into account to determine how Prozac behaves in the aqueous environment. For quantification, a six-point calibration curve was created with internal standardization using fluoxetine-d6. The aqueous fluoxetine standard concentrations ranged from 0 mg/L to 12.5 mg/L with concentration of 1 mg/L of deuterated fluoxetine in each standard, giving a 1 to 10 signal ratio of deuterated fluoxetine to fluoxetine.

Abstract Name: Artificial Intelligence Based Defect and Quality Detection for Manufacturing Through Depth Perception

Image-based perception has grown to become a cornerstone of modern autonomous systems, and is widely implemented in artificial intelligence models for quality inspection, and object recognition with traditional computer vision methods relying solely on RGB-imagery. While effective for many applications, RGB-based approaches struggle to capture subtle, low-contrast changes in contours and curvature. These limitations can significantly reduce detection accuracy in real-world environments, particularly in low-light conditions such as manufacturing and warehouse automation. To address this societal need, this project investigates how incorporating stereovision depth perception as an additional sensing modality to RGB imagery can enhance the detection of surface deformations that standard vision systems can often miss. The central hypothesis of

this project is that adding depth information to RGB imagery will enable more reliable detection of subtle surface defects than RGB-based methods alone. Although depth sensing is increasingly accessible, a clear technical need remains for vision systems capable of detecting subtle, three-dimensional surface defects that RGB imagery alone often cannot capture. Relatively few defect-detection systems fuse depth and RGB information, and even fewer explore how depth specifically improves sensitivity to minor shape irregularities. This work develops a depth-augmented perception pipeline that first identifies the target object in an RGB image, and then analyzes its corresponding depth geometry to determine whether local deformations are present. The preliminary results from a trained RGB-only model developed in this project depict an average confidence rating of 80%, and early literature review reveals a potential improvement of roughly 10% with F1 scores reported in the range of 0.898-0.914 for multimodal approaches. Further work will involve collecting paired RGB and depth data across five distance bands, multiple object orientations, and slightly varied lighting conditions. Depth gradients and local curvature will be used to identify shape deviations such as dents and bulges.

Abstract Name: When Caring Hurts: Exploring the Link Between Empathy and Secondary Trauma

Empathy plays a critical role in trauma-related professions, where practitioners are routinely exposed to the emotional suffering of others. The motivation for this study was to explore whether individuals who have experience working or volunteering with trauma-exposed populations report higher levels of empathy compared to those without such experience. This question stems from prior research suggesting that trauma work may enhance empathic sensitivity while simultaneously increasing vulnerability to emotional strain (Figley & Ludick, 2017; Wagaman et al., 2015). Participants (N = 162, ages 18–71) were recruited through outreach to a university community and various trauma-informed agencies across Oklahoma. They completed an online Qualtrics survey that included demographic questions, an empathy scale adapted from the Empathy Quotient (Muncer & Ling, 2006), and items modeled after the Secondary Traumatic Stress Scale (Bride et al., 2004). An independent samples t-test revealed that participants with trauma-related experience reported significantly higher empathy scores ($M = 52.79$, $SD = 6.38$) compared to those without such experience ($M = 50.34$, $SD = 7.35$), $t(160) = 2.015$, $p = .046$. While no significant differences were observed in secondary traumatic stress symptoms, the pattern of results supports previous findings on the emotional impact of trauma exposure. This work highlights the importance of trauma-informed training and supervision and encourages future research on empathy development in high-stakes environments.

Abstract Name: I Feel You, But Can I Remember? The Impact of Courtroom Environments on Mirror-Touch Synesthetes

Mirror-Touch Synesthesia (MTS) is a rare condition affecting approximately 2% of the population, in which individuals experience vicarious physical sensations when observing touch to others. This study explores how MTS may influence empathy, decision-making, and emotional reactivity, particularly within courtroom environments. Participants (N = 204) were adults recruited via email, SONA, and social media who completed an online Qualtrics survey. The survey included videos depicting human touch, the Facial Expression Recognition Test (36 stimuli), and a shortened version of the Empathy Quotient. Results indicated a significant positive correlation between MTS responses and cognitive empathy ($r = .16$, $p = .02$), but no significant relationships with emotional or social empathy. The second phase of this research involves a mock jury simulation designed to examine whether empathy mediates the relationship between MTS and decision-making and whether this effect is amplified by emotionally charged evidence. Findings aim to shed light on how sensory-empathic experiences may affect judgment processes in legal contexts, offering implications for understanding bias, emotion, and perception within courtroom environments.

Abstract Name: Law Enforcement Officers' Perception of the Threshold for Reasonable Suspicion

Since its inception in 1968, reasonable suspicion, defined as a set of circumstances in which a reasonably prudent person would believe that a crime is in the process of, or has been committed, has been a doctrine shrouded by confusion. Over the years, many cases have gone before the Supreme Court, and although the concept of reasonable suspicion has been refined, questions still remain on what constitutes the minimum threshold of reasonable suspicion and even the definition of 'reasonable'. A previous study has found that law enforcement officers do conform to the legal requirements of reasonable suspicion (Mclean Et al, pg. 6), but a hole in the research exists when it comes to law enforcement officers' perception of the doctrine. Therefore, this study asks at what criteria do Law Enforcement Officers perceive that they have crossed the threshold from mere suspicion to reasonable suspicion and if this perception varies among length of experience in law enforcement, gender, education, or agency size. This study aims to address that question via an online survey administered to Texas law enforcement officers. The officers were recruited in a convenience sample via the Sheriffs Association of Texas and the Texas Chiefs Association. The respondents were asked to evaluate several real life scenarios that have gone to appeals courts by rating whether or not reasonable suspicion exists in each case and how likely they would be to prolong the stop. Once the results are compiled the responses will be separated into separate demographic groups and compared. It is anticipated that the results of this study will give a better understanding as to the level of variance in the perception of reasonable suspicion among separate law enforcement demographics which will aid law enforcement agencies in evaluating the consistency in officer behavior when dealing with potentially criminal conduct.
